The corresponding enzyme in invertebrates, arginine kinase, was originally thought to exist only as a monomer of molecular weight about 40,000 (refs. 5–7). More recently arginine kinases with a molecular weight of about 80,000 have been found among the annelids<sup>8</sup> and echinoderms<sup>1,8</sup>. By comparison with creatine kinase these enzymes have also been assumed to be dimers although this still remains to be formally demonstrated. The two types of arginine kinase appeared to be representative of particular species. Multiple forms of the monomer arginine kinase have been demonstrated by starch gel electrophoresis<sup>9</sup>, but no attempt was made to correlate these with a particular function.

The present communication reports the discovery in some molluscs of the 80,000 molecular weight arginine kinase together with the 40,000 molecular weight enzyme. The distribution of the two enzymes in different muscle tissues has been investigated in two species and appears to correlate with muscle function.

Animals were killed by cooling to approximately  $-10^{\circ}\text{C}$ , the appropriate tissues dissected out and extracted by grinding with *N,N*-di(2-hydroxyethyl) glycine<sup>10</sup> buffer, pH 8.0 and 1.0.005 containing 0.3723 g of disodium EDTA and 0.3735 g of *N,N*-di(2-hydroxyethyl)glycine (bicine) titrated to pH 8.0 with concentrated sodium hydroxide free of carbon dioxide and made up to a final volume of 1 l. The cell debris was removed by centrifugation and the extract concentrated by vacuum dialysis against the same buffer. Molecular weight determinations of the arginine kinases were carried out on 'Sephadex G-100' as previously described<sup>1</sup> and enzyme activity in the fractions determined by assay for acid labile phosphate<sup>9</sup> after incubation with ATP, magnesium ions and arginine.

All the extracts were found to be without kinase activity towards creatine, glycoeyamine or taurocyamine. The distribution of the two types of arginine kinase in the muscles of several eulamellibranch molluscs is shown in

Table 1, which shows that both enzymes always occur in the adductor and siphon muscles of the animals investigated and occasionally in the foot as well. The concentrations of the two enzymes, however, vary considerably in the different tissues. The enzyme of molecular weight 40,000 predominates in the siphon; both enzymes occur in almost equal amounts in the adductor; the foot contains only the 80,000 molecular weight enzyme or in addition a trace of the 40,000 molecular weight enzyme. The relative proportions of the two enzymes in *Cardium edule* are shown in Fig. 1 and a similar distribution was obtained with *Tellina tenuis*. The proportions of the two enzymes were not affected by the presence or absence of EDTA or by lowering the pH of the buffer to 6.5, and the application of low concentrations of foot extract to the column did not result in the production of any 40,000 molecular weight enzyme. Hence there is no evidence that the 80,000 molecular weight enzyme is an artefact produced by association of two monomer enzyme molecules. Furthermore, it was found that the two enzyme types differed in stability; the 40,000 molecular weight enzyme was completely inactivated by storage for 2 months at  $-15^{\circ}\text{C}$  although the 80,000 molecular weight enzyme was scarcely affected. Activity of the monomer could be largely restored by treatment with 1 mmolar dithiothreitol (Cleland's reagent).

Table 1. DISTRIBUTION OF ARGININE KINASE ISOENZYMES AMONG SOME EULAMELLIBRANCH MOLLUSCS

Order and species	Muscle type	Arginine kinase	
		80,000 mol. wt.	40,000 mol. wt.
Heterodonta			
<i>Cardium edule</i>	Adductors	+	+
	Siphon	+	+
	Foot	+	—
<i>Tellina tenuis</i>	Adductors	+	+
	Siphon	+	+
	Foot	+	—
<i>Venus casina</i>	Foot	+	Trace
<i>Venerupis pullastra</i>	Adductors	+	+
<i>Laevocardium crassum</i>	Foot	+	Trace
Anapoda			
<i>Barnea parva</i>	Foot	+	Trace

Starch gel electrophoresis of muscle pooled from twenty animals (Fig. 2) revealed that only siphon and adductors contained the most electropositive component. This is assumed to correspond to the 40,000 molecular weight

Fig. 2. Starch gel electrophoresis of muscle extracts of *Cardium edule*. The positions of arginine kinase activity are shown by solid bars, slight activity is indicated by dotted area. A, Adductor muscle; S, siphon muscle; F, foot muscle. Extracts, buffers and the starch gel were prepared containing 1 mmolar Cleland's reagent to minimize the possibility of thiol oxidation artefacts.

enzyme and has a mobility similar to that of other known monomer arginine kinases<sup>9</sup>. The 80,000 molecular weight arginine kinase is represented by five or six components, possibly reflecting the allelic variants of one or two structural genes.

Although we have not been able to distinguish the vertebrate equivalent of smooth and striated muscle in these molluscs it is interesting to compare the distribution of enzyme type with muscle function. The siphon muscle has a principally tonic function—keeping the pair of siphons extended while the animal is active under water. The adductors have a tonic function, keeping the shell valves closed under adverse conditions, but are also capable of short fast phasic contractions to close the shell valves rapidly. The foot has almost exclusively short bursts of rapid activity for burrowing in mud or sand. The distribution of the monomer arginine kinase is associated with the tonic function similar to the smooth muscle in vertebrates while the 80,000 molecular weight enzyme is associated with the active "striated type" of muscle function.

Fig. 3. 'Sephadex G-100' column elution patterns of extracts of foot muscle of *Barnea parva*. —, Protein concentration measured at 253 m $\mu$ ; ○ — ○, arginine kinase activity; + · · · +, ATPase activity. The elution positions of standard proteins, rabbit creatine kinase (CK) and horse myoglobin (M), are marked as arrows.

This type of distribution would appear logical if the less highly organized smooth type of muscle evolved first and the more rapid type of muscle activity involving a dimeric arginine kinase was a relatively more recent evolutionary adaptation. This interpretation suggests that the arginine kinase is actually involved in the contractile machinery of the muscle. Evidence has been presented that creatine kinase binds to muscle myosin<sup>11</sup>, which supports this suggestion. We have found that variable amounts of arginine kinase sometimes appear just behind the break-through peak during 'Sephadex' chromatography if EDTA is omitted from the initial extraction medium. As is shown for *Barnea parva* (Fig. 3) this coincides with a peak of ATPase activity. No ATPase activity is found associated with the principal enzyme peaks. Czok and Bücher<sup>12</sup> reported that a medium containing EDTA was most efficient for extracting creatine kinase from rabbit muscle. It seems that arginine kinase behaves in a similar way and that in both cases metal ions mediate the binding of the enzyme to myosin. Because the myosin molecule is itself a dimeric molecule with two ATPase sites, the myosin-kinase interaction could be the selective advantage which has resulted in the evolution of a dimeric arginine kinase from a monomer enzyme as part of a more functionally efficient contractile mechanism. From studies of the kinases in other phyla<sup>1</sup> it is probable that this evolutionary event has occurred on more than one occasion.

## BIOLOGY

### Danger of Chlorinated Hydrocarbon Insecticides in Birds' Eggs

THERE has been considerable concern about the presence of chlorinated hydrocarbon insecticides in wild birds' eggs. The toxicology of chlorinated hydrocarbon insecticides has been evaluated<sup>1-3</sup>, using hens' eggs, and emphasis has usually been placed on the effects on hatching. In the experiments of Dunachie and Fletcher, hatchability was not affected even by very large doses (for example, 200 p.p.m. of dieldrin).

We have tried to evaluate the danger from these chemicals by measuring the concentration of dieldrin in the blood of embryos and in chicks hatching from eggs treated with this compound before incubation. Chlorinated hydrocarbon insecticides were injected into the yolk of White Leghorn eggs by the method of McLaughlin *et al.*<sup>4</sup>; all doses were given in 0.1 ml. of propylene glycol. In a first series of experiments, the dispersion of dieldrin in the yolk was measured at various intervals after injection. For this purpose each egg was dosed with 40  $\mu$ g of dieldrin. After each time interval the eggs were frozen at  $-15^{\circ}$  C for 1 or 2 days, after which the yolk was taken out and divided into segments while still frozen, as shown in Fig. 1. A central disk was cut out with a knife, and three circular segments were punched from the disk with a cork-borer (A, B and C in Fig. 1) which were analysed separately for dieldrin by gas liquid chromatography. Cleaning was by a dimethylformamide partition process<sup>5</sup>, followed by percolation of the extract over an activated 'Florisil' column. Indian ink was added as a marker to five of the eggs and showed that the top of the injection needle had entered segment A of each egg. The dis-

Fig. 1. Division of the yolk for the distribution study. A disk was cut from the frozen yolk with a knife (left side). Three circular segments were then punched from the disk with a cork-borer (right side).

Fig. 2. Concentrations of dieldrin in the blood in normally fed chicks which hatched from eggs treated with 240 µg of dieldrin before incubation (five chicks/value).

tribution of dieldrin in the three segments at different times after treatment is shown in Table 1. For comparison, similar analyses were made of an egg from a duck which had been treated with dieldrin and of two hens' eggs in which the natural DDE background was estimated. In addition, the yolk sac of one egg which had been incubated for 14 days was divided arbitrarily into three parts, and these were analysed separately. Equal concentrations were found, which indicates that during incubation the injected dieldrin (before incubation) is distributed throughout the yolk. Distribution is nearly complete after 5 days of incubation and from this time the injected eggs can be compared with eggs which received their dose of dieldrin from the birds which laid them.

In a second experiment, the concentration of dieldrin was measured in the yolk, blood and tissues of 14 day old embryos and chicks 0-6 h after hatching. Eggs were each dosed with 40 µg of dieldrin. For analysis of blood a rapid and accurate method, making use of gas liquid chromatography, devised by Richardson *et al.*<sup>9</sup>, was used. The method consists of extracting the blood sample with acetone by percolation over a column of silica gel and shaking the extract with an aqueous solution of sodium sulphate after the addition of 1-5 ml. of hexane to the acetone extract. From the hexane phase, samples can be applied directly to the gas chromatograph (Aerograph A-610-C). Embryonic blood was obtained from a blood vessel close to the egg membrane by means of heparinized capillaries of known volume. Chick blood was obtained by decapitation.

Table 2 shows that the concentration of dieldrin in the blood of the 0-6 h old chick is little greater than that in the 14 day old embryo, which indicates that the absorption process of the yolk sac during the last week of development does not cause an important increase in the concentration of dieldrin in the blood. The increase in the tissue concentration of dieldrin indicates that the dieldrin which is released from the yolk has been deposited in the tissues of the embryo.

Table 1. RELATIVE CONCENTRATION OF DIELDRIN IN THE THREE SEGMENTS FROM THE YOLK

	No. of eggs	Segment A	Segment B	Segment C
2 h after injection, eggs not incubated	2	100	2.8	0.4
120 h after injection, eggs not incubated	10	100	4.7	0.5
110 h after injection, eggs incubated	2	100	65.5	71.6
Egg of a duck treated with dieldrin	1	100	98.8	99.1
Normally occurring DDE background (0.14-0.17 p.p.m.)	2	100	103.0	99.7

The concentration segment A has been given the value 100. The averages for each group are given.

Table 2. DIELDRIN RESIDUES IN THE BLOOD, THE YOLK AND THE BODY OF EMBRYOS AND CHICKS DEVELOPING FROM EGGS WITH 40 µg OF DIELDRIN BEFORE INCUBATION

	No.	Dieldrin concentration In blood (µg/ml.)	In yolk (p.p.m.)	In whole animal minus yolk (p.p.m.)
14 day old embryo	10	0.028 ± 0.005	1.70 ± 0.27	0.11 ± 0.02
0-6 h chick	10	0.038 ± 0.006	1.44 ± 0.31	0.42 ± 0.16

Values are ± standard deviation.

In another experiment, the blood concentrations are measured in normally fed chicks during their first 5 days of life (Fig. 2). In this case each egg had been dosed before incubation with 240 µg of dieldrin. During the first 48 h after hatching the concentration of dieldrin in the blood increases considerably to a maximum of about 1.5 µg/ml. After the third day the concentration begins to decrease. At 120 h the initial concentration was reached again. Most bird species, including the chicken, do not eat during their first 24-48 h, and so absorption of the remaining yolk during this period obviously results in a strongly increased concentration in the blood. As soon as they start to eat and body weight increases, the blood concentration of dieldrin decreases. To test the effect of starvation beyond the first day, blood was taken from starved chicks at 0, 24, 48 and 72 h after hatching. Doses ranged from 240 to 960 µg to each egg. The results of this experiment are given in Fig. 3.

In these circumstances the concentration of dieldrin in the blood continues to increase after the second day. When a dose of 960 µg to each egg (about 17 p.p.m.) was given before incubation the chicks showed convulsions between 58 and 96 h after hatching. At that time a mean (critical) concentration in the blood of 11.5 µg/ml. ± 2.27 (S.D.) (fourteen chicks) was measured. Untreated chicks starved for the same length of time (or even 24 h longer) were in good health and readily started feeding afterwards. Fig. 4 shows a linear relation between the dose and the concentration of dieldrin in the blood in the 0 h chick.

We conclude that absorption of the yolk after hatching may cause poisoning of young birds by insecticides at a concentration of the residue which does not affect the rate of hatching. Our results explain the 100 per cent mortality immediately after hatching, observed by Dunachie and Fletcher in chicks which hatched from eggs

Fig. 3. Concentrations of dieldrin in the blood in starved chicks which hatched from eggs dosed with three different doses before incubation (5-14 chicks/value).

Fig. 4. The relation between blood concentration of dieldrin and dose for a chick at 0 h. Mean values and standard deviations are given (five chicks/value).

dosed with 100 p.p.m. of aldrin. These authors usually destroyed the chicks shortly after incubation. It may be assumed that several of the doses of the chlorinated hydrocarbon insecticides, which failed to produce any influence on hatchability or only caused a slight decrease in the rate of hatching, would have proved to be lethal if the chicks had been kept alive longer. In experiments of this kind it is therefore advisable, as McLaughlin mentioned<sup>4</sup>, to observe the chicks for a longer period after hatching. In trout fry mortality induced by DDT after absorption of the yolk sac has been reported<sup>6,7</sup>.

It is well known that in nature recently hatched birds are often deprived of food for long periods, for example, by unfavourable weather conditions. Their natural adaptation is the ability to live on the yolk for a few more days. The fast absorption of the yolk which follows may be hazardous when the birds have been exposed to toxic and persistent chemicals in the environment.

In 1965 we observed a large mortality among recently hatched sandwich terns in a colony in the Netherlands. The animals showed the same kind of convulsions as the chicks which hatched from the eggs dosed with 960 µg of dieldrin. Tissue analyses showed us that insecticides were the chief cause of death (Koeman *et al.*<sup>8</sup>) at that time.

We are grateful to Mr Richardson for discussion and advice on the method of blood analysis which was used. We also thank Professor C. Romijn, director of the Institute of Veterinary Physiology, for the use of the incubator and Mr D. van Dijk for his help. Eggs were supplied by the Zootechnical Institute of the University of Utrecht.

## Respiration of Air by the Primitive Fish *Polypterus senegalus*

THE primitive actinopterygian fish *Polypterus senegalus* Cuvier inhabits shallow and swampy waters throughout tropical Africa, often in conditions of severe oxygen deficiency, and its adaptation to this type of habitat includes the possession of spiracles and a double swim bladder or lung which has long been assumed to act as an accessory respiratory organ. Conflicting views have, however, been expressed regarding the use of spiracles in connexion with the respiration of air. Budgett<sup>1</sup> stated that the spiracles are used to take in and expire air from the swim bladders; but Boulenger<sup>2</sup> concluded that there was little evidence to show that *Polypterus* comes to the surface to breathe. More recently, it has been shown that the spiracles are used to inhale air which is passed to the lungs<sup>3</sup>. Air is inspired both in conditions of low oxygen concentration and during periods of excessive activity.

The investigation reported here has been carried out to obtain further information regarding the histology and physiology of aerial respiration in this species. Fish were injected with coloured rubber latex, and examination of the lungs revealed that they are highly vascular (Figs. 1 and 2). Transverse sections through the lungs showed an outer muscular coat of two layers of oblique and circular muscles, beneath which lies a thinner layer of loose connective tissue, containing branches from the pulmonary veins and arteries. The lungs are lined with a

highly vascular layer which is thrown into alveoli (Fig. 3). The epithelium of the lung is richly supplied with capillaries, among which are regular ciliated mucous bands running along the longitudinal axes of the lung (Fig. 4).

It therefore seems that the vascular lining of the lung cavity is involved in gaseous exchange. The ciliated bands secrete mucus which is distributed over the respiratory surface by ciliary action and assists in gaseous exchange. Both these features are characteristic of a respiratory epithelium. *Polypterus* makes use of its pulmonary respiratory mechanism when branchial respiration is insufficient to satisfy its oxygen requirements. Blood from the pulmonary arteries is oxygenated in the lung, if not already saturated on its passage through the gills.

### Serological Evidence for Speciation in the Grey Kangaroo, *Macropus giganteus* Shaw 1790 (Marsupialia : Macropodidae)

THE taxonomy of grey kangaroos (*Macropus giganteus* and "subspecies") is at present poorly understood; the number of species recognized by currently accepted authorities ranges from one<sup>1</sup> to four<sup>2</sup>. As part of a broad taxonomic study we collected the blood sera of 839 animals from more than forty localities throughout the range of the grey kangaroos and measured antigenic and electrophoretic variations in the serum proteins. We hoped to find differences, characteristic of particular groups of animals, which would correlate with geographical or taxonomic groups, and which might be useful in determining the degree of mixing and interbreeding between such groups. The details of these studies will be published elsewhere; here we wish to summarize the results as they relate to the problem of speciation in grey kangaroos.

Examination of all sera by starch-gel electrophoresis<sup>3</sup> revealed a polymorphism of the iron-binding protein (transferrin) similar to that demonstrated by Cooper and Sharman<sup>4</sup> in the red kangaroo, *Macropus rufus*. The hypothesis that this is a simple genetic polymorphism controlled by two co-dominant alleles allowing the production of three recognizable phenotypes is not contradicted by the considerable amount of data obtained by breeding grey kangaroos in enclosures at Canberra. All populations sampled in Western Australia, South Australia, Kangaroo Island and central New South Wales as well as a single individual from western Victoria, possess both alleles; all members of populations sampled in eastern Victoria, eastern and northern New South Wales and south-eastern Queensland, as well as a single individual from Tasmania, were found to be homozygous for *Tf<sup>A</sup>*, the allele controlling the production of the fast moving variant and its associated minor components. Thus two groups of populations can be distinguished on the basis of the presence or absence of one allele (*Tf<sup>B</sup>*) in this simple monogenic system. Because the observed characteristics of the serum proteins correlate with the geographical distribution of the populations, we refer to these groups as Eastern and Western.

The sera were also tested by double-diffusion<sup>5</sup>, using antisera produced in grey kangaroos by injecting members of the Eastern group with sera from individuals of the Western group, and vice versa. Injection of Western group animals with sera from other Western greys provoked no antibody response; we did not immunize Eastern greys with sera from other Eastern animals. The results of these tests showed that each group possesses characteristic antigens. The antisera react with two or more proteins, and we therefore assume that the antigenic differences between the two groups have a polygenic basis. Moreover, these differences have been shown to relate to different proteins from the transferrins.

While Eastern greys reacted only with antiserum against Eastern animals, and Western greys only with anti-Western sera, sera from five Eastern  $\times$  Western hybrids bred in captivity reacted with antisera against both Eastern and Western greys. One of these hybrids, a male, was backcrossed with an Eastern group female, and the serum of the resulting offspring reacted like that of an Eastern group animal.

Significant exceptions to the generalization that Western group grey kangaroo populations could be distinguished on the basis of the presence of *Tf<sup>B</sup>* were obtained from data derived from animals in two New South Wales populations which included greys possessing this allele. Three lines of evidence suggest that at Mt. Hope, central New South Wales, both kinds of greys were present but did not interbreed. (1) Of seventy-five animals from Mt. Hope most reacted serologically as Western group greys, but fourteen reacted like Eastern greys. None showed hybrid characteristics. (2) The fourteen Eastern greys

were also homozygous for *Tf*<sup>4</sup>. (3) Seven of the fourteen were pouch young. Although their mothers were not bled, their serological reactions and homozygosity suggest that these females were Eastern greys which bred with males of their own group.

Similarly, of forty-two animals taken at Balranald in the Riverina district of New South Wales, four were Eastern group with respect to antigens and were also homozygous for *Tf*<sup>4</sup>. One of these four was an adult male and the other three comprised a breeding female with her pouch young and one young-at-foot. Clearly this Eastern group female must have bred with Eastern group males in spite of her association with a predominantly Western group population.

Thus although it is possible with limited success to cross the two kinds of greys in captivity, our results suggest that hybridization does not occur in the field. The occurrence of sympatry without hybridization is good evidence for the existence of two species of grey kangaroos. Furthermore, other differences between the two kinds have been demonstrated. Thus gestation periods determined to date at Canberra are characteristic of each group: Eastern group has a mean gestation period of  $36.7 \pm 0.30$  days ( $n=10$ ); Western group,  $29.5 \pm 0.35$  days ( $n=20$ ); and the hybrid cross,  $34.4 \pm 0.16$  days ( $n=16$ ). In addition, the two species are distinguished by a difference in coat colour. Our records show that both colour morphs have been sympatric at Mt. Hope since observations of the population began in 1962, so that temporary or recent immigration of Eastern greys into the area cannot be the explanation for the observed lack of interbreeding.

Recently we were able to investigate the sera of eleven greys, kindly obtained for us by Mr G. Blackman (Queensland Department of Primary Industries) from the Townsville area, about 300 miles south of Cooktown, the type locality of *Macropus giganteus* Shaw 1790. These animals were all Eastern and similar in appearance to greys from Cooktown. Accordingly, consideration should be given to the application of the specific name *giganteus* to the Eastern species, including the Tasmanian grey kangaroo. The Western grey then becomes *Macropus fuliginosus* (Desmarest 1817) because the Kangaroo Island form was first named of this group of subspecies.

This work was carried out while one of us (J. A. W. K.) held, consecutively, a Fulbright Student Fellowship and a National Science Foundation Graduate Fellowship; in addition, it was supported by funds made available by the CSIRO and by the University of Western Australia Research Grants Committee. We thank Professor G. B. Sharman, Dr W. D. L. Ride and Mr John Calaby for their continued encouragement and advice.

### Multiple Budding on Carrot Embryos arising in Tissue Culture

STEWART *et al.*<sup>1</sup> reported the development in culture of carrot embryos which appeared normal and were able to continue development through all stages of the normal

carrot life cycle. Waris<sup>2</sup>, on the other hand, has reported that embryos from the seeds of *Oenanthe aquatica* L., in the presence of 0.1 per cent glycine, enter an abnormal developmental cycle in which nodules form on the embryo, then break off to form further embryos; most of the embryos were of abnormal structure. We have observed carrot embryoids of abnormal structure which were developed in tissue culture; they budded off other embryoids instead of continuing their development towards plantlets.

The carrot used was *Daucus carota* L., Carters 'Nantes Early Horn'. Sterile explants were taken from the storage root with a cork-borer. On a basal medium with 3 per cent sucrose, 15 per cent coconut milk, and 0.05 mg/l. 2,4-dichlorophenoxyacetic acid added, the tissue proliferated to form a callus which ranged in colour from orange to greenish yellow. One such culture was sub-cultured into eleven tubes of the same basal medium with the addition of 3 per cent sucrose, 1 g/l. yeast extract, 200 mg/l. casein hydrolysate, 0.5 mg/l. 1-naphthalene-acetic acid and 0.1 mg/l. of kinetin.

Three cultures produced only callus. Five cultures developed callus and roots, but in two of these the roots only appeared after more than three months. Three cultures developed embryoids in which the root development was absent or weak. True cotyledons were usually absent and there was instead a lobed leafy structure (Fig. 1). The further development of the embryoids consisted of swelling and budding off daughter embryoids. Fig. 2 shows such a rootless, mis-shapen embryoid with some buds.

The abnormal budding embryos of Waris seem to have been occasioned by the amino-acid imbalance in his culture medium and it is possible that, in our experiments, the casein hydrolysate and yeast extract may also have introduced an amino-acid imbalance, responsible for the

Fig. 1. ( $\times 8$ .)

Fig. 2. ( $\times 8$ .)

budding. The observations thus provide a link between the formation of embryoids in culture and multiple budding. The variability of the response most probably reflects the heterogeneous nature of the original explants.

## PHYSIOLOGY

### Inversion of the Fahraeus-Lindqvist Phenomenon in Blood Flow through Capillaries of Diminishing Radius

THE flow of blood in the microcirculation is of great physiological and clinical importance but, because of its complexity, the mechanism is not fully understood. Fahraeus and Lindqvist<sup>1</sup> first observed an apparent decrease of blood viscosity when it flowed through capillaries of decreasing diameters. Their work was later confirmed<sup>2-6</sup> and the reality of the Fahraeus-Lindqvist phenomenon was accepted. Its explanation, often attempted<sup>2,7-9</sup>, relied chiefly on the concepts of an axial concentration of red cells and/or on the effect of a plasmatic "lubricating" layer along the capillary walls.

Nearly all investigations, however, were carried out at capillary diameters considerably greater than  $100\mu$ , within the normal range of haematocrits. I have considered two problems: (a) whether the Fahraeus-Lindqvist phenomenon is true for a range of capillary diameters nearer to the physiological ranges observed in microcirculation; and (b) whether it is true at high haematocrits. The Fahraeus-Lindqvist phenomenon is shown to occur with capillary radii of as little as  $5\mu$ , but this phenomenon is reversed and the apparent blood viscosity increases with a further decrease in the capillary radius.

To facilitate investigation in capillaries of radii as small as  $2.5\mu$ , while retaining manageable flow times, capillary viscometers of the U-type were constructed with the usual cylindrical capillary replaced by a slit formed by two parallel glass plates. The plates were 0.75-1 in. thick and polished to optical flatness, the tolerance being few wavelengths of light only. Plates were separated by means of thin polythene strips greased with silicone grease, and clamped together by 2 in. "cramps" (Fig. 1). The glass plates used were of different sizes, depending on the radius (half-gap) required. Large slits were formed by plates  $18 \times 8$  cm, while small slits were formed by plates  $3 \times 21$  cm.

Samples of blood were obtained from human donors or from giant Queensland toads and amphiumas ("Congo eels"). Blood samples from human donors were obtained by venipuncture and collected in plastic bags containing acid citrate dextrose. Blood from toads was obtained by insertion of a needle into the aorta of the toad after the thorax was opened. Blood from a dozen toads was required for a single experiment. Amphiumas were about 3 ft. long and weighed 500-550 g. The chest was incised and, after location of the aorta, blood was collected and anticoagulated in the usual way. Haematocrit determinations were made by means of a microhaematocrit Hawksley centrifuge. Platelets were removed by repeated centrifugation and by siphoning off of the buffy coat. Blood was examined in a plastic capillary under the microscope to check for aggregation of platelets.

Platelet aggregates can clog large capillaries (larger than  $100\mu$ ) and so great care was taken to eliminate them; only siliconized equipment was used. Nevertheless, plate-

let aggregates were found in some blood samples, and such samples were discarded.

Blood pH was checked with a 'Radiometer pH-Meter'. Microcapillary slit-viscometers were calibrated using distilled water delivered through a syringe equipped with a 'Millipore' filter. All viscosity data are given as viscosity relative to water.

An effect of the capillary radius (half-gap) on the relative viscosity of human blood at 49 per cent haematocrit, toad blood at 49.5 per cent and 95 per cent haematocrits, and amphiuma blood at 29 per cent haematocrit, is illustrated by Figs. 2 and 3. Viscosity was tested at pressure gradients of 10 and 20 cm of water/cm of length of capillary.

Blood viscosity decreased as the radius of the capillary decreased, down to  $6-7\mu$ , and thus the Fahraeus-Lindqvist phenomenon is clearly present. There is, however, a sharp increase in the viscosity of both blood and packed cells when the radius of the capillary decreases to less than  $5\mu$ .

It should be clearly stated here that the red cells of humans are the smallest (about  $85\mu^3$ ), the toads' cells having about ten times more corpuscular volume, while the red cells of amphiuma are relative giants of more than  $11,000\mu^3$ . The latter cells are flat ellipsoids measuring (mean)  $68.6 \times 42.5\mu$ . It is therefore interesting to see that the behaviour of these cells, of such different dimensions, is remarkably similar.

Figs. 4 and 5 show that the reversal of the pattern of flow is not caused by a permanent clogging but by the rheological properties of blood. It can be seen that flow depends on the pressure gradient, and that even at very low pressure gradients such flow continues. Tests carried out earlier by means of the rotational viscometers<sup>10,11</sup> show that this effect is caused by the rheology of the cell interior.

From these results I draw the following tentative conclusions. (a) The Fahraeus-Lindqvist phenomenon can

Fig. 1. A diagrammatic representation of a parallel-plate (slit) microcapillary viscometer. 1, Glass plates; 2, pipettes; 3, polythene tubing leading from pipettes to the 2 mm bore channels in the glass plates; 4, arterial clips used to clamp polythene tubing joined on the left side of the glass plates. The shaded area on the glass plates corresponds to the polythene seals and demarcates the outline of the capillary proper. The direction of flow is from the top pipette, through the slit-capillary, to the lower pipette. Tubing closed by arterial clamps is filled with the same blood sample, but is inactive during the actual operation of viscometer; it is used to facilitate cleaning of instrument.

be seen in blood of humans, toads and amphiumas in slit capillaries for a range of capillary radii; (b) the phenomenon can be seen in the packed red cells of haematocrits up to 98 per cent; (c) the critical radius, at which a transition from the Fahraeus-Lindqvist pattern to an inverse pattern (inverse phenomenon) takes place, lies between 5 and  $7\mu$  in the conditions of my investigation and in the absence of platelet aggregates; (d) the critical radius is probably not affected by haematocrit; and (e) the critical radius will be greatly affected by the presence of platelet aggregates, and this phenomenon could be caused by the greater internal viscosity of the platelets than the red cells.

This work was supported by the National Heart Foundation of Australia.

*Note added in proof.* Recent experiments indicate that the tonicity of saline, and the temperature, might also affect the critical radius. In the packed human red cells

Fig. 2. The Fahraeus-Lindqvist phenomenon and the inverse phenomenon in blood of humans and toads. Viscosity of blood, relative to water, is plotted against the capillary radius (half-gap) in  $\mu$ . Viscosity is given on a logarithmic scale. Pressure gradients of 5, 10, and 20 cm of water/cm of length of capillary were used. Numbers along the curves indicate the nominal shear rate at the wall, in reciprocal seconds.  $T$  = Temperature.

Fig. 3. The Fahraeus-Lindqvist phenomenon and the inverse phenomenon in blood of toads and amphiuma. Viscosity, relative to water, is given on a logarithmic scale and plotted against the capillary radius (half-gap) in  $\mu$ . The dotted line (open circles) indicates a probable, if speculative, outline for the true position of the curve.  $T$  = Temperature.

Fig. 4. Viscosity-pressure curves for human and amphiuma blood used in tests illustrated by Fig. 3. Viscosity, relative to water, is plotted against the pressure gradient in cm of water/cm of length of capillary. The top left experimental point, indicated by an arrow, corresponds to  $\eta_r = 2,000$ .  $H$ , Haematocrit;  $R$ , radius of capillary in  $\mu$ .

Fig. 5. Pressure-flow curves for packed toad red cells. Volume,  $Q$ , in ml/sec, is plotted against the pressure gradient,  $P$ , in cm of water/cm of length of capillary.  $H$ , Haematocrit;  $R$ , radius in  $\mu$ . The curves obtained curve gently towards zero.

(in the absence of platelet aggregates) of haematocrit of 84 per cent and tonicity of 80 per cent, the critical radius was found to be  $10\mu$  when tested at  $37^\circ\text{C}$  and  $16\mu$  when tested at  $20^\circ\text{C}$ ; under the isotonic conditions, the same red cells (at the same haematocrit) showed the critical radius of  $6\mu$  at  $20^\circ\text{C}$  and  $4\mu$  at  $37^\circ\text{C}$ .

## BOOK REVIEWS

## CHEMICALS FROM OIL

## The Petroleum Chemicals Industry

By Richard Frank Goldstein and A. Lawrence Waddams. Third, revised and enlarged edition. (Spon's General and Industrial Chemistry Series.) Pp. xiv + 523. (London: E. and F. N. Spon, Ltd., 1967.) 120s. net.

THE transformations of the hydrocarbons contained in petroleum and natural gas are now the main processes in the chemical industry, in so far as carbon compounds are concerned. Whilst animal and vegetable natural products, such as the fats and waxes, are still important, and coal is still more so, yet the trend to the oil source is unmistakable. Mineral oil, already in a dominant position, is conquering more and more territory at an accelerating rate of progress. A surprising example of this is the extent to which the newer plants for the production of town and industrial gas are based on oil rather than on coal.

A petrochemicals factory has a general aspect similar to that of a petroleum refinery; a conglomeration of tall, relatively narrow towers, pipes, and boilers. The reason is that the operations are similar; petroleum refining involves tailoring the crude oil by fractionation, treatments by heat alone, or over catalysts and by use of physical methods of separation. A number of chemical changes are brought about by synthesis or degradation.

The marvellous alchemy of petrochemical productions approaches nearer and nearer the ideal simplicity cum complexity of the refinery. As progress is made, more and more of the processes can be operated continuously on a very large scale, and apart from catalysts the chemicals introduced are only air and water. Temperature and pressure are the chief variables.

As one illustration, among many possible, phenol (carbolic acid) used to be made (probably still is made in some localities) from coal-tar benzene (benzole) by reaction with sulphuric acid followed by treatment of the product with caustic soda and isolation after dilution with water and acidification. All this involved considerable handling. Nowadays, there are two processes dependent on oxidation of hydrocarbons, available from petroleum. They are summarized as: benzene + propylene → isopropylbenzene, which +  $O_2$  → hydroperoxide → phenol + acetone, and toluene by oxidation → benzoic acid → copper salt, and by oxidation → phenol.

The earlier editions of this book have gained an enviable reputation as the best available account of the processes used in the petrochemicals industry, and this new and considerably revised and augmented edition will be esteemed still more highly. In fact, it can safely be claimed to be the most complete and authoritative general account of the subject that is anywhere available.

The coverage extends to early 1966 and hence a number of quite new topics have been introduced. In addition, the older material has been carefully sifted and many new developments have been noted, and yet, by careful attention to what is really essential, the size of the book has been kept within such limits that it may be read with pleasure and not used exclusively as a work of reference. On the other hand, it does function successfully in this latter capacity and will be frequently consulted, especially by technologists and planners.

The fundamental basis of the book is a description of the chemistry of processes used in the industry and of the

conditions in which they may be carried out. The chemical engineering involved is not treated except for some very general implications; a few flow-diagrams are included. A chapter on chemical by-products from petroleum refining lies a little outside those based on the main chemical classification, and so does another dealing with economics and statistics.

This book, because it illuminates a whole, relatively new field of chemistry, should be studied by advanced students and research workers in universities. It will be found indispensable to those actually working in the petrochemicals industry.

R. ROBINSON

## INTRODUCING LUNAR GEOLOGY

## The Craters of the Moon

An Observational Approach. By Patrick Moore and Peter J. Cattermole. Pp. 160 + 16 plates. (London: Lutterworth Press, 1967.) 35s. net.

THIS book presents the results of the interpretation, by an astronomer and a geologist, of observations of the lunar surface. It is the latest addition to the discordant serious literature in this field, for the authors conclude that virtually all features of the surface result from endogenic processes. This is not too surprising; since Baldwin, in his book *The Face of the Moon*, established both the modern form of the impact theory of lunar surface formation and the current wave of controversy, interest in this problem has been growing, and the importance of internal activity is at last being widely recognized by all lunar specialists. The essentially new suggestion here is that the origin, as well as the subsequent shaping, of most of the surface features is caused by volcanic activity.

After a brief enumeration of the main types of surface feature the authors give a historical summary of the theories of crater origin. In order to justify their view that internal processes predominate they summarize, in the next two chapters, the geological principles and types of terrestrial volcanic structure to which they need to refer; here it is, perhaps, a pity that references to standard texts on geological principles are not more in evidence.

Turning again to the Moon, a short chapter is devoted to an interesting discussion of processes neither volcanic nor meteoritic which have been advanced to explain various features. There follows a concerted and well planned attack on the weak points of the impact theory, together with a discussion of the development of volcanic theories which lead the authors to the conclusion that no violent processes can be involved for the formation of the larger lunar features, and that some kind of relatively gentle internal activity must be postulated. This idea is justified by the comparison of selected lunar features with corresponding terrestrial ones, and good analogies are found in most cases, an exception being that of the "bowl" craters; here the authors prefer to think in vague terms of "... a type of vulcanism rather different from any that we have encountered on Earth", rather than attribute these craters to any other source.

Next, an indication of the lunar surface materials that may be present assuming volcanic processes is given; here also more references might usefully have been given to sources of information on the techniques of investigating the lunar surface by measuring its physical properties from the Earth.

After a consideration of the possibility that there is still some activity on the surface, the now less controversial subjects of lunar tectonics, deformations and the grid system are presented; this part of the book also describes the particular properties of the mare floors and mountainous regions. A chapter on the ray systems deals first with the inconsistencies of impact theories and then

suggests a mechanism involving the development of small craters along lines of weakness. Finally, the main conclusions are summarized.

The authors leave the reader in no doubt as to the bias of their views, and in fairness it must be stressed that, if the most important references given are consulted (for example, those given at the end of Chapter six), a fair cross section of opinion will be encountered. Despite the specific points mentioned here, in general the book is very well documented, particularly as it deals with so many individual types of feature. It represents a readable and wide ranging introduction to this field for both the amateur astronomer interested in the interpretation of observations and the scientist wishing to get up to date with lunar geology.

L. WILSON

## VACCINE, WITH CARE

### The Hazards of Immunization

(Based on University of London Heath Clark Lectures, 1966.) By Graham Wilson. Pp. x+324. (London: The Athlone Press, University of London, 1967. Distributed by Constable and Co. Ltd.) 45s. net.

THERE are few who have the depth of knowledge or even the courage to attempt to present the hazards of immunization. Many of the data have appeared over a long period in many journals and reports, but to assemble these facts in an interesting, balanced, and unbiased account is most difficult. Sir Graham Wilson has succeeded in his task and the medical world is the richer for this book based on four Heath Clark lectures given at the University of London in November 1966.

The hazards have been divided into (a) accidents occurring during production and administration of the vaccines and (b) complications arising in the vaccinees.

The accidents are concerned mainly in association with new prophylactics and they are dealt with in seven chapters on faulty production. Of the accidents considered under the title "Inherent Toxicity", by far the greatest number have occurred as a result of inadequate toxoiding of toxin, or the use of toxin-antitoxin mixtures now considered to be dangerous and discontinued. Also considered under this heading are the failures to kill pathogenic viruses and the use of a living virus inadequately attenuated. The conclusions drawn from the findings of the accident enquiries are of great value, and it is interesting to note that, weight for weight, man is at least as susceptible as a guinea-pig to diphtheria toxin. Equally important is the observation that diphtheria toxin must remain in tissues for a long time, where it may not be neutralized by antitoxins, and late symptoms may develop. Examples are given of the appearance of a foreign toxin in an antitoxin, the use of an incorrect culture for vaccine production, and the contamination of the final product with both bacteria and viruses. It is some comfort, however, to know that such accidents occurred before the modern methods of production and control became effective.

Having dealt with the production of vaccines, Sir Graham considers the accidents that occur during reconstitution and administration. These largely result from the use of contaminated equipment, much of which is eliminated by the use of sterile packed and disposable apparatus. In spite of all these modern developments, however, as recently as 1966 local abscesses caused by *Streptococcus pyogenes* type 12 occurred in one clinic after giving sterile DTP vaccine. The same streptococcus was isolated from the nose and throat of the doctor and nurse attending the clinic as well as from the scissors used to open the sterile packs.

Allergic manifestations occurring in the vaccinees are a much more difficult problem and no fewer than seven chapters are devoted to this aspect. Local allergy, serum sickness, encephalomyelitis, neuroparalysis and general

anaphylaxis occurring after the administration of prophylactics are all mentioned. The abnormal sensitivity of the patient has not been overlooked and skin complications of smallpox vaccine, local or generalized tuberculosis, occurring after BCG or vole bacillus vaccines or tuberculin, as well as complex reactions to other vaccines, are recorded.

Sir Graham has been particularly careful to draw attention to the potential dangers of all vaccination procedures and to put them in their right perspective. In this respect the dangers associated with immunization, using both established and new vaccines, are discussed and the need for continuous surveillance is emphasized.

There is no doubt that all physicians will wish to read this book, which should also find a place in the permanent records of all libraries. It is a unique collection of data superbly assembled.

F. T. PERKINS

## CANCER PREVENTION

### Prevention of Cancer—Pointers from Epidemiology

By Richard Doll. (The Rock Carling Fellowship, 1967.) Pp. 143. (London: The Nuffield Provincial Hospitals Trust, 1967.) 7s. 6d. net.

SINCE the first investigation by Hirsch in 1883, much information has been accumulating about the distribution of cancer in human communities in different geographical areas and with different occupations. From the information which we have already, maps can be constructed to show the relative incidence of a particular type of cancer; a map in this book illustrates clearly that cancer of the oesophagus is about two hundred times more frequent in the northern regions of the Caspian than in Holland; another shows a gradient in the incidence of stomach cancer, high in Russia, decreasing in Europe, the eastern states of the USA, but rising again in the western regions.

The subject of cancer epidemiology is the study of the relationship between the environment and the incidence of the disease. The task is not to establish only a relationship between cause and effect, but to test by various methods whether the relationship is a true one, and whether the suspected agent is directly or indirectly implicated in the causation of cancer. Can statistical evidence alone be acceptable as definite proof of a cause-effect relationship; and how far can the experimental data obtained in animals be extrapolated to man? These problems are discussed with great objectivity in the book being reviewed. Dr Doll, besides putting forward definite conclusions, draws attention to the difficulties which may arise in collecting and analysing relevant information and describes some of the pitfalls of epidemiological studies. Dr Doll is one of those to whom we owe the critical application of epidemiological principles to the incidence of leukaemia and lung cancer—revealing some causes of both of these malignant diseases. Because of his experience and scientific knowledge he is particularly well suited to argue the value of studies which concern the possible relationship between cancer incidence and environmental agents. Some of these agents (radiation, cigarette smoking, asbestos, benzene,  $\beta$ -naphthylamine) and the way by which information relating to them has been evaluated are well described. Attention has been paid to the often voiced question: why does one person develop cancer while another exposed to the same environmental hazard escapes such a fate? Is there a genetically determined susceptibility? Doll examines the evidence available from twin studies and states that in the aetiology of common types of cancer the environment is more important than the genetic component.

Doll's book merits serious consideration by all who are concerned with cancer and human well-being. According to him almost 40 per cent of cancer deaths in men and 10 per cent in women can be prevented because we know the cause. We are still ignorant of the cellular mechanism which transforms a normal cell into a cancer cell,

and no effective measure can be devised to reverse the process, so that our chance of reducing the incidence of cancer lies in removing the agent from the environment which causes it. Epidemiological studies spotlight some of these agents, and no doubt more could be identified if information was available.

Doll puts in a plea for a record-linkage system which, by covering the whole community, could provide the needed information to reveal other carcinogenic agents which then could be removed from man's environment. Doll's excellent book should be read by those, in government or industry, who have the power to act.

P. C. KOLLER

## LIVELY EMBRYOS

### Éléments d'Embryologie Causale

By J. Fautrez. (Collection d'Enseignement Biologique.) Pp. 302. (Paris: Gauthier-Villars, 1967.) 32 francs.

To many students of biology and medicine embryology means the growth and development of boredom. Microscope slides showing sections at different "levels" of particular "stages" of selected "types" are drawn, labelled and forgotten. A few plastic models and a pickled foetus or two may be thrown in for good measure, and then teacher and students alike pass with relief to something else.

Professor Fautrez gets right away from this atmosphere. He writes in a clear and lively style, and from start to finish his embryos live. He assumes that the reader knows some elementary general biology, including the rudiments of embryo anatomy, and sets out to introduce him to causal embryology. The overall plan of the book follows the conventional sequence, beginning with the gametes and fertilization, and ending with the development and co-ordination of the main organ systems. But always Fautrez asks why each embryonic structure should develop where and when it does, and how it is that the embryo is able to survive each phase of its development long enough to grow into the next.

Particularly attractive is his use of experimental evidence. The book is not intended to be an advanced treatise, and although sufficient experiments are quoted to keep the reader in touch with the excitements and frustrations of embryological research, the main argument is never swamped with experimental detail. On some topics the experimental evidence appears conclusive, but where there is uncertainty or conflict the rival theories are carefully explained. There is a nice mixture of examples from recent and older work and from a wide range of animal species. Obviously a book of this size cannot include all the experimental evidence that is relevant, and there must be an element of arbitrariness in the choice that is made; but Fautrez's aim has been to write a good book on embryology, not to administer divine justice to embryologists, and he has been admirably successful.

The deficiencies of the book are small compared with its merits. It is adequately illustrated with photographs and diagrams which, with one or two exceptions, are clear and informative; but it might have been helpful if the reader were referred to them in the text instead of being left to stumble on them by accident. The chapter on embryonic membranes is disappointing; it gives a poor idea of the intense activity of these remarkable structures and contains several misleading statements, for example that the cleidoic eggs of vertebrates are surrounded by an "impermeable" shell. There is also a curious omission from the chapters on gametogenesis of any mention of chiasmata formation and crossing-over; it is implied that the only important function of the second meiotic division is to halve the amount of DNA.

It is unfortunate that the language barrier will restrict the number of English-speaking students who can make use of this book. But it can be strongly recommended to students of all ages who either read French easily or who wish to improve painlessly both their biology and their French.

D. A. T. NEW

## KEEPING UP WITH PHYSIOLOGY

### Annual Review of Physiology

Vol. 29. Edited by Victor E. Hall in association with Arthur C. Giese and Ralph R. Sonnenschein. Pp. vii + 652. (Palo Alto, California: Annual Reviews, Inc., 1967.) \$8.50.

THERE are a number of ways in which the physiologist can keep abreast of the ever increasing volume of literature which according to MEDLARS amounts to some 120,000 papers in medicine and allied sciences each year. The conventional abstracting and indexing services are useful for obtaining information about specific topics, but for a more general coverage recourse may be had to *Physiological Reviews*, which covers a small number of subjects in great depth, and the *Annual Review of Physiology*, which gives a broad coverage.

The twenty-ninth volume of the *Annual Review of Physiology* covers the literature up to May 1966 in a wide field of physiology. Information about the nervous system occupies about a third of the volume and covers growth and differentiation of nerve cells, electrophysiology of the cell, afferent mechanisms, higher functions, hearing, vision in *Limulus* and a welcome review of motor mechanisms. Cardiovascular, respiratory and endocrine physiology (adenohypophysis, reproduction, parathyroid and calcitonin) are well represented. For the general physiologist there is much of interest about transport through biological membranes, metabolism, and invertebrate excretory organs. Gastric physiologists will be happy with the review of gastric secretion, and a chapter on lymphatics and lymphoid tissue contains useful information about the thymus and antibody responses.

The ability of the physiologist with special interests to obtain a list of relevant literature without difficulty raises the question as to the type of reader this annual review is now designed to interest. For the specialist there is no alternative but to read the literature himself. The ideal readers would presumably be teachers of physiology who, devoting their interests to special topics, may have difficulty in keeping themselves generally informed. For such readers this annual review can only be of interest if clear ideas of the advances and problems are obtained. This need is met by a number of articles in which the authors have deliberately limited the scope of their review. The articles by Gaze on growth and differentiation, Bernstein on respiration, Guillemin on the adenohypophysis, Arnaud, Tenenhouse and Rasmussen on parathyroid, and Wolbarsht and Yeandle on visual processes in *Limulus* are particularly clear and critical. These reviewers have added interest to their articles by referring to the authors of important papers by names rather than by a series of reference numbers.

On the other hand, a number of authors introduce their reviews by apologizing for their inability to cover the entire accumulation of literature in their specific field. They certainly cover an enormous amount and the thorough way in which the literature has been collected and subdivided can only lead to admiration. Such reviews, while being useful, are a non-critical compilation of the literature. It is difficult for a reviewer to be critical of work in a subject allied to his own but outside his immediate interests.

The scope of the reviews has been of concern to the editors who saw the first flicker of the publication

explosion when the first volume was produced in 1939. The preface to this volume advised authors "to attempt a critical appraisal of the contemporary field". The present editorial policy of further restricting the coverage of any field should lead to a better description of recent work. There seems little point, anyway, in reviewing a field in which there has been no significant advance. The problem seems to be defined by R. V. Short in his entirely enjoyable review on reproduction. He mentions that the *Bibliography of Reproduction* lists 10,000 articles, of which he is aware of 5 per cent and influenced by about 1 per cent. With the use of 195 references he gives the reader an outstanding account of reproductive physiology. If more chapters were written in this vein it may be that the *Annual Review of Physiology* would find its way into more personal libraries in addition to university libraries, where it still justly remains one of the pillars of the physiological establishment.

D. MENDEL

## QUANTUM MERUIT

### Vision and the Eye

By M. H. Pirenne. Second edition. Pp. xvi + 224 + 16 plates. (London: Chapman and Hall, Ltd., 1967.) 50s. net.

ONE of the enchanting aspects of the polymorphous subject of vision is that it can accommodate both the cantabrian crank and the oxonian omnivore. Dr Pirenne's far-flung interests, his erudition, and profound understanding, all characteristic of the latter species, have made him singularly suitable for the authorship of this academic treatise. And by "academic" I wish to convey the original notion of the word as depicted by Raphael in the Vatican. We are led from pin-hole camera photography (in connexion with which Fig. 1.15 needs some thought to grasp it) to the splendid illusions of baroque turmoil; from the eyes of insects to the anatomy of the brain; from some unpublished experiments due to Hartline to the directional properties of the retina. Dr Pirenne's vigorous analytical approach, followed, it should be noted, practically without any algebra at all, will be familiar to the readers of the first edition. The chapter on the nervous response to light is somewhat extended in comparison with its antecedent and concentrates on the properties of the lateral eye of the horseshoe crab. While there are people who might wish for details of recordings obtained from the eyes of higher vertebrates, if not primates, a great deal is to be said for the grasshopper's approach, which subsists in sampling tit-bits in various places.

Yet puzzles remain. There is no hint in this finely produced book why the Stiles-Crawford effect, "which cannot be described here" (last edition, page 11), can now be described. The section on binocular vision makes no mention of one of the most dramatic discoveries in the whole of this subject, namely the demonstration by Julesz that contours may arise from stereopsis rather than, as Helmholtz contended, that the contrary should be true. While Dr Pirenne wisely refrains from a discussion of the relation between visual pigment regeneration and the time-course of adaptation to darkness, his faith in some results bearing on the alchemy of human colour vision is simply endearing. But the principal puzzle relates to the inordinately large number of pages reserved for the role that the quantum and probability play in vision. The demonstration of this role is due in no small measure to the experimental work done twenty-six years ago by Pirenne in conjunction with Hecht and Shlaer. That this important contribution has received its due desert is also attributable to Dr Pirenne's many writings on the subject. Does he believe that any one in his right mind could ever challenge the basis of the experiments? Then why omit important new material and repeat the story with the detail which was necessary in 1948 but seems redundant in 1967?

Perhaps only those who have shouted in the wilderness know the answer; maybe only those whose shouts have been in vain will understand.

R. A. WEALE

## AFRICAN FISHES

### Freshwater Fishes of Southern Africa

By R. A. Jubb. Pp. vii + 248 + 57 plates. (Cape Town and Amsterdam: A. A. Balkema, 1967.) R. 12.50.

MR JUBB aims at a wide audience, in particular the naturalist, the angler and the fishery biologist. They are well served by this, the first book of its kind to give comprehensive coverage to the freshwater fishes of southern Africa, taken in this context to be that vast area stretching from the Zambezi and Cunene rivers in the north to the multitude of smaller rivers in the Cape Province of South Africa.

Although not strictly a taxonomic revision (the author, too modestly, calls it a "pictorial guide"), this book is clearly based on many years of detailed and critical systematic research, backed by much fieldwork and consequently a first-hand knowledge of the fishes' ecology. Thus *Freshwater Fishes of Southern Africa* is bound to find a place also on the professional ichthyologist's bench.

The text is divided into four principal parts, of which the longest is the systematic section dealing with the 157 indigenous species of southern Africa. With few exceptions, there is for each species a description and figure (usually a photograph, but sometimes a coloured drawing as well). The brief specific description gives live coloration and diagnostic anatomical characters distinguishing the fish from related species in the area. Distributional data, vernacular names, remarks on feeding habits and other ecological information, and often short accounts of intra-specific variability in diagnostic characters are also included.

Here I must compliment the author's wife, Hilda Jubb, on the excellent figures which she has prepared. Most of these are skilfully retouched photographs in which, without creating any imbalance or obscurity, she has emphasized the main diagnostic characters and yet retained the essential character of the fish as a whole. Opinions differ on the value of photographs as illustrations for taxonomic papers (I for one favour line-drawings); Mrs Jubb's expertise has certainly reduced my opposition, and amply justified the use of photographs in a work of this nature. In addition, Mrs Jubb has added to the value and aesthetic appeal of the book by providing more than fifty original coloured drawings.

Because the illustrations are a vital part of this work (especially in its role as a pictorial guide for amateurs) it is regrettable that there is often poor spatial correspondence between text and relevant figure. This arrangement is the more regrettable because most users of the book will have wet or dirty fingers, and the illustrations can only be found by leafing through the pages, because no figure reference is given with the species description.

Following the section on indigenous fishes there is a shorter but equally comprehensive one on introduced exotic freshwater fishes, and native euryhaline species found in fresh waters. The introduced species (all of European or north American origin) are carefully documented from the historical as well as from the ecological and distributional points of view.

A semi-pictorial key serves as an introduction to both systematic sections. This key is simple to use, and avoids the common pitfalls of many "popular" keys because of the author's skilful avoidance of too finely divided dichotomies. Instead, the user is led, in most cases, to a group of similar species and must then refer to the fuller descriptions to make his final identification. Frequent use of simple outline drawings further helps to prevent the novice from straying far down the wrong branches.

The key ends a series of wide-ranging introductory chapters. In these Mr Jubb discusses, among others, such diverse topics as fossil fishes in southern Africa, the physiological and hydrobiological characteristics and history of the region, and the classification of fishes. There is also an introduction to fish anatomy with particular reference to characters used in the systematic section. Some of these chapters are much better than others; the main faults stem from the inevitable compression needed if so many different fields are to be covered at all. I believe that Mr Jubb made the right decision in attempting this task. Too often the general reader is left in ignorance of the complex historical and environmental factors that have influenced, and still influence, the fishes which are his prime interest.

A map with the main rivers of southern Africa clearly labelled would be of great value to the reader unfamiliar with the country (the map provided shows only the most important drainage basins and is inadequate for detailed work), but the situation is alleviated by the excellent gazetteer of principal river systems (would that more authors should follow this practice). I would also criticize some of the imprecise definitions and minor inaccuracies in the anatomical section, particularly because these slips are likely to mislead the non-zoologist. For example, the circumorbital bones of a tigerfish are labelled "operculum" (Fig. 8), the premaxilla is labelled "maxillary" (Fig. 26), and the figure showing tooth-bearing bones in the jaws is rather imprecise. It must be emphasized, however, that these are but slight and easily rectified imperfections in an otherwise detailed and simply written guide to a complex subject.

Also included in the introductory section is an annotated check-list of southern African freshwater fishes. Synonymies are included, and so is information on the distribution of species (including indigenous species transferred into drainage basins to which they were not endemic). More detailed distribution lists are provided in a separate series of tables dealing with each of the main drainage systems. Taken together, these various analyses form an extremely valuable and unique compilation of data otherwise scattered through many sources, some now inaccurate and outdated.

The fourth, and final, section of the book deals with fishing methods, fish farming, angling, and the use of certain species in home aquaria and garden ponds. Much of this material is beyond my competence, but I would draw attention to the subsection on primitive fishing methods. Here, Mr Jubb has brought together much historical material and several unique photographs, all of which serve to illustrate and record a rapidly vanishing aspect of African culture. Taking his subject even further back in time, Mr Jubb also reviews the few but fascinating and somewhat enigmatic rock paintings from South Africa in which fishing scenes are depicted.

*Freshwater Fishes of Southern Africa* is a valuable contribution to the literature on African fishes, and its appearance will be welcomed by professional and amateur naturalists in many fields. Its place in the permanent literature of southern African natural history is assured; but, if future editions are to have the wide and popular use that the author's efforts and high standards so richly deserve, the publishers will have to bring down the price to a more realistic level.

P. H. GREENWOOD

## SOME PROTEIN TECHNIQUES

### Techniques in Protein Chemistry

By J. Leggett Bailey. Second, revised and expanded edition. Pp. xiv + 406. (Amsterdam, London and New York: Elsevier Publishing Company, 1967.) 110s.

THE mere fact that so specialized a book as this has required reprinting after two years and a second edition

after five demonstrates clearly, by the hard test of sales, that it is of real value. There can be no doubt that the second edition will be just as useful and successful as the first.

The title of the book is a little misleading because it is not by any means an account of all the techniques used in protein chemistry. It is, rather, a detailed account of a selection of these techniques, notably those employing chromatographic procedures and useful for sequence studies on proteins. The first three chapters deal with the chromatographic and electrophoretic separation of amino-acids and peptides and the next four with methods used for sequence determination in proteins. There is then a chapter on dialysis and gel filtration (surely a rather ill-assorted pair), followed by two chapters on the column chromatography and zone electrophoresis of proteins. A short chapter on miscellaneous analytical methods is followed by a chapter, added in this edition, on the synthesis of simple peptides. I doubt whether this last chapter, good though it is, is of real relevance to the theme of the book; biochemists might well find it best to persuade their organic chemist colleagues to undertake any such syntheses for them.

The revision carried out for this second edition has been very thorough. About one-third of the thousand or so literature references are to papers published since 1960; very few relate to papers published since 1964. The book itself, despite pruning of older material, has also been expanded by about one third. There is, however, still some duplication and some further pruning might have been carried out with advantage; thus, for example, nearly all protein chemists nowadays use automatic amino-acid analysers and much of the third chapter seems irrelevant to current practice.

The book is well and clearly written. I found few errors, but there is a misleading one on page 23 ("nitrate" for "nitrite") and something has gone very wrong with the equations for the Akabori hydrazinolysis reaction (page 226).

These shortcomings are relatively minor blemishes on an excellent book. This is a work of real character and it is clear from every page that the author really knows what he is talking about. In his preface he hopes that the book will be "something handy to have in the laboratory"; it is much more than this, being an essential tool for everyone working in, or even only on the fringes of, the field of protein sequences. We shall all be looking for a third edition in a few years.

H. N. RYDON

## ACETYLENE COMES INTO ITS OWN

### Acetylene

Its Properties, Manufacture and Uses. Vol. 2. By S. A. Miller. Pp. xvii + 406. (London: Ernest Benn, Ltd., 1966.) 126s. net.

THE appearance of the second volume of Dr Miller's work has been eagerly awaited. Not surprisingly, the large amount of chemistry to be covered has been found to necessitate a third volume and the present part covers only simple addition across the triple bond, leading largely to the industrially important vinyl compounds and halogen derivatives. Deferred until later are all reactions in which acetylene is used as a "building block" in organic synthesis, that is, ethynylation reactions, linear and cyclic polymerizations and carbonylation.

Since the first volume, debate about the relative merits of the old giant, acetylene, compared with ethylene as the optimum starting material for large tonnage chemical intermediates has continued. Some plans to use acetylene have been changed to the use of other feedstocks, but a number of manufacturers decided to opt for naphtha based acetylene processes, sometimes to replace carbide in order to continue to use existing equipment for often

simple and certainly well-tried further chemistry. Gloomy stories circulate as a result—and it is abundantly clear that what acetylene wants is a hydrocarbon based production process that works as designed within the capital sanctioned. If this can be achieved, developments towards Dr Miller's hope, expressed in an entertaining and spirited preface, of acetylene at 3d./lb. might be possible. While acetylene's troubles are being sorted out, however, ethylene production by naphtha cracking continues to expand on an ever-increasing scale and 0.5 million tons/yr units are now being made. The odds are that ethylene will reach 2d./lb. long before acetylene reaches 3d. and the old giant will still have fallen, entirely as Dr Miller suggests, through hard economics, the most lethal sickness of all.

Apart from the basis of the chemicals dealt with in this book and the processes leading to them, a substantial part is devoted to the chemistry of the initial products, and this is, and will remain, extremely valuable. The author is clearly well informed and the book is a mine of information and obviously the result of a lot of very hard work.

The first chapter deals comprehensively with hydrogenation and halogenation. The former is important not because anyone would want to make ethylene from acetylene today, but because acetylene is a contaminant in ethylene made by naphtha cracking and selective hydrogenation to ethylene is one way of removing it. Actually, as crackers grow to the 0.5 million tons/yr scale and beyond, it becomes economically possible to recover the acetylene as such from the ethylene. Such an operation would, however, require an amendment to the Explosives Act of 1875, which hitherto has forbidden the bottling of acetylene which has at any time in its history, irrespective of proportion in any mixture, been under a pressure of more than 22 lb./in.<sup>2</sup> gauge. Ethylene is commonly distilled at about 250–300 lb./in.<sup>2</sup> pressure, and so there has been a distinct lack of flexibility about what can be done with the product. A recent Home Office draft order could make the technically possible legally possible. Some relaxation of the antediluvian regulations surrounding acetylene has been clearly needed for many years; they are or were an obvious institutional barrier hindering technological progress in the UK in marked contrast to the situation in America and Western Germany.

Halogenation is covered admirably in the book. Trichloroethylene and its chief use, metal degreasing, is extensively dealt with; yet there are signs that some authorities, especially in America, are unhappy about its toxicological properties. Possibly later editions will require considerable expansion of the section on the up and coming methylchloroform, which is less toxic than trichloroethylene and finds application in, for example, cold degreasing. Room might also be found for the more exotic trifluorodichloroethane used in degreasing of electronic parts.

A whole chapter deals comprehensively with hydrohalogenation, chiefly the production, properties and polymerization of vinyl chloride and the properties of the polymer. The bibliography of this section is particularly good.

The third chapter on acetaldehyde and acrylonitrile is from the production point of view strictly historical. Again, the properties and reactions part is thorough and well done.

Vinyl ethers receive a whole chapter and the current situation is well covered and documented. Unfortunately, the price of these materials militates against their use and little progress can be expected until some new cost breakthrough is achieved.

Vinyl esters, and particularly vinyl acetate, are fully described. Interest is at a maximum, because in this area acetylene has most promise as a continuing starting material, especially if it is coupled with the cheap acetic

acid from naphtha oxidation. Several ethylene based processes to vinyl acetate are now being developed, but the degree of sophistication in the oxidation step is likely to be at a maximum, whereas the acetylene route is conversely relatively simple. The whole chapter is very informative, although copolymers certainly merit more than a page. Thus, on pages 288 and 289, the 'Elvax' type of vinyl acetate-ethylene copolymers, which are (like ICI Alkathene VIG 501, etc.) modified polyethylenes, are lumped together indiscriminately with the emulsion copolymers like 'Aircoflex' which contain only minor amounts of ethylene. The two types of product are quite different in composition, process of polymerization and end uses. Some 80 per cent of the emulsions made in the UK, USA and Germany are copolymers and their introduction has considerably expanded the field of usefulness of this type of material. The recent commissioning of a 20,000 tons/yr of vinyl "versatate" plant by Shell underlines the importance of these "other" vinyl esters, all of which are indisputably acetylene derivatives.

The final chapter deals with "other vinylation"; curiously vinylation on sulphur (in the contents list) of nitrogen and on carbon, silicon and tin. Vinyl carbazole and vinyl pyrrolidone, the two main products of interest from Reppe's pioneering work in this field, are dealt with in detail.

This is an admirable book and I look forward to the third volume. As usual, it is beautifully produced, which adds to the enjoyment of reading it. H. W. B. REED

## DRUGS AND THE BRAIN

### Pharmacology and Physiology of the Reticular Formation

Edited by A. V. Valdmán. (Progress in Brain Research, Vol. 20.) Pp. viii + 339. (Amsterdam, London and New York: Elsevier Publishing Company, 1967.) 125s.

THIS book is a collection of papers, each dealing with a specific aspect of research on the central nervous system. The authors are all research workers in the department of pharmacology at the University of Leningrad, and so it is really an up to date account of the research in that department. In that respect it represents a sequel to the two previous volumes mentioned in the preface and published respectively in 1958 and 1961. It would, however, be incorrect to give the impression that the authors refer only to their own work or to Russian publications. The world literature is extensively reviewed and there are thirty-six pages of references at the end of the text, although not many references are to papers published after 1960, which is surprising in a book published in 1967.

The book is edited by A. V. Valdmán, who is also the author of the first chapter on the "Pharmacology of the Brain" and co-author in three other contributions. This first chapter in fact comprises almost one-third of the text and is probably the most important part of the book. It is an extensive review of the state of knowledge of the actions of drugs on the central nervous system up to 1960. For example, the actions of narcotics on electrophysiological phenomena, ranging from the electrocorticogram and sensory-evoked potentials to the activity of single neurones, are discussed. There is an extensive account of the actions of analgesics, particularly morphine, and it is suggested that the analgesic action of this substance may be related to an interference with the balance of noradrenaline metabolism. Other topics treated in this chapter are sympathomimetic drugs, tranquillizers, cholinergic drugs and stimulants.

Other chapters deal with effects of drugs on behavioural responses to electrical stimulation of the hypothalamus, a detailed description of some anatomical aspects of the reticular formation, and contributions to pharmacological analyses of the pontine respiratory and vasomotor centres.

A chapter on synaptic transmission by A. I. Shapovalov is largely devoted to a consideration of events at the neuromuscular junction, although acetylcholine does not appear until the seventh page. The work of Katz, Eccles, Koelle and others is discussed in some detail. Similarly, the chapter on central inhibition is largely devoted to a discussion of the ideas of Eccles and his associates.

One might think that a chapter on the pharmacology of smooth muscle would be out of place in a book with this title, but, coming where it does, it is not inappropriate.

The book makes interesting reading, but it is more suitable for the expert in this field rather than students. Even so, those who are not familiar with Russian drug names may find themselves lost from time to time.

P. B. BRADLEY

## OBITUARIES

### A. A. Lombard

ADRIAN LOMBARD, who died on July 13, had been the director of engineering of Rolls-Royce, Ltd., since 1958. In this position he had full responsibility for the design, development and supporting research on all the company's aero engines. When he became chief engineer at the age of 39 he was, in fact, only the third man in the history of the company to take on these responsibilities, his predecessors being Mr A. G. Elliott and Sir Henry Royce. Like them, he had worked on the design of motor cars, having started his engineering career with the Rover Company. He was in the small design team that worked on the Whittle jet engine, which Rover started to develop in 1940, and he continued as chief designer when Rolls-Royce took over the Rover work in 1943. From then onwards he was directly involved with a continuing line of Rolls-Royce jet engines, including the pure jet Derwent, Nene and Avon; the turbo-prop Clyde and Tyne; the Conway, which was the first by-pass engine in production, and the Spey by-pass engines; a family of vertical take-off engines and others still under development.

Lom, as he was called throughout the industry, was a dedicated man with the single-minded purpose that the engines his company produced should be the best in the world. He would never accept second place. He drove his large team of well qualified men by example, enthusiasm, humour, sometimes sarcasm and always a sheer disbelief that improvement was impossible. He enjoyed argument—on specific cases rather than general issues—and had a phenomenal memory which enabled him to discomfort any opponent who had changed his ground since the last encounter. His own academic qualifications were slight, but he was intensely interested in any scientific work that affected a design and with an intuition uninhibited by preconceived theories could always make a penetrating comment or novel suggestion in any discussion. At the same time he was a firm believer in the absolute necessity for a far sighted programme of research on problems related to the gas turbine, particularly on the materials side, and insisted on adequate resources being provided for it. In fact, whenever a new idea came up, such as the air cooling of turbine blades in the early days of the gas turbine or more recently the use of carbon fibre reinforcement of plastics, he personally followed the progress of its development right through to the production stage.

Lombard's work did not end at home with jet engine design. He went around the world selling the engines on their technical merits and feeding back the requirements of the operators to his own team. In this dual role he had continually to make that most difficult of all design compromises, the balance between a performance that is easily achieved but not attractive to the user and that

which is extremely attractive but unachievable in an economic time scale. His subordinates were continually dismayed by the promises that he had made abroad on their behalf, but his determination ensured that those promises were finally honoured. As a result of his wide travelling and of the many important lectures he delivered to aeronautical and engineering societies in a number of countries, he was internationally recognized and honoured, being appointed C.B.E. this year and receiving the James Clayton prize of the Institution of Mechanical Engineers jointly with Dr S. G. Hooker.

The application of science to technological progress owes much to men of Lombard's calibre: it is sad there are so few of them.

S. L. B.

### Dr A. W. Gledhill

DR ALAN W. GLEDHILL died suddenly on July 19, 1967, while attending an international veterinary congress in Paris; he was 57. He was born at Southend-on-Sea and was educated at Bedford School and Trinity College, Cambridge, where he studied mathematics. On choosing a career in veterinary medicine, he studied further at the Royal (Dick) Veterinary College, Edinburgh, and the Royal Veterinary College in London. From 1935 to 1939 he served as veterinary officer in Uganda, being particularly concerned with the control of epizootic diseases.

He returned to Britain in 1939 to work with F. Blake-more at the Institute of Animal Pathology in Cambridge. Here he was concerned with one of the first isolations of swine influenza virus in Britain. His main interest, however, was in *Erysipelothrix rhusiopathiae*, the bacterium causing swine erysipelas, and his interest continued after he left Cambridge. He made important contributions to knowledge of its antigenic constitution and the application of this knowledge to production of a vaccine.

In 1947 he was appointed veterinary officer to the National Institute for Medical Research, Mill Hill, in succession to R. E. Glover. He co-operated with the team working there in WHO's World Influenza Centre. In 1951 came a discovery which affected all his subsequent work. Infant mice in the breeding stock at Mill Hill were dying of a hepatitis which was apparently due to a hitherto unknown virus. Unexpectedly, however, its activity could be inhibited by tetracyclines. It was shown that its effects were due to the synergistic action of two agents, one stable, one more labile, each relatively harmless by itself. The labile agent proved to be the blood-parasite, *Eperythrozoon coccoides*, and it was this which was susceptible to antibiotics. In much of this work Gledhill co-operated with Dr J. S. F. Niven, Dr G. W. A. Dick and myself.

These discoveries initiated a series of studies on non-specific factors affecting susceptibility and resistance. A number of agents were examined for their mutual enhancing or sparing activity: bacterial endotoxins, *Eperythrozoon*, tuberculosis and the viruses of mouse hepatitis, infectious ectromelia, mouse leukaemia and lymphocytic choriomeningitis. The results were complex; much depended on timing and dosage.

All this work had a bearing on latent infections, particularly in mice, and the confusing effect of these for laboratory workers. Gledhill was accordingly keenly interested in the possibility of maintaining stocks of "specific-pathogen-free" animals. He had been appointed head of an Animal Division at the National Institute for Medical Research and was particularly concerned in planning accommodation for laboratory animals which would ensure a supply of really clean stock.

Gledhill was an attractive colleague with an original mind, always enthusiastic, never happier than when wrestling with a problem complex enough to deter all but a really devoted seeker after truth.

C. H. ANDREWES

## University News:

London

THE title of professor of naval architecture has been conferred on Mr L. J. Rydill in respect of his post at University College.

Salford

THE university and the Shirley Institute are planning to undertake co-operative research projects which will be both of good academic research character and also provide results of direct significance to technical and industrial processes. One of the first projects selected deals with the use of high-energy irradiation to initiate grafting of polymers on to fibres, films and fabrics.

## Appointments

THE Hon. J. J. Astor has been appointed chairman of the Agricultural Research Council in succession to the Duke of Northumberland, who is to relinquish the position on June 30, 1968.

## Announcements

THE current list of reprints available from the Ministry of Technology's Forest Products Research Laboratory has now been published and is available on request from the Director, Forest Products Research Laboratory, Princes Risborough, Aylesbury, Bucks.

**CORRIGENDUM.** In the article "Surface Topography of Ice Sheets" by G. de Q. Robin, which appears on page 1029 of this issue of *Nature*, the first symbol of equation 2 on page 1030 should be the Greek letter rho and not alpha.

# CORRESPONDENCE

## Computers for Scientific Research

SIR,—During the past few years a revolution has occurred in the pattern of spending needed to support basic scientific research. In practically every scientific field, as in technology and business, computers have now become a necessity without which it is often impossible to keep in the front line. It is my purpose to point out that there is evidence of a serious failure by the British Government to provide adequate funds to keep up with this revolution and to suggest that a major revision of policy on expenditure on scientific research is needed in order to build up the computing power needed in all branches of scientific research.

Minimum expenditure on computers for scientific research in this country recommended for the current year by the Flowers committee was about £4.5 million, with a further £1 million for installation and running costs. This was expected to rise to a total of about £8 million by 1969. This sort of money has to be scaled against a total budget for all fields of research provided through the Department of Education and Science to the research councils and the University Grants Committee of about £100 million in the current year.

Unfortunately, even before the computer investment programme recommended by the Flowers committee was initiated, the rate of investment in computing facilities was cut back to a total of £3 million a year for the first three years (1966–69). Moreover, the implementation of this reduced programme of spending was severely delayed despite the emphasis of the Flowers committee report on the need to make up for the very late start in Britain in

getting under way on investment in computers for basic scientific research. There is no doubt that this cut-back and delay on the minimum rate of investment in computers is bound to have serious repercussions on progress in Britain in practically every field of scientific research.

It is instructive to contrast the Government's investment policy on this very basic and essential general research facility with the policy on investment in the largest single item, in a sense a luxury item, in our scientific budget: high energy nuclear physics. Britain is spending £12 million on high energy physics in the current year. And there are signs that there will be strong pressures to increase this. For instance, the mammoth high energy machine recently proposed for CERN will cost in the region of £150 million, of which Britain's share would be in the region of £33 million (see also *Nature*, 214, 1283; 1967). The contrast between investment in computers and that in high energy physics is the more striking in that an increasing proportion of the high energy physics budget is being spent on providing computing facilities exclusively for high energy physics research. An example of this is the recent purchase by the Science Research Council of two large (by British standards) American computers, one sited in Oxford and one in London, specifically for the purpose of processing data from high energy physics experiments. These computers, at a cost of £0.25 million each, are each more powerful (though with slightly less peripheral equipment) than most of the computers at present serving the needs of entire universities in Britain (if they are lucky enough to have one at all). For instance, the University of Sussex was only able to spend about half the cost of one of these computers on the computer they recently installed to serve the needs of the entire university.

One of the problems facing scientists in other fields is that they have no direct way of applying pressure for support for computing needs. High energy physics, on the other hand, by the very nature of the large funds already committed to it, is in a strong position to get still further support for its computing needs: if you are spending £12 million a year to gather data, then it is eminently reasonable to spend a further £0.5 million to process some of it. But the frustration of scientists starved of computer access who see thousands of pounds worth of computer time going unused during the development period of these specialized computer experiments is not to be under-estimated. The expenditure of these large sums when essential needs are being under-supported should not be allowed to continue without question.

What is to be done about this? The high energy physics lobby is very well organized. Individual computer users are not. As presently organized, university computer policy is organized from on high, and computer time is simply handed out when available. One possibility might be to make all computer users pay for computer time with money awarded to them in the form of research contracts as is the practice in the United States. This would both encourage economy and enable individual users to put pressure on the Government directly on the basis of the merits of their research proposals. It would also allow individual scientists to go to commercial companies for facilities, such as on line programming, which are not at present provided by university computer services.

Whatever happens, it is vital that the training of our scientists and the morale of research workers in all fields of basic research should not be undermined through an unwillingness to change established patterns of research spending. Britain's future depends on our ability to face the computer age fairly and squarely.

Yours sincerely,

S. DONIACH

Department of Physics,  
Imperial College,  
London.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Sunday, September 3—Wednesday, September 6

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE (at Leeds)—Continuation of 129th Annual Meeting.

## Sunday, September 3

At 10.30 a.m.—OFFICIAL SERVICE IN LEEDS PARISH CHURCH. Preacher: The Most Reverend and Right Honourable F. D. Coggan, P.C., D.D., Lord Archbishop of York.

## Monday, September 4

At 10 a.m.—Dame Kathleen Lonsdale, F.R.S.: "Physics and Ageing" (Presidential Address, Section A).

At 10 a.m.—Mr N. L. Falcon, F.R.S.: "The Geology of the North-East Margin of the Arabian Shield" (Presidential Address, Section C).

At 10 a.m.—Dr A. T. Lucas: "Felling and Napping in Early Ireland" (Presidential Address, Section H).

At 11.30 a.m.—Dr D. E. Broadbent: "Aspects of Human Decision Making" (Presidential Address, Section J).

At 11.30 a.m.—Prof. T. A. Bennet-Clark, C.B.E., F.R.S.: "The Role of Plant Sciences in the Modern World" (Presidential Address, Section K).

At 2.30 p.m.—Dr B. J. Mason, F.R.S.: "Thunderstorms and Lightning" (Young People's Lecture).

At 8 p.m.—Mr D. R. Pilbeam: "Human Origins" (Evening Discourse).

## Tuesday, September 5

At 11.30 a.m.—Dr J. A. Gray: "The Physiological Basis of Personality" (Lister Lecture).

At 2.30 p.m.—Prof. C. S. Whewell: "The World of Fibres" (Young People's Lecture).

## Friday, September 8

BRITISH SOCIETY OF AUDIOLOGY (at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 5 p.m.—Inaugural Meeting. Dr J. D. Hood: Inaugural Address. Dr I. C. Whitfield: "Centrifugal Control of Threshold Responses to Auditory Stimuli at the Level of the Cochlear Nucleus"; Mr A. Boothroyd: "Developments in Speech Audiometry".\*

INSTITUTE OF MATHEMATICS AND ITS APPLICATIONS (at the (proposed) University of Dundee—Tower Building, Dundee), at 10.15 a.m.—Symposium on "Some Recent Applications of Pure Mathematics". Speakers: Mr N. Lawrie, Dr A. Page and Dr R. Delbourgo.\*

## Sunday, September 10—Tuesday, September 12

BOTANICAL SOCIETY OF THE BRITISH ISLES, in association with the LINNEAN SOCIETY OF LONDON (at the Hartley Botanical Laboratories, the University of Liverpool)—Conference on "Modern Methods in Plant Taxonomy".

## Monday, September 11

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr R. C. Teasel and Mr R. D. Miller: "Characteristics of New Ignition Systems to Improve Engine Performance".

## Monday, September 11—Friday, September 15

INSTITUTION OF MECHANICAL ENGINEERS, APPLIED MECHANICS GROUP (at Imperial College of Science and Technology, London, S.W.7)—Conference on "High Pressure Engineering".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

RESEARCH ASSISTANT to direct a research unit working on human colonic physiology in conjunction with surgical staff—The House Governor, The London Hospital, Whitechapel, London, E.1 (September 9).

RESEARCH ASSISTANT (with the degree of B.Sc. (Ordinary) or an H.N.C. (Chemistry) in the DEPARTMENT OF CHEMISTRY to join a team engaged in co-polymerization studies under Dr G. G. Cameron—The Secretary, The University, Aberdeen (September 11).

LECTURER or ASSISTANT LECTURER in SOCIAL STATISTICS in the DEPARTMENT OF SOCIOLOGY, SOCIAL STUDIES AND ECONOMICS—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (September 12).

DEMONSTRATOR or SENIOR DEMONSTRATOR in the DEPARTMENT OF PURE MATHEMATICS—The Registrar, The University, Liverpool, quoting Ref. RV/158 (September 15).

JUNIOR RESEARCH FELLOW (with a good honours degree in physics and research interests in solid state physics) in PHYSICS—The Registrar, The University, Sheffield (September 15).

SENIOR LECTURER in BIOCHEMISTRY; a SENIOR LECTURER/LECTURER in ENGINEERING; a SENIOR LECTURER in MATHEMATICS; a LECTURER in GEOLOGY; a LECTURER in GEOGRAPHY, and a LECTURER in PSYCHOLOGY at the University College of Townsville, University of Queensland—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 22).

LECTURER (with research interests in the field of cell biology or embryology and preferably some proficiency in biochemical techniques) in ZOOLOGY in

St. Salvator's College—The Secretary, University of St. Andrews, College Gate, St. Andrews, Fife, Scotland (September 23).

RESEARCH FELLOW in ORGANIC CHEMISTRY to join a group working on the chemistry of orthoquinones—Professor J. M. Tedder, Chemistry Department, The University, Dundee, Scotland (September 23).

RESEARCH ASSISTANTS (with experience in electronics, experimental psychology, electro-physiology, or computer techniques) in the DEPARTMENT OF COMMUNICATION for a programme of basic research into perceptual and communication problems of the blind and deaf—The Registrar (N), The University, Keele, Staffordshire (September 25).

ASSISTANT LECTURER or LECTURER in CHEMISTRY (the appointment may be made in any branch of physical chemistry)—The Registrar, The University, Sheffield (September 30).

LECTURERS/ASSISTANT LECTURERS (3) in CIVIL ENGINEERING at the University of Hong Kong—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Hong Kong and London, September 30).

RESEARCH FELLOW (M.B., Ch.B., or B.Sc. with honours in pharmacology, physiology or biochemistry) to join a group engaged in research on the mode of action of narcotic analgesic drugs—Dr H. W. Kosterlitz, Marischal College, The University, Aberdeen (September 30).

SENIOR LECTURERS or LECTURERS (with qualifications in either pure or applied mathematics) in MATHEMATICS at the University of Canterbury, Christchurch, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 9).

PROFESSORIAL FELLOW, SENIOR FELLOW, FELLOW, SENIOR RESEARCH FELLOW and a RESEARCH FELLOW in the DEPARTMENT OF ASTRONOMY, Institute of Advanced Studies, Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 20).

ENTOMOLOGIST (with a good honours degree in zoology with special emphasis on entomology and an interest in and aptitude for taxonomic research) for work on hymenoptera in the COMMONWEALTH INSTITUTE OF ENTOMOLOGY identification service at the British Museum (Natural History)—The Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, near Slough, Bucks (October 31).

SENIOR LECTURER (medically qualified with a higher degree in pathology and experience in teaching and routine diagnostic work) in the DEPARTMENT OF PATHOLOGY (Austin Hospital), University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 31).

GEOCHEMIST (with evidence of research ability at the postgraduate level) in the CHEMISTRY DIVISION, DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH, Lower Hutt, New Zealand, to join a group doing research on the geochemistry of natural hydrothermal systems in New Zealand—The High Commissioner for New Zealand, New Zealand House, Haymarket, London, S.W.1, quoting Ref. B 13/15/57/2543 (November 30).

JOHN INNES CHAIR OF GENETICS; and JOHN INNES CHAIR OF APPLIED GENETICS at the School of Biological Sciences and John Innes Institute—The Registrar, University of East Anglia, Earlham Hall, Norwich, NOR. 88C (November 30).

ASSISTANT PROFESSOR or ASSOCIATE PROFESSOR (interested in cardiovascular pharmacology or biochemical pharmacology) in the DEPARTMENT OF PHARMACOLOGY—Professor G. B. Frank, Department of Pharmacology, University of Alberta, Edmonton, Alberta, Canada.

CHEMIST or BIOCHEMIST (graduate) to co-operate in a research programme to study the physical characteristics and mechanism of action of insulin—The Registrar, University of York, Heslington, York.

GRADUATE ASSISTANT in CHEMISTRY to work under the direction of Dr S. T. Reid on the synthesis of heterocyclic compounds of potential biological interest—The Registrar, The University, Canterbury, Kent, quoting Ref. A73.

J. R. MCKENZIE RESEARCH FELLOW (preferably Ph.D. or M.Sc. with experience in the lipid carbohydrate metabolic field) in BIOCHEMISTRY at the Wellington Hospital Medical Unit, New Zealand, undertaking clinical research in the lipid field and major epidemiological cardiovascular surveys among Polynesians in the Pacific and New Zealand in 1968–69—Professor W. J. H. Butterfield, Department of Medicine, Guy's Hospital, London, S.E.1.

LECTURER (with good academic qualifications and capable of supervising research students for the Ph.D. degree) in CHEMICAL ENGINEERING—The Registrar, University of Salford, Salford 5, quoting Ref. CE/3.

LECTURERS in GEOGRAPHY at the University College of Rhodesia—The Inter-University Council, 33 Bedford Place, London, W.C.1.

PHYSICIST or CHEMICAL ENGINEER (with a first- or upper-second-class honours degree in physics or the equivalent, and preferably some experience of research in the application of physical methods to the properties of materials, especially foods) in the BIOENGINEERING SECTION, to work as a member of a team concerned with technological problems in improving the efficiency and output of the British meat industry—The Secretary, Meat Research Institute, Agricultural Research Council, Langford, near Bristol, Somerset, quoting Ref. BMI.

POSTDOCTORAL RESEARCH BIOCHEMIST to study the effect of anti-inflammatory drugs on protein and nucleic acid biosynthesis—Professor M. J. H. Smith, Department of Biochemical Pharmacology, King's College Hospital Medical School, London, S.E.5.

POSTDOCTORAL RESEARCH WORKER to work in association with Dr R. A. Beatty on problems of animal gamete genetics—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh, 8.

RESEARCH ASSISTANT (science graduate preferably with experience in cytogenetics) in CYTOGENETICS—Professor W. Davidson, King's College Hospital, Denmark Hill, London, S.E.5.

RESEARCH FELLOW (with a Ph.D. degree or equivalent research experience) at the University College of Townsville to undertake full-time research on the structure and metabolism of polysaccharides of tropical pasture legumes—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; and The Warden, University College of Townsville, P.O. Box 999, Townsville, Queensland, Australia.

TEACHING FELLOWS in the FACULTY OF SCIENCE, University of Otago, Dunedin, New Zealand—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1, or the Registrar, University of Otago.

TECHNICIAN or JUNIOR TECHNICIAN in the BIOCHEMISTRY DEPARTMENT—The Staff Officer, University of Surrey, Battersea Park Road, London, S.W.11.

TECHNICIAN (preferably with previous experience) in the DEPARTMENT OF OBSTETRICS and GYNACOLOGY for research work in cytology—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1, quoting Ref. ASC/1158.

## HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one or two copies of NATURE each week is:

### \*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire.....	£14.0.0 each
United States of America.....(by air freight).....	\$44 each
Canada.....(by air freight).....	\$47.80 each
Elsewhere overseas by surface mail.....	£13.15.0 each
(Charge for delivery by air mail on application)	
*Shorter periods <i>pro rata</i> . (Minimum three months.)	

### MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

#### 12 MONTHS (52 issues and 4 indexes)

Number of Copies	G.B. & Eire	U.S.A.	Canada	Elsewhere
		(by air freight)	(by air freight)	(surface mail)
3-5	Each £13.10.0	Each \$42	Each \$46.00	Each £13.10.0
6-11	£12.15.0	\$40	\$43.60	£12.15.0
12 or more	£12.0.0	\$38	\$41.70	£12.0.0

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)

## The Properties of Liquid and Solid Helium

J. WILKS

This volume presents an extensive and critical survey of the physical properties of condensed  $^3\text{He}$  and  $^4\text{He}$ . Particular attention is also given to the wide variety of experimental techniques employed in the study of helium at low temperatures. 3 plates, 365 text figures £7 10s net

*International Series of Monographs on Physics*

## The Organic Chemistry of Nitrogen

N. V. SIDGWICK

*Revised and Rewritten by* IAN T. MILLAR *and* H. D. SPRINGALL

In this new edition of a classic of chemistry, emphasis has been placed on compounds, their structures, transformations, and the mechanisms of their reactions, with appropriate explanation of the necessary physical background. *Third edition, frontispiece, numerous text figures* £8 8s net

## The Genera of Flowering Plants (Angiospermae)

Based Principally on the *Genera Plantarum* of G. Bentham and J. D. Hooker

DICOTYLEDONES: VOLUME II

J. HUTCHINSON

The second of ten projected volumes designed to provide keys to and descriptions of all known genera of flowering plants. £9 10s net

## Infra-Red Physics

J. T. HOUGHTON *and* S. D. SMITH

'... for the student just beginning infra-red research this should be compulsory reading. It is by far the best comprehensive book produced to date in this field and forms a valuable addition to the spectroscopic literature.' *Proceedings of the Physical Society* 135 text figures 60s net

## A Manual of CAPSTAN

*Computer Analysis of Projects*

This book deals with the network technique and critical path method as used in computer processing. It should be of interest to those in production engineering, civil engineering, contracting, and the building industry.

19 text figures, paper covers 15s net

*Harwell Post-graduate Series*

## The Memory System of the Brain

J. Z. YOUNG

'It is easy to foresee that the work on the Octopus brain will for generations to come mark one of the most important milestones on the road of our understanding of brain function. There are comprehensive references and a good index.' *Institute of Biology Journal* 32 text figures 28s net

## An Introduction to Magneto-Fluid Mechanics

V. C. A. FERRARO *and* C. Plumpton

'The authors intend it to be an introduction for research workers in magneto-hydrodynamics and plasma physics. ... They succeed admirably ... the paperback version could be recommended as a "best buy" for a new student.' *Nature* *Second edition, 2 plates, numerous text figures* 50s net (paper covers 25s net)

## Ultrasonic Absorption

*An Introduction to the Theory of Sound Absorption and Dispersion in Gases, Liquids, and Solids*

A. B. BHATIA

This book should be useful to graduate students and research workers who wish to know the basic theoretical ideas and experiments in this field. 1 plate, numerous text figures 85s net

*Monographs on the Physics and Chemistry of Materials*

OXFORD  
UNIVERSITY PRESS

**Classified Advertisements**

Semi-displayed £4 16s. per single column inch. Minimum £2, each additional 1/12th of an inch 8s. Full page £132. Half page across £66. Colour (orange) £15 extra. 1s. is charged for the re-direction of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, Strand, London, W.C.2. Telephone: 01-405 4743. Telegrams: Textualist, London, W.C.2.

**APPOINTMENTS VACANT**
**UNIVERSITY OF LIVERPOOL**  
 DEPARTMENT OF INORGANIC,  
 PHYSICAL AND INDUSTRIAL  
 CHEMISTRY

Applications are invited for an S.R.C. Post-doctoral Research Fellowship for work on reactions of methylene (CH<sub>2</sub>) and imidogen (NH) radicals, with particular reference to their photoformation and reactions in condensed and gaseous phases, with Professor C. H. Bamford. The initial salary will be £1,125 per annum, together with F.S.S.U. benefits, where appropriate. Commencing date to be arranged mutually.

Applications, with a curriculum vitae, and the names of two referees, to be sent as soon as possible, to the Registrar, The University, Liverpool 3. Please quote ref.: RV/153/N. (722)

**PRODUCTION CHEMIST. EXPERIENCED** in fine organic chemical manufacture required by expanding company in Central London. Please give full particulars of qualifications, experience, etc., in confidence to Box 933, Nature, T. G. Scott & Son Ltd., 1 Clements Inn, London, W.C.2. (738)

**UNIVERSITY OF LIVERPOOL**  
 DEPARTMENT OF PURE  
 MATHEMATICS

Applications are invited for the post of Demonstrator or Senior Demonstrator in the Department of Pure Mathematics. The post will be tenable for one year, commencing from October 1, 1967, at a salary within the range £895 to £1,285 per annum, according to qualifications and experience.

Applications, stating age, qualifications and experience, together with the names of three referees, should be received not later than September 15, 1967, by the Registrar, from whom further particulars may be obtained. Please quote ref.: RV/158/N. (721)

**AGRICULTURAL RESEARCH  
 COUNCIL**

Meat Research Institute requires Assistant Experimental Officer as a bacteriologist to join small research group concerned with the application of ionising radiations to meat. Candidates will be expected to transfer in October to the new Institute at Langford near Bristol. Qualifications: (under 22) G.C.E. in five subjects including English Language and two "A" level scientific subjects; (over 22) pass degree, H.N.C. or equivalent. Salary: £568 at age 18; £1,017 at age 26 or over, rising to maximum £1,243, with promotion prospects. Superannuation scheme. Application form and further details from: Meat Research Institute, Low Temperature Research Station, Downing Street, Cambridge, quoting CM8. (765)

**JUNIOR TECHNICIAN REQUIRED TO** join a small group working in problems of intersexuality in domestic mammals. Previous experience in histology and histochemical techniques essential. Salary on scale rising to £847 per annum (including London Weighting), according to age and experience.—Apply, in writing, with the names of two referees to the Secretary, Paediatric Research Unit, Guy's Hospital Medical School, London Bridge, S.E.1. (764)

# Director of Research

The Council of the Fruit and Vegetable Preservation Research Association invite applications for the post of **DIRECTOR OF RESEARCH** at their laboratories at present located at Chipping Campden, Glos., but intending later moving to Reading.

The organization, which was formed in 1918, became a cooperative industrial research association in 1952; since then it has received grant aid from the Ministry of Technology. The Association has a staff of 46, of whom 12 are graduates, and the research programme covers the preservation of fruit and vegetables by canning and quick freezing and, to a lesser extent, drying.

Applicants should possess a good honours degree in science and have had experience in food science and preservation; they should also have administrative ability and a creative interest in the food industry. The Director is the chief executive officer of the Association and his duties are many sided.

Commencing salary, within the range of £4,000 to £4,500 per annum, will be according to qualifications and experience. Further details of the post may be obtained from the Secretary, Research Station, Chipping Campden, Glos. Applications, with the names of three referees, should be sent to the Chairman of Council marked "confidential" at the above address by 30th September, 1967.

(726)

**UNIVERSITY OF LONDON**
**CHAIR OF ANTHROPOLOGY AT THE  
 LONDON SCHOOL OF ECONOMICS**

The Senate invite applications for the Chair of Anthropology tenable at the London School of Economics and Political Science (salary not less than £3,570 a year plus £100 London Allowance).

Applications (10 copies) must be received not later than October 3, 1967, by the Academic Registrar, University of London, Senate House, W.C.1, from whom further particulars may be obtained. (767)

**UNIVERSITY OF LONDON**
**CHAIR OF VETERINARY PHYSIOLOGY AT  
 ROYAL VETERINARY COLLEGE**

The Senate invite applications for the Chair of Veterinary Physiology tenable at the Royal Veterinary College (salary not less than £3,570 a year plus £100 London Allowance).

Applications (10 copies) must be received not later than October 23, 1967, by the Academic Registrar, University of London, Senate House, W.C.1, from whom further particulars may be obtained. (766)

**HUDDERSFIELD HOSPITAL  
 MANAGEMENT COMMITTEE  
 HUDDERSFIELD ROYAL INFIRMARY**

**BASIC GRADE BIOCHEMIST** required in the Biochemistry Department of the new Huddersfield Royal Infirmary. Salary scale £855 (plus £108 for Honours Degree) to £1,210 during probationary period of at least two years, thence subject to certificate of proficiency by annual increments to a maximum of £1,658 per annum. The Department is situated in new, well equipped laboratories and serves more than 1,000 hospital beds. The successful candidate will be responsible for routine work, special investigations and research. Whitley Council Terms and Conditions of Service will apply.

Further information may be obtained from, and the Department visited by arrangement with, Dr. R. L. Noble. Apply, with full details and the names and addresses of two referees, to the undersigned.

H. J. JOHNSON,  
 Group Secretary,  
 Huddersfield Hospital Management Committee,  
 Group Headquarters, St. Luke's Hospital,  
 Crosland Moor, Huddersfield. (755)

**UNIVERSITY OF ABERDEEN**  
 DEPARTMENT OF FORESTRY

Applications are invited for two posts of **RESEARCH ASSISTANT**.

The first post to work with Mr. M. S. Philip, lecturer in Forest Management, on the economic survey of some private forestry estates in Scotland. This interesting and important project is concerned with the construction of mathematical models simulating the forest enterprise of each estate. The post is suitable for graduates qualified in mathematics, econometrics, statistics and computer programming. Experience of forestry is not essential but applications from graduates in forestry or agriculture with experience of forest or agricultural economics will be considered.

The second post to work with Mr. J. S. Murray, senior lecturer in forest pathology on *Peridermium pinii*, a rust disease of Scots pine. This rust causes dieback and death of Scots pine trees and is especially prevalent in north-east Scotland. Past work in the department of forestry has dealt with the distribution and incidence of the rust, the biology of infection and development of lesions. Future work will concentrate on the ecology of organisms associated with lesions, the spread of the disease and control measures including genetic resistance in Scots pine. The post is suitable for graduates with training and experience in plant pathology. Experience of forestry is not essential.

Both projects are sponsored by the Natural Environment Research Council and are tenable for two years with possible extension to a third year.

Salary on scale: first post (grade I), £1,420 to £1,945; second post (grade II), £945 to £1,415. All with initial placing according to qualifications and experience. Superannuation (F.S.S.U.).

Further particulars should be obtained from the Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by September 22, 1967. (735)

**CENTRAL PUBLIC HEALTH LABORATORY.** New central media department. Technician/Senior Technician required for routine media control. Some of the work will be of an experimental nature. Experience in microbiology essential and some experience in chemistry desirable. Good working conditions in a new building which has just been completed. Grade according to qualifications and experience. Whitley Council terms and conditions of service.—Applications to Personnel Officer, Central Public Health Laboratory, Colindale Avenue, N.W.9. CO1 7041. (711)

## WHO IS IN CHARGE?

THE world has not been quite the same since Professor K. Galbraith published *The Affluent Society* nearly a decade ago. His wry observation of the condition of modern society may at the time have maddened a great many conventional sociologists by what seemed to be its single-minded determination to prove a simple case, but that opposition is now quite beside the point. *The Affluent Society* was a disturbing and a constructive polemic. It is no accident, for example, that Galbraith's contrast between the private wealth and public squalor should have turned out to be accurately in tune with the ways in which Presidents Kennedy and Johnson have in turn sought to get rid of some of the more obvious bits of public squalor, and it is not, of course, his fault that progress seems to be so slow.

Inevitably and deservedly, *The New Industrial State* (Hamish Hamilton, 42s.) will be widely read. Like its predecessor, it has an apocalyptic sweep which is almost hypnotic. Once again, critics will find themselves having to agree that even though Galbraith seems to them to be wrong, he is likely to be at least half right. Yet the critics will find it easier to make away this time, chiefly because the new book is not merely intended as a sequel to *The Affluent Society* but as a more comprehensive conceptual framework within which Galbraith's observations on the condition of modern society can be accommodated. As such, *The New Industrial State* is vulnerable in two quite different ways. For one thing, it is written with the open intention of changing people's minds and not as a work of scholarship, which means that there will be endless disputes about the validity of Galbraith's assertions. It is also a kind of doomsday book. Galbraith is not only deeply pessimistic about the way that things are going, and also considers that technology is one of the most immediate dangers. That will not immediately win him everybody as a friend.

The starting point of *The New Industrial Society* is a series of paradoxical observations about the modern society, some of them familiar and all of them in some way stimulating or provoking. According to Galbraith, modern industry is neither the embodiment of the kind of capitalism which Marx described nor an extension of conventional statements about the character and the importance of free enterprise, but an institutional phenomenon in its own right. In the great industrial corporations, the commercial swashbuckling of the old entrepreneurs and the managerial interests of the stockholders have been subordinated to the interests of the salaried executives who form a self-perpetuating oligarchy. Corporations and governments are not the enemies which popular myth sometimes supposes, but back-scratching symbionts. Modern

industry is made ponderous and inflexible by its dependence on modern technology—and Galbraith has great fun with a comparison of the three months needed to put the first Ford motor car on the market in 1903 and the three years needed to market a new car sixty years later. For him, more technology means more time, more capital investment, manpower which is more specialized. One consequence of this, the argument goes, is that industries organize themselves in such a way as to insulate themselves as far as possible from ordinary commercial forces such as the vagaries of the market and the supply of capital. Strictly commercial goals are subordinated to other ends. But—paradox on paradox—the growing complication of modern industry entails increasing dependence on an increasingly influential body of scientists and academics—"the Educational and Scientific Estate"—who are by temperament and training inclined to reject the values of the juggernaut they serve. And these, says Galbraith, are precisely the people on whom society must rely for an escape from the monolithic industrial system. Galbraith only properly escapes from gloom in his chapter called "Education and Emancipation".

One of the most urgent questions raised by Galbraith's argument is that of the extent to which technology can be held responsible for the condition of modern industrial society and for its most serious defects. Plainly the charge cannot lightly be dismissed, particularly because there is no reason to think that Galbraith is one of those people for whom society took a turn for the worse when housewives gave up baking their own bread. He has nothing against motor cars as such, but he protests at the manner in which they are produced by huge mindless corporations aiming simply to produce and to survive. One immediate difficulty is, of course, that the corporations may not be as stable and unchanging as Galbraith says they are. Even the biggest among them go out of business from time to time, which is not merely a virtue by the standards of *The New Industrial State* but also something of a proof that market forces have not been nullified entirely. Indeed, the most quickly growing corporations are often the youngest and the smallest—and it is remarkable how willingly the Educational and Scientific Estate in the United States has given these enterprises its blessing. By now, the outskirts of half a dozen American university cities are ample evidence of that.

For what, then, is technology to be blamed? The fact that it now takes several years to put a new kind of motor car into service is in the last resort a consequence of trying to produce motor cars with high performance as cheaply as possible. The first

Henry Ford could move more quickly because his much smaller market could afford comparatively higher prices. To begin with, there was no need to invest huge sums of money in machinery for mass production, and no need to worry about the refined development of the components of which his motor cars were assembled. The link between modern technology and the other aspects of modern industry of which Galbraith complains is very much the same. Efficient production at low cost means planning ahead and persuades industrial corporations to insulate themselves as far as possible from the forces of the market. None of this conflicts with what Galbraith has to say, and indeed he is the first to admit that modern industry is capable enough when only the production of goods is in question. He is, however, a little mischievous, to say the least of it, when he attributes the change which has come over industry to the influence of a seemingly animate entity called technology. Society could have less of technology and therefore less of its supposedly malevolent influence if society would settle for a smaller volume of production.

There must also be doubt about the value of Galbraith's concept of the Educational and Scientific Estate—not quite the same thing as Dr D. K. Price intended a year ago with the title of his book *The Scientific Estate*. For one thing, it implies a degree of homogeneity which may be unrealistic. Worse still, it implies what may be too sharp a distinction between those with a university education and those without. As with what may be called Snow's hypothesis, any attempt like this to cut the community up into intellectually distinct pieces is likely to founder on the rocks of careful observation. But this, perhaps, may not be part of what Galbraith intended, in which case it is a pity that he has given his critics more openings than they deserve. And in the last resort, of course, Galbraith is right to pin his hope for the future—pale though it may be—in the possibility that academics and like-minded people may be able to engage so successfully in the rough and tumble of deciding what goals should be chosen for industry, government and society at large that the modern world will be a better place. To put it at its most trivial, Galbraith is right in saying that you cannot rely on the forces of the economic market to ensure that unsightly advertising hoardings will not proliferate. He is also right in thinking that the universities and similar places are best placed, by virtue of their independence, to provide the kind of influence that society would find healthy. His book will do good in this direction, for it will be widely read and it is bound to be provoking. It remains to be seen whether academics, as is their custom, will think their public duty has been done when they have read the book. It is also an open question whether the strong and sometimes over-clear lines in which Galbraith's picture has been painted will serve as a spur to persuade the Educational and Scientific Estate that it could easily win more creative influence than it has or whether, on the other hand, it will become another excuse for inactivity.

## NO OIL ON WATER

SOME details of the appalling destruction of sea birds caused by the wreck of the Torrey Canyon are reported on page 1123 of this issue in a survey of 1,223 dead birds collected on Cornish beaches during the month following the disaster. What stands out is that mortality was almost exclusively restricted to two species of offshore swimming birds—78 per cent of the sample was guillemots and 20 per cent razorbills. Other species appear to have escaped major killing. The same two species formed respectively 81 per cent and 17.5 per cent of the much larger sample of 7,849 birds taken at the Cornish cleaning stations. A summary provided by the Royal Society for the Prevention of Cruelty to Animals (see page 1119) draws attention to the very low survival rate of birds at cleaning stations. Above 450 of the 7,849 had been rehabilitated on April 1 and many of these have since died. A similar fate befell most of the 2,000 birds taken to cleaning stations in France. In other words, a little over 10,000 birds are known to have died and, given all the difficulties of recovering oil-soaked bodies, it is likely that total of anything between 30,000 and 100,000 birds were killed.

Luckily, the damage to the English sea bird populations is not likely to prove permanent. Even the breeding populations of the southern guillemot *Uria aalge albionis*, which has for the past fifty years suffered increasingly from oil pollution, are expected to recover. The populations of puffins, guillemots and razorbills on the coast of Brittany have, however, suffered very badly and may well fail to recover.

As the figures show, and as the RSPCA and the Royal Society for the Protection of Birds would be the first to admit, the magnitude of the Torrey Canyon disaster completely overwhelmed the facilities of the cleaning stations. When oiled birds are arriving in thousands, there is little hope for most of them. An oiled bird is to be cleaned and successfully rehabilitated it must be given constant and individual attention and many ornithologists believe that in emergencies like the Torrey Canyon wreck, it is better to kill birds than to prolong their suffering in vain attempts to clean them. But if attempts to save birds are to be made at all, there is an urgent need of many more cleaning centres, perhaps mobile ones, and much more research into the way of cleaning contaminated birds. Apparently some of the £60,000 collected by the Wildlife Fund, the RSPCA and the RSPB in the joint Seabird Fund appeal is earmarked for this, the £5,000 which the British Government contributed is to pay for the work done last spring—but the amount available are not sufficient for all the future work that is needed. The RSPCA alone spent £7,000 on cleaning operations after the Torrey Canyon wreck.

The figures in these reports show just part of the suffering that can result from a massive pollution of the sea, and unfortunately the Torrey Canyon disaster, though by far the worst in British waters, is by no means an isolated incident. Last year, 1,700 tons

oil were accidentally pumped from the German tanker Seestern into the River Medway—an estimated 8,000 birds were among the victims—and earlier this year a Greek tanker left behind 250 tons of oil in Milford Haven. What is being done to prevent oil pollution in the future? The shipping world is slowly accepting that the sea must not remain its largest and cheapest dustbin. An indication of this is that the Japanese Government seems to be on the verge of formally joining the Convention for the Prevention of Oil Pollution of the Sea—which does not imply that Japanese ships are responsible for most oil pollution. The Convention, which is now supported by the governments of all the major maritime powers except Japan and the USSR, designates zones throughout the world where the discharge of oil is forbidden. Of course, it has no legal powers; if a ship breaks the rules on the high seas and is caught—which is rare—it can be punished only by the country of registration. There is a tortuous legal procedure by which any member nation which spots a transgression anywhere in the world reports the evidence to the flag government which, if satisfied that the evidence is sufficient to provide a case against the ship according to its own law, should take immediate proceedings against it. If Japan, the fifth largest maritime nation, does in fact join, the Convention's moral authority, if nothing else, will be greatly strengthened.

But obviously the only effective way to stop voluntary pollution is to remove the financial incentives. This could be done by making fines imposed on ships caught discharging oil so severe that ships' masters would not dare to risk the penalties. For example, why should not the signatories to the convention agree to ban from their ports any ship known to have caused wide-scale pollution? A subcommittee of the Inter-Governmental Maritime Consultative Organization (IMCO) is to meet in London next week and will be considering, among other things, ways of increasing the penalties for oil pollution, but nobody seems to think it will go so far as to recommend such radical measures.

Deliberate pollution is much more likely to stop when the oil companies develop ways of recovering the oil previously discharged and saving themselves some money. In the past, oil tankers returning empty to the land fields have washed their tanks at sea to save a few hours sailing time and have discharged the washing—oil and seawater. A system known as 'load on top', which prevents some of this waste and pollution, has been developed by the oil companies. With 'load on top' the tanks are washed with hot sea water, and all the washings are collected into a tank to separate, when the lower aqueous phase can be discharged. The oil companies make great claims for this system and even conservationists agree that it represents a considerable improvement, but an IMCO study found that it is not entirely within the pollution limit that the convention sets. 'Load on top' is still only a compromise between the old discharge system and the use of really effective separation plants. None the less, if it really

does save money and reduce pollution as well, we can be sure it will find widespread acceptance.

Even in the unlikely event of all deliberate pollution ceasing, the risk of accidental pollution is increasing as more and more oil is transported. There will always be the spectre of a one or two hundred thousand ton tanker being wrecked. After the Torrey Canyon disaster, the British Government called for a special session of IMCO, which met in May, and which began a series of urgent studies into sea lanes, speed limits, crew training, construction of tankers and procedures for mobilizing national and international efforts to deal with pollution. Despite the protestations of the oil companies to the contrary, these studies clearly imply that the standards of safety and navigation of tankers can be greatly improved. As Torrey Canyon showed, to save a few hours sailing time some masters seem prepared to cut safety margins.

IMCO has also set in motion research into ways of dispersing oil without destroying marine flora and fauna—one of the problems of the Torrey Canyon disaster was that no one knew the toxic effects of the detergents used. The results of the IMCO studies are to be presented in 1968 and, if nothing else, they should lead to sensible speed limits and better defined sea lanes. The problem, however, as with all other international agreements, will be one of enforcement. Tradition apart, it is difficult to understand why shipping should not be as closely regulated as aircraft. May not the concept of untrammelled freedom of the high seas outlive its usefulness?

Apart from trying to prevent accidents, IMCO is also tackling the more important job of devising procedures for accidents. Delays in burning the Torrey Canyon, wrecked outside territorial waters, and the subsequent events leading to the melodrama in Singapore, where her sister ship was arrested by the British Government and only released on £3 million security, revealed the complete lack of internationally accepted procedures for obtaining adequate compensation for people and governments which suffer directly from pollution and for allowing a government to destroy a potential pollution hazard. Groups in the various member nations of IMCO are investigating the legal responsibilities of shipowners and masters whose vessels, though wrecked on the high seas, damage the livelihoods of an adjacent country. It is essential that some sensible code of practice for third party insurance be devised (*Nature*, 214, 1; 1967). They are also studying the extent to which a state threatened by a wreck outside its territorial waters can protect itself even if that necessitates destroying the vessel and cargo and so affects the interests of shipowners, salvage companies, insurers and even flag governments. The maritime nations must reach some firm agreement on this quickly and accept the inevitable but probably small increase in insurance costs. It is inconceivable that when the next loaded tanker is wrecked, it should be allowed to spew out thousands of tons of oil while there are protracted legal discussions between the parties involved.

## STRENGTH THROUGH MISERY?

THE British Association seems to have had a successful meeting this year, and there is nobody who will be sorry. A great many people with puritan inclinations will, however, be delighted to observe that adversity seems to have brought out the best in the association. It is several years now since the association suffered its chronic penury in silence. Instead, it has taken to complaining that the British Government does not reward it properly for doing what is in the last resort a public service—the provision of a lecture service for young people. More recently still, the association has been dropping hints that if the Government does not pay up, the public service will have to go by the board. But this quite proper concern with the health and otherwise of the balance sheet seems to have spurred the association to a wider consideration of the foundations of its continued existence. One way and another, it seems to have resolved that if the world will not give it a living, it must make one for itself. That is a healthy state of mind.

These, however, are only the beginnings of change. The association is still bound in many ways to the traditions of another century. The annual meeting remains partly—not entirely—an anachronism. It covers too much ground and is too didactic. Triviality is being chased away, but there is still some way to go. Nobody is quite sure what purposes are served by the meeting, although most of those who participate enjoy themselves. There is a danger that the indiscriminate encouragement of good works will persuade the association into the encouragement of mediocrity, which implies that there should be some kind of hurdle, however innocuous, to improve the quality of what young people are invited to exhibit in what is called the science fair. There is also a case for a deliberate erosion of the sense of comradeship which sometimes divides the old hands from those who have only recently joined the association, which implies that there might be great profit in some kind of system under which certain officers of the association were elected—one man, one vote—by card-carrying members. As things are, the association must be unique among modern institutions in not offering those who pay to belong any sense, as of right, of influencing the course of events. Anyway, throw the presidency open to election? That would kill a dozen birds with the same stone. In its attempts to import real live public issues into its proceedings, the association has not been entirely successful—which is no reason for going back to platitudes. There is a great deal that the association could do as a lightning conductor for public controversy.

But is it really wise to let everything depend on the success of the annual meeting? That is a question the association has been asking itself for several years. The answer is no, which is why the association has been trying to diversify its activities. Its lecture

service for young people (and adults) has been a moderate but not an outstanding or even an indispensable success, but this now seems threatened by the lack of money. This is inevitable. The association cannot hope to win its reputation by spotting tasks that other people should already have undertaken and then assure its survival by being paid to carry them out. Rather, it must expect to live by its wits, starting up new projects and then handing them over to others to finish off. This is why, in the long run, it will be best if the association can struggle back towards a conception of its public function much more like the one it used to carry out a century ago, when it used to startle its contemporaries with perceptive and authoritative studies of urgent problems inseparable from or occasioned by the growth of science. The association could do worse than become a writer and distributor of tracts. The association would have to learn somehow to escape from the convention of good manner which at present inhibits it, but it would discover that independence is cheap and exhilarating as well.

## COSMOLOGY TO PLAY WITH

THE discovery in the past few years of the cosmic black-body radiation may not be a final proof that or kind of cosmology is preferable to another, for it still not beyond the bounds of possibility that the advocates of steady-state theories will somehow be able to turn the tables on their rivals, but it has already proved to be a powerful stimulus to productive speculation. The calculation by Dr K. C. Jacobs which appears on page 1156 is one valuable illustration how curiosity has been fired by the recognition that the universe appears to be filled with microwave radiation corresponding to a temperature of about  $3^\circ$ . Jacobs sets out to construct a realistic model of universe which, starting from a dense concentration, largely dominated by radiation for the first 2,000 years of its existence. Thereafter, matter and radiation are not strongly in interaction with each other. To begin with, of course, the outward movement of the matter of which his model is composed is rapid but rapidly decelerating. As time goes on, the deceleration itself diminishes. This sequence of events is a more plausible version of the kind of model obtained when a universe dominated by radiation is joined discontinuously to one dominated by the presence of matter. The numbers in the model which Jacobs has constructed are immediately of importance than the possibility that the universe in which there is a transition for a rapidly decelerating to a less rapidly decelerating universe might account for the way in which the red-shifts of quasars seem to be bunched around certain values. In other words, there is a possibility that models like these may yet be put to some kind of test.

## NEWS AND VIEWS

### Graceful Decline

THE National Coal Board seems to be presiding successfully over the gradual contraction of the coal industry in Britain. The board's annual report for the year ending on March 31, 1967, shows a small profit of £0.3 million, after the payment to the Government of £28.2 million interest, which is a tiny proportion of the total cost of the board's operations—£890 million in the year just past. The production of coal in 1966-67 amounted to 173 million tons, a decline of 0.3 per cent in the year. The labour force in British collieries continues, however, to decline even more quickly, which implies an increase of productivity amounting to 1.4 per cent in the year. The board says in its report that it was able financially to break even only because of an increase of output and of productivity towards the end of the year. At the beginning the rate of loss of miners from the industry was so great—amounting to 1,000 or so a week—that the efficient operation of the collieries was impeded.

The report will as always be scanned carefully for evidence of the directions in which British fuel policy is evolving. The National Coal Board seems now conciled to a further decline in the scale of its operations under the combined pressures of competition from natural gas and nuclear power. The report, however, repeats the board's well known view that the exploitation of new sources of fuel should be "so regulated as to secure the greatest advantage to the economy as a whole, now and in the immediate future".

It is particularly outspoken about the building of clear power stations. "Nuclear stations cost huge sums in capital, and account needs to be taken of the cost to which the excess capital expenditure could be put if it were not sunk in these stations. To the extent that the basic technology remains unproved, the justification for spending these large sums of capital must be open to question. And if the second generation stations are but a step along the road to the development of the fast breeder reactor stations, it would not be logical to make this step no larger or more expensive than it needs to be. The mistake of an over-zealous experiment which was made in the first nuclear programme ought not to be repeated."

In practice, the National Coal Board seems to be doing well in its resistance to over-rapid contraction. Earlier this year it was agreed that coal production should amount to 155 million tons a year at the end of the decade—15 million tons more than the natural demand and for coal estimated by the Ministry of Power. Before the publication of the annual report, the board also announced a month long halt in the process of shutting down collieries as part of its strategy of entraining production where coal can be won profitably. Although this agreement between the board and the British Government is prompted by a wish to limit or at least to restrain a further increase of

unemployment, the long-term result could well be still more coal in 1970. Much will depend on how resolutely the Government can hold to its cheap fuel policy.

### New Faces on the Front Bench

THE changes in the British Government which Mr Wilson set in motion at the end of August now seem to have been completed. At the Department of Education and Science, the duties of the two Ministers of State have been decided; Mrs Shirley Williams will be responsible for the universities and the research councils, while Miss Alice Bacon will look after other problems, schools and teacher supply among them. There will be widespread interest in universities and research councils over Mrs Williams's appointment; although she has only been a member of parliament since 1964, a considerable reputation has preceded her to the department.

At the Ministry of Technology, an appointment has been made to replace Mr Edmund Dell, who was transferred to the Department of Economic Affairs as a Joint Under Secretary. Mr Gerald Fowler takes over Mr Dell's old job as Joint Parliamentary Secretary at the Ministry of Technology. Mr Fowler has spent most of his career at the University of Oxford as a lecturer, but spent a year at the University of Lancaster before his election as MP for The Wrekin in 1966.

### BA at Leeds

THE 129th meeting of the British Association for the Advancement of Science seems to have been a success. This year the association visited Leeds for the fourth time, and the meetings were held in the buildings of the University of Leeds. As usual the association was catholic in its choice of subjects, and the 3,200 delegates who turned up could listen to dissertations on subjects as diverse as the changing face of West Yorkshire, or the control of crime. In general it seemed that the specialized section meetings were more successful than the attempts to involve a larger public by symposia on subjects such as science policy or the reasons why children do not choose science as a career. The best discussion of the public role of scientists, for instance, was to be found in the section devoted to the sociology of science.

The BA is showing some talent in adjusting to reduced circumstances. Last year it made a small profit, apparently by cutting its coat to fit its cloth, after appeals to the Department of Education and Science for more money had gone unheard. Despite this, its organization, particularly at the grass roots, is ill defined to say the least of it, and even those involved find it hard to explain. The current financial squeeze for the BA, which everybody hopes will be only a temporary phenomenon, offers an opportunity for reorganization which the association would be unwise to miss.

### Saudi Arabia and Telescopes

LAST week Dr Abdul-Aziz Khowaiter, the vice-rector of Riyadh University, Saudi Arabia, put forward a tentative proposal for the construction of an optical

telescope near Riyadh. The maintenance and operation of the telescope would be undertaken by British scientists, for the first few years at least. The proposal was prompted by a BBC overseas broadcast, "Science and Industry", in which Sir Bernard Lovell said that no new telescopes had been built for eight years. In October, Sir Richard Woolley, the Astronomer Royal, is visiting Riyadh as a guest of the vice-rector to look into the possibilities of the project. Until the new university at Jeddah opens, the University of Riyadh is the only one in Saudi Arabia with science faculties. A department of astronomy was set up this year, under the direction of Mr Robert Seeds, a British lecturer.

## The More we are Together

THREE bodies which represent chemists in Britain are contemplating amalgamation. The Chemical Society, the Royal Institute of Chemistry and the Society of Chemical Industry have agreed that an independent investigation should be undertaken with a view to making recommendations about amalgamation. Sir Eric Bingen, a former Deputy Chairman of Imperial Chemical Industries, Ltd., is to carry out the investigation. His first task will be to assess the work done by each of the societies, and to work out ways in which the essential activities of each may be maintained within an organization incorporating all three. His report will be complete by the end of the year, and each of the societies will be taking it with them to their annual conferences in the spring of 1968.

The idea of amalgamation has been talked about for many years (see *Nature*, **214**, 335; 1967). Casting envious eyes at the American Chemical Society, previous presidents of the British societies have felt that British chemists might be better represented by a larger society on the American model. The functions of the American Chemical Society are in Britain carried out by half a dozen different societies, none of which alone can truly be said to represent chemists. The Royal Institute and the Chemical Society already have some joint activities; together they publish *Chemistry in Britain*, and their annual conference next year in Dublin will be a joint affair. At the local level, the three bodies hold joint meetings, and it is not uncommon for officials to overlap between the societies, holding local office in one society one year, and in another the next. With a combined society of 40,000 chemists, it is felt, better representation and perhaps administrative savings would be possible.

The latest move towards amalgamation seems to have been the joint inspiration of the three presidents. Sir Harry Melville, President of the Chemical Society, sparked it off in a recent speech, and since then has met Mr N. A. Iliff, President of the SCI, and Mr L. H. Williams, President of the RIC, for talks. Sir Eric Bingen was selected for the task of bringing the three societies together because of his success in an equally delicate operation, organizing the amalgamation of the Association of British Chemical Manufacturers and the Association of Chemical and Allied Employers into the Chemical Industries Association. How Sir Eric will work is not clear, but he has already had talks with the three organizations. The three presidents are playing their cards close to their chests, and saying nothing.

## Paper Productivity

WHILE the United States engages in doctorate production (*Nature*, **215**, 805; 1967), India seems to concern itself with the "productivity of publications". This is one of the section headings in a report issued by the Indian Council of Scientific and Industrial Research in its "Occasional Papers Series", entitled *Scientific Research in India; an Analysis of Publications*, by Dr B. V. Rangarao. It appears that 10 or 12 scientist years are required to produce one Indian paper. By far the biggest output of papers came from the universities, with 3,800 out of the 9,800 published in all of India in 1965. Top of the paper production league is the University of Calcutta, with 279 papers, closely followed by Agra University (260). The report does not actually name the unproductive laboratories; it merely observes that "though there are a large number of research units in the country, the activity is serious only in a small number of them", and warns that "it may be worth studying the *per capita* publication in different organizations".

Medicine is the subject of most Indian papers indeed, of the 64 papers from the University of Patna 44 were in medicine. By contrast, workers on electricity, thermoelectricity and electric lights are completely uncommunicative. The report bemoans this but gives no account of how many people there are either to produce the papers or to read them. Team work, Dr Rangarao continues, is of the essence; most papers published in the advanced countries are by two joint authors, but in India the rule still seems to be one man one paper. "Even in the technological universities, where team work should be easy to organize the average authorship is only 1.6. This aspect requires some critical analysis . . ."

The report is somewhat at a loss to explain the low output of scientific papers in India. The thirteen most prolific universities were neither the oldest nor were they better endowed. The best explanation seen therefore, to be that Indian scientists are uninterested in interdisciplinary activity and prefer to work alone. Cure this, and paper productivity and average authorship will no doubt rise.

## Tropical Aid

IT seems that the appointment of Dr P. C. Spens as director of the Tropical Products Institute from March 1967 has been a very good thing for all concerned. The Tropical Research Institute aims to provide sophisticated research which developing countries cannot afford, and technological development work aid their industrialization programmes. A radical organization took place during 1966, so that an emphasis could be placed on food science and technology, industrial economics, industrial engineering and process development. Signs of change are also seen in the annual report which was published last week. Instead of giving incomplete progress reports on the year's work for all the current projects, as in the past, the report now includes short monographs that are complete in themselves, on a few selected ones.

The first of these deals with the report on production of protein products from oilseeds for the relief of malnutrition. This report has been written as a guide

those who have to cope with malnutrition problems and indicates sources of protein for dietary improvement as well as production methods which might be suitable for particular local conditions. Product distribution is considered to be a very important part of any scheme of this nature. Prospects in the market for bananas, and costings for orange squash production have been subjects for reports. The natural products chemical research division reports on three of its current projects. The fungus growing on mouldy corn has been found to cause disease in pigs and cattle that eat it, and the toxins produced by *Penicillium rubrum* are thought to be the cause. The mycotoxins section of the institute has been working on these toxins and has found, in experiments with mice, that damage is caused to the liver. Work on the chemistry of scirpentriol and verrucarol is also described, the interest being in reactions leading to detoxication. Diacetoxyscirpenol has been implicated in the important problem of mouldy corn toxicosis. There has also been a search for reasonably simple, naturally occurring antifungal molecules which are obtainable by synthesis, but results have proved disappointing so far. Investigation is still going on into more complex molecules.

The services of the Tropical Products Institute are available to almost any country and enquiries were received from eighty-eight different countries during 1966. The work of the institute is growing, as seen in the budget figures for the last two years. For 1966-67 it was £360,000 and for the current year, 1967-68, £444,000.

## Finding Bombs

In August a panel of experts met at the International Atomic Energy Headquarters in Vienna to discuss techniques of ensuring that atomic installations are not used for military purposes. The members of the panel came from Canada, India and Japan as well as the four nuclear powers which are members of the agency. In addition, there were observers from West Germany, Czechoslovakia, the European Nuclear Energy Agency and Euratom. The British member of the panel was Dr Frank Morgan of AWRE Aldermaston; Mr D. B. B. Janisch of UKAEA Risley and Mr J. McAdam Clark of the Ministry of Technology were present as observers.

The panel discussed how to verify statements on the movement of fuels, and the production of plutonium and electricity by a reactor. Methods of non-destructive analysis of nuclear fuel, and of sealing techniques, were also considered. The panel concluded its work by commending the directions the agency's research and safeguards techniques should take.

## Immigrating Animals

The most unusual immigrant granted right of entry to Britain in 1966 may well have been the rhinoceros imported in a West German Zoo. Other rare wild animals which import licences have been granted are listed in a report published by the Advisory Committee on Animals (Restriction of Importation) Act, 1964 (MSO, 3s.). This report is the first of an annual summary of statistics of animal importation and gives numbers of licences granted in 1965 and 1966.

The Advisory Committee concentrates on conservation of wild animals and advises both the Board of Trade, which grants the licences, and the Customs, who enforce them. The animal families are classified by rarity into two groups, rare and not so rare. During 1966, 22 Anthropoid Apes (Pongidae) were refused admission. Conservationists will also be pleased to learn that in 1966 as compared to 1965, a larger number of licences was granted to only two of the 17 families mentioned. These two were opossums and marmosets. The highest figure is, surprisingly, not for Old World Monkeys (Cercopithecidae, 21,066) but for tortoises (Testudinidae). Despite a fall of 16,446 from the previous year it still stood at 320,573. The committee says that the life span of this animal must be severely reduced when it comes into Britain. As yet it does not know what effect this trade is having on the animal in its wild state in any particular area.

The rest of the report covers countries of origin of the animals and declared purpose of importation—the latter is divided into the four categories of exhibition, scientific research, pets and resale. The rhinoceros was heading for exhibition, but one of the 16 opossums was named as a pet. Despite the appearance of the wombat in the list of the rare animals, it seems that nobody has attempted to import one in the past two years. The statistics refer to the number of licences issued, not to the number of animals brought in. They are therefore in some way misleading, for not all the licences were taken up. During last year, however, the Board of Trade changed the system so that 1967 will be the first year in which the number of animals arriving will be accurately known.

## New Man at Argonne

It has been announced that Dr R. B. Duffield is to become the Director of the Argonne National Laboratory of the United States Atomic Energy Commission. He will take up his appointment in November. Immediately after receiving his doctor's degree from the University of California at Berkeley, in 1943, Dr Duffield became a member of the team of workers on the Manhattan Project at Los Alamos Laboratory. In 1946, he joined the staff of the University of Illinois where he worked for ten years, finally becoming associate professor. He then became chairman of the chemistry department of the General Atomic Division of the General Dynamics Corporation, where he directed first the design and later the operation of the high temperature gas cooled reactor at Peach Bottom, Pennsylvania. His work in connexion with this brought him on many visits to the Dragon Project at Winfrith which collaborates with the Peach Bottom team. Dr Duffield will be the first chemist, as opposed to a physicist, to direct Argonne, and there may be significance in the fact that his recent experience has been concerned with reactor research; his predecessor, Dr A. V. Crewe, returned to the University of Chicago to continue basic research.

## Exporting Science

In spite of the trouble in Nigeria and the devaluation of the Indian rupee, the British Council remains

optimistic about the future of its aid programmes in scientific education. Four of the seven scientific education officers, all of them in Commonwealth Africa, had been appointed to Nigeria. The officer in Enugu, Mr G. Howell, was able to return on leave and no equipment or buildings appear to have been damaged. Even so, the Nigerian war will undoubtedly set back the council's plans for scientific education which had been progressing splendidly; last year the number of scientific education officers equalled the number of scientific liaison officers for the first time. In India, the devaluation of the rupee has had an effect on the low priced books scheme, effectively increasing the price of British books, while American and Russian scientific literature can be bought without hard currency.

The report of the Science Advisory Committee of the British Council was, in fact, issued before both the Nigerian and Arab-Israeli wars. The council administered seventy-two scientific bursaries for three or six months research and training in Britain, and 118 scholarships were awarded, many of them in science. There is, apparently, an "untouched reservoir of scientific talent" in Latin America, Japan, Israel and certain other countries, but in the rest of the world the number of scholarships available is in proportion with the number of candidates. Under a new agreement, the number of exchange studentships available in the Soviet Union will rise from 22 to 45, but the council anticipates difficulty in filling this quota for 1968-69. Applicants for studentships must be graduates working at recognized institutions and must be competent at Russian. It would seem that most of the few people with appropriate qualifications will already have been to Russia on previous studentships. The council will soon be advertising for students for 1968, for the smaller quota for 1967 has already been filled. Of the Warsaw pact countries, only in Poland is the work of the British Council not governed by an official exchange programme. Polish students are able to travel independently to Britain and many do. Perhaps because of this, scholarship applicants from Poland are of a very high quality.

In all, 12,350 scientists visited Britain in 1966-67 under the auspices of the British Council, but only 1,370 British scientists attended courses, held scholarships or took up appointments abroad. Most of the movement of scientists took place within Europe. Only four British scientists visited non-Commonwealth Asia and only 140 came from that region to Britain. But it is interesting to see that four times as many workers came from South America as from Australia, Canada and New Zealand, and that nearly as many Britons took up scientific appointments there as in the underdeveloped parts of the Commonwealth—good news indeed for those who have felt Britain to have been too long neglectful of early ties with Latin America.

### Students' Living

THE design of living accommodation for students has been considered by the Department of Education and Science and the University Grants Committee (*Student Residence*, HMSO, 10s. 6d.). The study, issued as a Building Bulletin, explains the conclusions reached by a joint working party from the two organizations which, with the Scottish Department and the Building

Research Station, has investigated how different buildings have been designed and what they cost.

First, the different space requirements for a variety of activities are discussed. The area needed for study can be considerably reduced by using desks with fold-down fronts. The bed is the largest single item, but there are various ways of diminishing its bulk by day. In the United States, the report says, beds which fold back into the wall have been installed in some student accommodation, but this type of fitting is usually expensive. In Britain, the current philosophy seems to be to design a bed which can be used as a settee during the day, often by sliding it back into the wall and using the space underneath for storage. Several of the colleges mentioned have adopted this approach, and at the Henry Price Flats at the University of Leeds conventional sheets and bedding have been abandoned in favour of sleeping bags. Space is also needed for washing, dressing, heating appliances and finally for conviviality. The move towards small student rooms which cost less to build has meant that entertaining in student rooms is severely curtailed. One possibility is to provide separate entertainment areas for each group of student rooms. Adding up the spaces needed for different functions gives a bare minimum size of 70 sq. ft. for a study-bedroom, although in recent years the UGC has been more generous than this, providing about 110 to 140 sq. ft. per person. Alas for aesthetics, the report concludes that long, narrow rooms are cheaper to build, provide better use of space and a clearer division of function.

The report also discusses the provision of other facilities, such as communal and recreational areas. These drastically increase costs. A grant sufficient to house 200 students in a residential annexe would house only 130 if full allowance were claimed for additional facilities. For this reason the UGC and the Department of Education and Science are unwilling to approve such facilities without justification. High tower blocks come in for some criticism; they cost more to build because of the need to provide lifts and the fact that they cover a greater area for each student housed. Firmer foundations, fire precautions and the need for more durable materials can also add to the cost of tower blocks. Since the towers require more space between them, claimed savings in land costs may not be realized. Unfortunately, the demands of cost and aesthetics are rarely in step but, as the photographs in the report show, it is possible to achieve attractive compromises.

### Money for Schools

LOCAL education authorities in England and Wales are to receive a special allocation of £16 million for the building of schools in "educational priority areas". The concept of these areas was formulated in the Plowden report, but the areas are not to be formally designated; instead, local authorities have been asked in a departmental circular, to apply for grants for the reconstruction or replacement of both primary and secondary schools which are not up to standard.

This news will no doubt be very welcome, for in 1964 and 1965 far fewer new schools were begun than usual, because of economic conditions. As a result correspondingly few schools have been completed recently. Earlier this year the then Secretary of State

for Education and Science, Mr Anthony Crosland, said that the building of eighty million pounds worth of new schools was begun in 1966-67. The rate at which Britain is building new schools has therefore returned to where it stood in 1962 and 1963.

At the same time as the news of this special allocation comes details of a slight increase in the amount education authorities will be able to spend on "minor works", worth less than £20,000, which do not require permission from Whitehall. The amount set aside for this will now be £27.5 million.

## Britain by Numbers

THE latest *Abstract of Regional Statistics*, issued by the Central Statistical Office (HMSO, 10s.), covers a lot of ground. As well as the tables of population and area, fuel and power, production, construction, distribution, transport and education, there are three new tables. These cover the number of agricultural holdings, a survey of personal incomes in 1964-65, and a survey of average gross annual earnings.

Many of the tables reflect the erratic progress of the British economy in the past ten years. Unemployment, up to 2.6 per cent in 1963, was down again to 1.6 per cent in 1966—the last year for which figures are given in the abstract. Now it is up to near the 1963 peak once again. Steel production reached peaks in 1957, 1960 and 1965, but has now declined from the 1965 figure of 27 million tons to 24.3 million tons in 1966. Deep mined coal shows a steady decline since 1956, from 207 million tons, to 166.5 million tons in 1966. The profitable coalfields in Yorkshire and the East Midlands, on the other hand, show only a very slight decline. Over the ten year period, the number of miners in the pits has fallen from nearly 700 thousand to 426 thousand, while open cast mining has shown an even faster decline. Output per man-shift in coalmining has, however, increased rapidly, from 24.7 cwt. in 1956 to 36.4 cwt. in 1966.

New tables compiled by the Ministry of Social Security gave figures for annual earnings of people in civil employment in much greater detail than before. These show that the average gross earnings for men in the age range 18-64 increased from £1,033 in 1964-65 to £1,104 in 1965-66. The figures for women are far lower, £525 in 1964-65 and £558 in 1965-66. This includes married women, who tend to earn less than spinsters; the figure for unmarried women was £601 in 1964-65 and £638 in 1965-66. The earnings are also broken down by area; men in the GLC area earned an average of £1,204 in 1965-66, against the national average of £1,104. The worst paid men were those in East Anglia, with annual earnings of £1,007.

## Problem Solving

THREE British research associations—the British Cast Iron Research Association, the British Welding Research Association and the Production Engineering Research Association—have formed one of the largest known organizations for solving production problems and improving manufacturing efficiency. The organization, called the Production Advisers Consortium (PRODAC), will provide a pool of more than 1,200 engineers, metallurgists, designers, economists and

other qualified people to carry out research into all problems of production from the initial raw metal to the final marketing and distribution.

Hitherto, companies wishing to sponsor research could only use the services of the associations of which they were members, but under the new scheme the research teams of all three of the associations will be at their disposal. The research and advisory service is available on a confidential fee-paying basis to any member of one of the research associations, with the exception of a member firm which has resigned from the research association whose advice is sought. PRODAC will not replace the normal service provided by each research association to its members, for it will be concerned solely with sponsored or repayment work.

The consortium will be controlled by a consultative board consisting of Dr D. F. Galloway, director of the Production Engineering Research Association, as chairman, Mr H. Morrogh, director of the British Cast Iron Research Association, and Dr R. Weck, director of the British Welding Research Association.

## More Dead Birds

THIS Table, provided by the RSPCA, gives details of the commoner species of birds which, contaminated by oil from the Torrey Canyon, were sent to cleaning stations by April 17. Of the 443 birds listed as rehabilitated, many have since died either in captivity or on release.

Cleaning and reception station	Alive	Died	Guillemot	Razorbill	Shag	Puffin
St. Ives 1	76	3	313	62		
2	251	45				
Veryan 1	308	300	495	98	2	7
Newquay 1	153	62	175	38	1	1

## Progress in Instruments

ANOTHER year of rapid expansion in the activities of the Scientific Instrument Research Association is reported by the chairman in his annual report for 1966. The industrial income in support of group-sponsored projects has risen by 380 per cent over the past three years to £66,800. Income from subscription has increased by 23 per cent over the three year period to £72,200 and income from sponsored research has increased to a record level of £100,711. As a result, the association is negotiating with the Ministry of Technology to increase the ceiling of its grant. The total budget of the association reached the figure of £438,000.

Expenditure on industrial measurement and control projects increased from £75,000 in 1965-66 to £145,000. The association has decided to recruit staff to undertake technically oriented market research and has set up an industrial communications group to provide a broader base for its information department and to help in the task of spreading technical knowledge by every possible means, especially in automation.

One of SIRA's many projects is making thin film microcircuits by laser micromachining. A magnified pattern of the film to be removed is reproduced in a mask which is illuminated by a Q-switched pulse of radiation from a laser. The optical image of the mask is focused on to the thin film and, when the laser is fired, the areas of the film exposed to the laser radiation evaporate. Successful experiments have been carried out with nichrome, cermet, chromium, gold and aluminium. The possibility of applying this technique to graticule production is also being studied.

## Elephants Caught

AN aerial technique employing poisoned darts, shot from a crossbow by a marksman in a helicopter, has been used to capture young elephants during preliminary trials in the culling of herds in the Kruger National Park. Dr U. de V. Pienaar describes in the latest edition of the *Journal for Scientific Research in the National Parks of the Republic of South Africa* (No. 101; 1967) how a method already used successfully to catch rhinoceros in Kenya has been applied to young elephants—poisoned darts are already used to capture adults from the ground.

A helicopter first located a herd of breeding elephants, and waited until the ground party arrived. The helicopter then swooped in on the herd, usually causing it to stampede, and at a range of twenty-five to thirty yards suitable calves were shot with darts containing 1 mg of propylorvinol hydrochloride, and 7 mg of acetylpromazine maleate in a volume of 3 ml. After about 10–15 min the calves which had been hit fell to the ground, and the ground party moved in. A nylon thread was passed around the elephant's neck and this was pulled into an open crate. The antidote to the immobilizing mixture was administered to the ear-vein and the animal rose to its feet within minutes to be guided into the crate. Any mothers which attempted to rescue their young, which they often did, were kept away by the helicopter. In cases where the mother refused to leave a very young calf she was also immobilized.

After being tamed and adjusted to captivity the young elephants were shipped to America. The method proved very successful; twenty-seven young elephants, aged between 12 and 56 months, were captured in seven days of hunting. The great danger involved when breeding herds are disturbed by hunters operating on foot is avoided with the use of the helicopter, and the captures are made without damage to elephants or hunters.

## Ångstrom Ruler

from our Molecular Biology Correspondent

THE phenomenon of excitation energy transfer has found occasional use in biochemistry, notably as a method for following binding processes by sensitization or quenching of fluorescence. Despite much interest and effort, however, its application to the study of topological detail in macromolecules has for the most part given trivial and disappointing results. Promise of better things comes from work of Stryer and Haugland (*Proc. Nat. Acad. Sci. US*, **58**, 719; 1967), which should both please the spectroscopist and stimulate the biochemist.

An energy transfer system is set up when two fluorescent molecules are brought into proximity to one another; if there is large overlap between the emission spectrum of the first and the absorption spectrum of the second, and the geometry is favourable, excitation of the first molecule (the sensitizer) by irradiation at a wavelength in its absorption band leads to fluorescence from the second (the emitter). In such a system, no matter what the wavelength of excitation, fluorescence will always come from the species emitting at the lowest energy (longest wavelength). The theory of energy transfer, in terms of resonance between the transition dipoles of the two molecules, was developed twenty years ago by Förster, and predicts that the extent of transfer will vary inversely as the sixth power of the mean distance between the molecules ( $r^{-6}$  dependence). Whatever the situation in free solution there seems little doubt that excitation transfer between chromophores fixed in a macromolecule must proceed by this mechanism. Stryer and Haugland use the  $\alpha$ -naphthyl group as sensitizer and the dansyl group as emitter. These are attached at opposite ends of an oligoproline chain. A series of such sandwich molecules has been prepared, in which the length of the proline chain varies from one up to twelve residues. The advantage in using prolines as spacers is that at chain lengths greater than five a rigid helical structure (polyproline II helix) is formed, so that the separation of the two chromophores is always more or less precisely fixed. Further, the complete depolarization of the dansyl fluorescence in these compounds, when observed in a rigid glass matrix, shows that the chromophore is freely rotating; consequently there are no complications from differences in the relative orientation of the chromophores (since the efficiency of transfer depends also on the angle between the two transition dipoles).

The extent of energy transfer is determined from the excitation spectrum: the intensity of fluorescence from the dansyl group is measured with varying excitation wavelength. If there is no energy transfer, the excitation profile simply follows the absorption spectrum of the dansyl group, whereas for complete transfer it follows in effect the sum of the absorption spectra of sensitizer and emitter.

From the crystallographic dimensions of the polyproline II helix one can determine the separation of the two chromophores for each compound in the series, and it is found that the extent of energy transfer falls from 100 per cent when one proline residue separates the chromophores to 16 per cent when there are twelve prolines; moreover, it is found that the  $r^{-6}$ -law holds with remarkable precision (an exponent of 5.9 is found). This is a pleasing result, for it provides the most conclusive evidence yet in favour of the Förster theory.

Stryer and Haugland refer to these measurements of energy transfer as a function of distance as a spectroscopic ruler, and indeed the method holds out the promise of applications to biological molecules. There are many systems in which there is a possibility of attaching a sensitizer and an emitter at functional sites on a macromolecule or assemblage of molecules so as to determine their separation. Whether such an elegant approach is in practice too good to be true—at least as far as more complex systems are concerned—will remain to be seen, but there is no shortage of applications that come to mind.

# Further Education in Australia

by

I. W. WARK

Commonwealth Advisory Committee on  
Advanced Education,  
c/o Department of Education and Science,  
P.O. Box 826, Canberra City, A.C.T.

In Britain there has been a movement (frustrated by Mr Anthony Crosland's decision to establish polytechnics) to abandon the binary system of higher education. Dr Wark, who is Chairman of the Commonwealth Advisory Committee on Advanced Education, believes that the binary system should stay. What follows is derived from an address by Dr Wark to the Australia and New Zealand Association for the Advancement of Science earlier this year.

THE Government of Australia set up a committee in 1961 under the chairmanship of Sir Leslie Martin, to report on tertiary education in Australia. This committee strongly advocated the development of institutions differing in outlook from universities, to train and educate people for various professions. It was felt that these would mainly develop from existing colleges. The Commonwealth Government, and the States too, have wholeheartedly accepted this main theme of the Report. It was, indeed, time they did so. During the years 1947 to 1962, the share for the technical colleges of the total money available for tertiary education dropped from twelve to seven per cent, while their percentage of the total tertiary student pool rose from thirty-four to thirty-seven per cent. They were merely marking time.

To facilitate the development of these colleges of advanced education, the Commonwealth Advisory Committee was set up under my chairmanship. Our first report, submitted in June 1966, has been accepted almost in full by the Commonwealth and State Governments. While this report has been circulated fairly freely in educational circles in Australia, there are one or two aspects of it which I think should be emphasized today. It is insisted by the States that, while the emphasis should be on training for a particular vocation or profession, the colleges must also impart a broad education. This is essential in the present-day world, for the average student can expect to have to change his vocation at least once, and possibly many times, during the course of his working life. Our colleges must aim to produce engineers who are more than engineers and accountants who are more than accountants. Throughout life there are very limited numbers of opportunities for the determined specialist, except within the universities where he is undoubtedly needed.

I would like to feel that Australia will benefit from Great Britain's mistake, conceded now on many sides, of having converted first-class institutes of technology into universities. Fortunately, some of them seem determined to remain true to their former selves, but already others are said to be striving to emulate older universities.

I know that some Australian institutions have had the ambition to be recognized as universities, but to me it seems obvious that were this achieved, they could hardly expect to be ranked with the major universities of this country, at least for a very long time to come. I therefore greatly admire the decision of the Council of the South Australian Institute of Technology, which for many years has trained students for certain degrees of the University of Adelaide, to restrict its activities from 1970 onwards to the training of students for its own awards.

My Committee has repeatedly stressed that the students of universities and colleges will, in general, be different, but that neither should be regarded as superior or inferior. In our report we draw a comparison between the two types of institution and the two types of students. In the colleges there would be:

- (a) A greater concentration on part-time studies associated with employment, especially in scientific fields.
- (b) An emphasis on applied rather than theoretical work.
- (c) A more direct and intimate relationship with industry.

(d) Far less attention to post-graduate training and research.

(e) A primary emphasis on teaching.

Whereas in a university the subject is all-important, in industry the problem transcends the subject or discipline. The recruit to a technical company must be prepared to devote his whole attention to some problem, even though it takes him away from his original interests and into neighbouring disciplines.

Armstrong, Hill and Ross found that ninety per cent of the Ph.D. graduates in chemistry in Australia wanted in their next year to go on dealing with the problem of their last year of formal training. Ninety per cent! It is appalling. Their Ph.D. studies have evidently failed to develop a spirit of adventure, a desire to accept a challenge such as industry presents. Are the professors to blame? Are the students themselves so timid that the training money has been wasted on them? Or is industry to blame for not having sold its challenge?

In New South Wales an attempt was made to abandon the binary system of higher education, and the diploma courses of the old Sydney Technical College were absorbed into the University of New South Wales. Judging by the reaction of the employers, this experiment was no great success, and new courses at New South Wales Institute of Technology are now being established to replace the diploma courses of the Technical College.

Following the recommendations of the Martin Committee, Australian universities have been happy to support the development of the new colleges, thinking that their own problems will become intolerable if the colleges are not developed rapidly. It would be helpful, I think, if leaders of industry were to make public their views in this matter. My Committee has found them to be wholeheartedly behind the scheme, but they have not been as outspoken as we would have liked.

Because of their emphasis on teaching rather than research, colleges can at present train men and women at perhaps two-thirds the cost of university training, and probably do a better job for the type of student for which they cater. As the colleges develop specialities associated with particular industries, however, the difference in cost will lessen. Twenty years from now it seems that there will be more students in the colleges than in the universities, which will become still less committed to vocational courses and more interested in advancing scholarship.

In Australia, the forgotten man in all the main educational discussions is now the technician. I use the term technician in a general sense, to include the non-commissioned but highly skilled officers who serve in technology, commerce, public health, librarianship, music, art, and so forth. Without them, however talented the leaders might be, industry would grind to a halt.

There are two main ways of becoming a technician. One involves a two-year, tertiary level, full-time course, or its equivalent part-time. The other is via "failed diploma" or "failed B.Sc.". Each route produces worthwhile technicians, though the latter lack any specific qualification and suffer thereby, at least at the outset. I used to laugh at the old story of the Indian who cited as

a qualification, "Failed B.A."; I no longer do so. The first method will yield ten to twenty per cent of qualified men who could with advantage continue with study: at present, through close adherence to prescribed standards, we make it too difficult for them.

Other countries take much interest in the training of technicians. In a recent visit to the USA I called at the Wentworth Institute in Boston, which confines itself to technician training. This is a most impressive college—perhaps the most impressive of its type in that country. The courses are designed to produce men for industry: they do so with the co-operation of industry. Industry may itself impart a training to quite high levels; trainees lacking formal qualifications may find themselves "leg-roped" to a particular company.

At Breukelen, in Holland, I visited a commercial college where a residential course runs for two years from approximately matriculation level. The aim is to produce men with a knowledge of the techniques required for export business, upon which the livelihood of Holland depends. A thorough grounding is given in the commercial side of several European languages—English, German and French—for it is considered that unless you know the language of the country with which you are trading, and you know it to perfection, you will have difficulties, and you will lose to a competitor with a better technique. There are 150 students graduating from this residential college each year, and more than 300 positions are available for them throughout the world.

At the Hague, I visited one of thirty of Holland's senior technical colleges, where the aim is to produce a sub-professional engineer—or superior technician. Students attend college for two years after secondary schooling followed by one year's training in industry, and a final year back in the college. Post diploma night courses, taken by half the students, close the gap with the professional engineer.

At the other end of the spectrum is a very advanced commercial college, the Management Development Institute, in Geneva. This was brought into existence by

Nestlé in close co-operation with the Harvard Business School. Age of entry is between thirty and forty years. Appropriate formal education and business experience are prerequisites for admission. The course is an intensive one of nine months, and it is expected that the sponsoring company of a student will support him during this period and pay his fees. These cover about 90 per cent of the cost, and the deficit is borne by the Nestlé Company which each year provides some six or eight students out of the total of fifty. There is no government subsidy, no control except through the Harvard Business School, and the language spoken is English.

I have a feeling that more Australians should attend these two schools, and that Australia should be represented much more strongly in the queue for the students from Breukelen, many of whom emigrate. They are given no formal qualification whatever, which is perhaps the reason why we are unduly suspicious about employing them.

During my life I have come to have a very high regard for those who accept leadership in industry, commerce, government and community services; for those who make the decisions and judgments affecting us all; for the men in charge of production, of the health of the nation, of our own financial policies and international relationships. Too often they are criticized, even scoffed at, by intellectuals who could with benefit go humbly before them for a sharpening of their own outlook and a broadening of their education.

This brings me to my main conclusion: that industry has been and always will be a most important source of training for service within industry. This training, however, must be supplemented at one time or another by first-class courses, conducted within colleges or universities, by men and women with a close knowledge of their own subject and also of what industry needs.

Behind all this is the need for new discoveries, new knowledge, on which to build. These will come from fertile and adventurous minds engaged in research, whether in educational establishments or in industry.

## Testing Sonic Booms

by  
RODNEY CLARK

The British summer has been disturbed on one or two occasions by tests of aircraft at supersonic speeds. In the United States there is more experience.

IN July 1967 the United States National Sonic Boom Evaluation Office published an interim report on the sonic boom experiments at Edwards Air Force Base by Stanford Research Institute. One of three types of supersonic aircraft—the *F104*, the *B58* and the *XB70*—was flown over Edwards AFB between three and eight times a day for four years. Most of the aircraft were flown directly over the testing site at constant supersonic speed. The aircraft then slowed to turn at subsonic speed.

One series of experiments was concerned with the effect of booms on people living in houses typical of the American west, constructed mainly of wood, air conditioned, with the windows closed. Booms heard outdoors were found to be slightly less tolerable than those heard indoors, but "it is possible that sonic boom and house will interact in such a way that the interference effects on human beings are aggravated more than other externally generated noises". Particular rooms which magnified the booms did not necessarily magnify the sound of subsonic aircraft. The subjective unpleasantness of the booms increased faster than their intensity. A peak overpressure of

1.69 lb/ft<sup>2</sup> from a *B58* was considered almost intolerable by 27 per cent of the residents of Edwards, and by 40 per cent of the inhabitants of the towns of Fontana and Redlands, which were not near the flight path of supersonic aircraft. There seemed to be little difference in the response of the subjects to booms of equal overpressure caused by the three aircraft, despite the much longer duration of the "signature" of the boom of larger aircraft. When heard indoors, the boom from the *XB70* was least tolerable, but out of doors it was the *B58* that was the greatest nuisance.

It was possible to compare the subjective effects of booms and the noise of subsonic aircraft. People were more sensitive to the former, and could distinguish between booms differing by only 1 dB overpressure. According to this report, it was not possible to say which of two aircraft sounds was the loudest when they differed by less than 2 dB. 71 per cent of the residents of the area considered that sonic booms were the most intolerable noise to which they were subjected. There was, however, no indication of any effect on farm animals, perhaps, th-

report suggests, because they had become adapted to the noise.

It was confirmed that atmospheric conditions within two thousand feet of the ground contribute most towards the variability of the booms. How booms affect structures has not yet been analysed in detail, but little damage could, apparently, be definitely attributed to them. Altogether 57 complaints were received, most of them concerning glass, but investigations showed that only three panes out of more than 100,000 had definitely been cracked by supersonic aircraft. This represented a rate of one window pane broken for between 780,000 and 1,300,000 panes exposed to booms. (If this proportion seems low, it is worth remembering that more than a hundred million panes of glass might be exposed to each supersonic aircraft flying over London.) No seismic effects that might cause damage in mines were observed.

Most of the conclusions of the report are in agreement with theoretical predictions, and its authors enter into no speculation about what life will be like under the flight path of supersonic airliners. The effects of a boom could be expected to be extreme at some points on the ground if the boom was caused by an aircraft which was accelerating and turning. These conditions were avoided in most of the tests, but in one series of flights, an F106 was flown in "porpoising" flight. These movements were shown not to contribute to the features of the boom measured on the ground, but the report remarks "that a larger airplane has a sonic boom that depends relatively more on its lift, so motions of a SST (supersonic transport) in flight may still lead to significant variations in the sonic boom". Booms can be magnified several times by reflections off surfaces of courtyards, rooms, or narrow streets. This was not investigated in the experiments; the test houses were widely spaced, and although tests were carried out on a long building, a bowling alley, none of the buildings in which instruments were placed could be described as tall. It follows that even if the results give some slight indication of the effect of supersonic aircraft on small towns in the western United States, they will be of very little practical use to planners in Britain.

In Britain, however, despite the fact that Concord will fly in six months time, only eleven tests have been conducted by the Ministry of Technology. It is difficult to see how any information can have been derived about so complex a phenomenon from so small a number of experiments. In any case, it appears that few of those working on the psychological and structural effects of

supersonic aircraft actually assisted at the experiments. Owing, in part, to the ban on supersonic flights over Britain, little practical research has been done into the effect of booms on people and buildings. Although it was long ago shown, in tests with the Fairey Delta II, that resonance to booms might be hazardous<sup>1</sup>, there is at present no programme of experiments into the subject although a good deal of theoretical analysis has been done by a team under Professor E. J. Richards at the University of Southampton. The Building Research Station investigates complaints of structural damage allegedly caused by supersonic aircraft.

British psychologists have had only limited benefit from the vast number of American experimental booms, over Oklahoma City, White Sands and, now, Edwards. And the small amount of research done in Britain confirms that there may be differences between relevant conditions in Britain and America. It seems, for example, that sonic booms are less bearable in British houses than outside them (Johnson, D. R., and Robinson, D. W., *Acustica*, 18, 241; 1967).

Table 1. AIRCRAFT USED IN SONIC BOOM TESTS

	Wingspan (ft)	Length (ft)	Weight (lb)
F104(S)	22	54	31,000
B58	56	96	160,000
XB70	105	185	530,000
F106	38	71	38,000
Lightning	34	55	50,000
Supersonic transports			
Concord	84	185	330,000
Boeing 2707	174	306	675,000

The American tests, extensive though they have been, have not been comprehensive—no great, densely packed metropolis has been subjected to sonic booms day and night. And even if it were possible to draw valid conclusions from them, there is little to indicate that they would be relevant to Britain. Nevertheless, the British government has not yet said that there will be further tests, nor has it given any indication that the full results of the recent series will be published. It would seem that the Concord will be flying long before there is justification for the remark of Mr E. Dell, lately Joint Parliamentary Secretary to the Ministry of Technology, who said "We have achieved the object of informing people about the nature of a supersonic bang".

The Seabird Group,  
c/o British Ornithologists' Union,  
The Bird Room,  
British Museum (Natural History),  
London

G. R. POTTS

Department of Zoology,  
University of Durham

The Torrey Canyon disaster probably killed more than 30,000 seabirds. In a sample of 1,223 dead birds of eight different species 97 per cent were guillemots and razorbills.

OIL pollution at sea has been a growing hazard to birds since the beginning of the century. Since the First World War the Royal Society for the Protection of Birds has carried out intermittent surveys of bodies on beaches to assess the damage, and, since the Second, the International

Council for Bird Preservation has played a leading part in agitation for the control of oil pollution<sup>1</sup>. While the general character of the damage has long been known, there has been less information on the origin and age of the birds affected. Following the success of thirty years of

beach patrolling in adding to the knowledge of the birds of New Zealand and their mortality<sup>2</sup>, and a preliminary survey of a pollution incident on the north-east coast of England early in 1966 which yielded new information on the composition of the wintering auk population<sup>3</sup>, when the RSPB launched a further beach survey in the winter of 1966-67 the Seabird Group also asked for more detailed information on the bodies found.

It would have been best to have whole bodies for identification, and failing these heads might have been the most useful item, for they commonly show the greatest variation with race, age, sex and season, but neither of these is easy to handle in bulk, so we asked for one wing from each bird. Only a small number, useful principally for comparative purposes, were collected along the east and south coasts of Britain during the winter months. Larger numbers were not received until the tanker Torrey Canyon was wrecked on the Seven Stones rocks off Cornwall on March 18, 1967, and the animal protection organizations agreed to send us a wing from each dead bird that they handled. We received 1,223 wings from south-west Britain during the months following the wreck

### Numbers and Species Killed

In our sample nearly 98 per cent were wings of the larger auks—guillemots and razorbills—with six other species comprising the other 2 per cent (Table 1). Although the relative proportions of guillemots and razorbills killed showed local geographic variations<sup>4</sup>, the ratio of these two species in the sample is very close to that in the much larger sample of 7,851 birds sent to the Cornish cleaning centres<sup>5</sup>. In France, however, in a small sample the ratio was reversed<sup>6</sup> with about 75 per cent razorbills and 25 per cent guillemots (Table 2).

Table 1. CLASSIFICATION OF BIRD WINGS RECEIVED AFTER THE TORREY CANYON DISASTER

Species	Number	Length (range and mean in mm)	Proportion (per cent)
Guillemot <i>Uria aalge</i>	957	(See Table 2)	78.2
Razorbill <i>Alca torda</i>	237	178-206 192.6	19.4
Shag <i>Phalacrocorax aristotelis</i>	20	255-276 163.7	1.6
Puffin <i>Fratercula arctica</i>	5	155-162 160.0	0.4
Great northern diver <i>Gavia immer</i>	1	(278: in moult)	0.1
Black-throated diver <i>Gavia arctica</i>	1	(229: in moult)	0.1
Cormorant <i>Phalacrocorax carbo</i>	1	307	0.1
Kittiwake <i>Rissa tridactyla</i>	1	308	0.1

Nearly all the birds at the Cornish cleaning centres died and so did about 2,000 sent to the French centres in Brittany. Hence the absolute minimum total kill was about 10,000 birds and after allowing for birds lost at sea and

Table 2. PROPORTIONS OF GUILLEMOTS AND RAZORBILLS FROM DIFFERENT LOCALITIES

	Guillemots		Razorbills		Total
Cornwall: early April	(No.)	(%)	(No.)	(%)	
Newquay	61	61	39	39	100
Mousehole	168	73	61	27	229
Truro (1)	173	82	39	18	212
Truro (2)	192	86	31	14	223
Truro (3)	85	94	5	6	90
Slapton	115	94	7	6	122
Miscellaneous	43	91	4	9	47
Total	837	82	186	18	1,023
Late April	68	72	28	28	96
May	52	69	23	31	75
Grand total, Britain	957	80	237	20	1,194
Perros Guirec, France <sup>6</sup>	110	22	390	78	500
Grand total	1,067	63	627	37	1,694

Note. All these places were cleansing stations for birds collected elsewhere, and the precise date and place of origin of each sample are uncertain, although there was clearly a difference in the proportion of guillemots to razorbills from place to place in Britain (possibly because razorbills died more rapidly before they were evacuated), and between Britain and France (where there were more razorbills). The proportion of razorbills also increased later in the season in Britain.

on inaccessible parts of the coast the full total is likely to be at least two or three times this figure, and could be anything up to ten times as large. Although small numbers of a few other species were killed, the species listed in Table 1 were those with an important mortality.

### Sub-species of the Guillemots

We were able to classify most of the guillemot wings into sub-species on the basis of colour and size. The upper parts of the race *U.a.albionis*, which breeds south of Central Scotland, are comparatively brown while the backs of birds breeding further north, the nominate race *U.a.aalge* from the Baltic, Scotland, Iceland and eastern North America, and the race *U.a.hyperborea* from the Barents Sea<sup>7</sup>, are darker. The two northern races can be distinguished from each other and from the southern race *U.a.albionis* by their size; *U.a.hyperborea* have larger wings than *U.a.aalge* and *U.a.albionis* although there is a wide range of overlap<sup>8</sup>.

Many of the wings we received were too dirty to assess, but the remainder after drying were compared with museum skins of adults obtained from breeding stations and wings collected on north-eastern beaches from Durham to Caithness (Table 3).

Table 3. WINGS OF GUILLEMOTS FROM THE BREEDING STATIONS AND BEACHES

Origin	No.	Wing length (range and mean in mm)	% of first year birds
Breeding stations			
England, Wales, Ireland ( <i>U.a.albionis</i> )	20	188-201	194.9
North Scotland and islands ( <i>U.a.aalge</i> )	20	193-206	200.0
Bear Island ( <i>U.a.hyperborea</i> )	7	204-216	210.0
Beaches			
Torrey Canyon, brown-backed (61%)	470	180-204	192.3
Torrey Canyon, black-backed (39%)	296	184-205, 215*	195.1
North-east coast, mainly dark	15	201-215	206.4
			(20)†

\* One exceptional bird of the race *U.a.hyperborea*.

† Ratio in 266 birds washed up in the spring of 1966 (ref. 3); only one, or 6.7 per cent, in the spring of 1967.

Table 3 shows nearly two-thirds of the birds killed in the Torrey Canyon disaster belonging to the southern race *U.a.albionis*, and most of the rest to the nominate race *U.a.aalge* from regions immediately to the north; one bird, however, was conspicuously larger than the others with a wing of 215 mm and it was probably of the Arctic race *U.a.hyperborea*. A number of birds from north-eastern English beaches were as large as this race in both 1966 (ref. 3) and 1967, and its occurrence there is further demonstrated by the recovery in Durham of a bird ringed near Murmansk<sup>9</sup>, but *U.a.hyperborea* has not been found so far south-west before. We examined the guillemot wings for evidence of the occurrence of the postulated race *U.a.spiloptera* of the Faroes, which is reported to have a heavily marked underwing<sup>10</sup>, but this type of underwing was found in approximately 10 per cent of birds of both the southern and nominate races. It has also been reported in several other populations<sup>11</sup>, so that this character alone does not seem very reliable.

A razorbill with a wing of 212 mm, which falls within the range of the northern nominate race *A.t.torda* of this species<sup>7</sup>, was seen in the Scillies during the Torrey Canyon disaster by J. L. F. Parslow, and birds of this race, ringed in the Murmansk area, have been recovered in Eas Lothian, Flint and Cornwall<sup>9</sup>, but this form was not detected in our sample of wings.

### Age Distribution

Guillemots in their first year appear to be distinguished by the pale base of the bill, the retention of faded inner primary coverts<sup>3</sup>, and the possession of pale edges to the longer under wing coverts. Only the last character, the

validity of which was confirmed by examination of a series of skins in the British Museum (Natural History) collection, was easily applicable for ageing our sample of wings. Twenty-nine per cent of the brown-backed and 48 per cent of the black-backed birds in the Torrey Canyon kill showed this first year character. In contrast, only 20 per cent of the birds examined on the north-east coast in the early spring of 1966 showed first year characters. There was also a small but consistent difference in the average size of first year and adult wings in our sample, the brown-backed averaging 192.3 and 193.7 mm and the black-backed ones 194.4 and 195.7 mm, respectively. Storer<sup>11</sup> reports a large increase in size with age in some populations, but possibly some of his young birds were autumn specimens which were not yet fully grown. Apart from the pale feather-edgings in first year birds there were no important differences in the amount of marking of the underwing between first year and adults in either the brown-backed or the black-backed populations.

About half the guillemot population fail to breed<sup>12</sup>, and pairs that do breed produce on average about 0.4 young annually<sup>13</sup>. At most therefore the proportion of yearlings at sea should not exceed the 20 per cent found off the north-east coast in the spring of 1966 (ref. 3), and indeed there was only one bird in fifteen, or 6.7 per cent, in 1967. Yet there were 29 per cent yearlings among the southern brown-backed birds in the Torrey Canyon kill, and 48 per cent among the northern black-backed ones. The explanation is probably that young birds are more migratory than adults<sup>14</sup>. While some local adults will have been killed in Cornwall, and some local yearlings may have been outside the area, they will have been replaced by immigrants including a high proportion of immatures from the larger populations to the north.

The twenty shag wings from the Torrey Canyon sample contained fully grown feathers, but showed an interesting mixture of plumages. The primary moult of this species usually begins with the inner (first) primary and progresses to the outer (eleventh) feather at the average rate of one every 22 days. The moult may occur between February and December, but mainly in the autumn, and in many shags the cycle is not completed in 1 year. In these cases the moult recommences the following year both at the previous growing-point and at the beginning again<sup>15</sup>. Consequently, it is possible to age shags by identifying the number of plumages present at any one time; the age of the Torrey Canyon birds is shown in Table 4.

Table 4. THE PLUMAGE AND AGE OF SHAGS FROM THE TORREY CANYON KILL

Plumage cycles present	Number	Cohort (note overlap)
Juvenal	1	I
Juvenal and post-juvenal	0	
Juvenal, post-juvenal and first nuptial	4	II
Post-juvenal and first nuptial	6	
Post-juvenal, first and second nuptial	2	III
Post-juvenal, first, second and third nuptial	1	
First nuptial	3	IV
Two nuptial	3	II+

It can be assumed for present purposes that the number of two and three-year-olds is 12; thus the age distribution of the present sample is first year, 1; second and third year, 12; and more than 3 years, 7. Yearlings should have been in the area at the time of the disaster<sup>16</sup>, and a full adults should have been nesting. From the mortality rates of this species<sup>15</sup> an expected age distribution can be drawn up: first year, 4; second and third year, 6; more than 3 years, 10. The difference between

what was observed and expected is significant ( $P \approx 0.01$ ). This unexpected composition of the age-groups of the shags might be explained by a different survival of past year-classes, but seems more likely to be due to differences in the extent to which the birds move around, and become susceptible to pollution, during the period when they start to prospect nest-sites. In this matter, as with others, more direct observation in the oiled areas would have been useful.

While all the other birds had fully grown flight feathers, the two divers, a great northern and a black-throated, were both in full wing-moult, with short, growing primaries. Many water-birds are known to lose their flight-feathers simultaneously<sup>17</sup>, so that they become flightless, but this usually occurs in the late summer. Only the larger divers postpone the main wing-moult until the spring<sup>18</sup>, and this has already caused a severe mortality from oil pollution on the New England coast<sup>19</sup>. It seems probable that the small part of the Cornish winter population of divers that was still in the area in March, completing the moult, was killed flightless in the water. Most of the divers would, however, have migrated north.

Oil is, potentially, an even greater danger to species like the auks when both adults and young are flightless on the water at the same time in late summer. The protracted moult of shags, however, spares them from this danger; of the shag wings we examined, most showed a two or three year moulting cycle (see Table 4) but one exceptional wing showed traces of a four year cycle. Remarkably, this bird would only renew its outer primary once in 4 years.

This survey clearly shows that the main bird mortality from the Torrey Canyon disaster involved local British populations, especially the larger auks, including disproportionately high numbers of the more migratory young birds. Some sub-adult shags, moving around in search of nest-sites, were also killed. We received only two specimens of northern birds, the great northern diver and the solitary northern auk *U. a. hyperborea*.

We are grateful for wings, a variety of assistance, and information from many organizations and individuals, including the Royal Society for the Prevention of Cruelty to Animals, John Nicholson and the Royal Society for the Protection of Birds, Messrs Robert Spencer and Henry Mayer-Gross of the British Trust for Ornithology, Messrs J. L. F. Parslow and N. R. Phillips, who later carried out breeding censuses for the Nature Conservancy, Dr C. J. F. Coombs and the Rev J. A. Beckerlegge of the Cornwall Bird-watching and Preservation Society, Dr G. M. Dunnet and Mr A. W. Diamond of the Natural History Department, Marischal College, University of Aberdeen, Messrs Tony Soper and Einar Brun, and Dr Finn Salomonsen. Dr Dunnet and Dr D. W. Snow commented on drafts of this note.

# New Syntheses of Porphyrins and Related Tetrapyrroles

by

A. H. JACKSON  
G. W. KENNERThe Robert Robinson Laboratories,  
University of Liverpool

Recently methods of synthesis of porphyrins have become more versatile. This makes available many new routes to biologically significant compounds.

NUMEROUS porphyrins were synthesized by Hans Fischer and his co-workers<sup>1</sup>, and these classical investigations established the structure of haem and many other porphyrins of natural origin. Fischer's syntheses, however, gave poor yields in complex cases and left considerable room for improvement. A notable advance was made by MacDonald<sup>2</sup>, who developed an elegant method employing pyrromethanes, which led to syntheses of all four coproporphyrins among others, and the same principle was incorporated in Woodward's brilliant total synthesis of chlorophyll<sup>3</sup>. More recently Fischer's route has also been significantly varied and extended by Johnson and his colleagues<sup>4-6</sup>. At the same time we have been developing quite different routes to porphyrins, and these now offer considerable scope for synthesis of compounds of biological significance.

The basic tenet of our programme has been that the porphyrin macrocycle should be formed from a well defined tetrapyrrolic compound, constructed logically from four separate pyrrole derivatives. Our initial studies<sup>7</sup> produced some new methods for linking pyrrole nuclei by methylene groups, after the pattern of biosynthesis from porphobilinogen, but it was soon apparent that stepwise synthesis of tetrapyrrolic compounds with three methylene links were beyond the scope of this approach. Such compounds are prone to cleavage by acids and other electrophiles, and therefore we turned to construction of tetrapyrrolic compounds stabilized by an internuclear carbonyl group, namely, the oxobilanes (for example, I).

Two syntheses through oxobilanes were devised<sup>8</sup> and about twenty different porphyrins have now been prepared (ten by each method). The first method involves *a*-oxobilanes and is described elsewhere in detail<sup>9</sup>. Examples of biologically important porphyrins which have been synthesized by this method include mesoporphyrin-IX (ref. 8) and coproporphyrins-III and -IV (unpublished work of Mr J. Wass). An important improvement in the general method is the recent use of  $\alpha$ -pentachlorophenyl- $\alpha'$ -benzylpyrromethane dicarboxylic ester as intermediates; the pentachlorophenyl esters can be selectively hydrolysed (or the benzyl esters selectively hydrogenolysed) to give the pyrromethane  $\alpha$ -carboxylic acids required in the *a*-oxobilane synthesis. Protoporphyrin-IX has now been synthesized by this route and also by the *b*-oxobilane method as described below<sup>10</sup>.

The *b*-oxobilane (Ia) was constructed from pyrrole units by essentially similar methods to those described elsewhere for analogous cases, and after removal of the protective benzyl ester groups by hydrogenolysis it was cyclized to the oxophlorin (IIa) with methylorthoformate in mildly acidic conditions. The oxo-group was removed (by acetylation, reduction and re-oxidation) to give the bis-acetoxyethylporphyrin (IIIa), and modification of the acetoxyethyl side-chains as indicated schematically below then afforded protoporphyrin-IX dimethyl ester (IIIb).

Another example of the use of the *b*-oxobilane method is the synthesis<sup>11</sup> of chlorocruoroporphyrin (IIIc) dimethyl ester which is derived from the haem of *Spirographis* *spa*.

*lanzanii*<sup>12</sup>. The bromo- $\alpha$ -oxobilane (Ib) gave the oxophlorin (IIb) and thus the porphyrin (IIIc) the acetoxyethyl group of which was transformed into chloroethyl as indicated already. The formyl group was introduced at the 2-position of the chloroethylporphyrin (IIIc) and then protected as the relatively stable neopentyl glycol acetal

during elimination of hydrogen chloride. This synthesis is of more general interest because chlorocruoroporphyrin contains two of the three sensitive substituents present in haem- $\alpha$ , that is, the formyl and vinyl groups. Haem- $\alpha$  is the prosthetic group of cytochrome oxidase and because its structure is still in doubt<sup>13</sup> (especially the precise nature of the long fatty side-chain) our new methods are clearly of potential use in a synthetic proof of structure.

The foregoing synthetic work has also clarified the structure of pemttoporphyrin, a recently isolated faecal metabolite<sup>14</sup> with one of the structures (III;  $R, R' = H$ ,  $-\text{CH}=\text{CH}_2$ ) (ref. 15). One isomer (III $f$ ) was made from the intermediate (IIIe) and the other (III $g$ ) in a separate synthesis by the  $\alpha$ -oxobilane route. The nuclear magnetic resonance spectra of the two isomers (in  $\text{CDCl}_3$ ) showed considerable differences, and that of the synthetic porphyrin (III $f$ ) is identical with that of pemttoporphyrin<sup>15</sup>.

The biosynthesis of chlorophyll from protoporphyrin-IX has been studied extensively in recent years and the work of Bogorad, O. T. G. Jones and others<sup>16</sup> has revealed much of the route. Our new syntheses of protoporphyrin permit, in principle, labelling with carbon-14 at various positions for biosynthetic studies, and a valuable possibility, which we have explored, is tritiation. The oxophlorin (IIa) undergoes specific exchange with tritiated acetic acid at the *meso*-position opposite the oxo-group (\* in the formula), whereas under more strongly acidic conditions no exchange occurs owing to formation of the dication. Protoporphyrin, specifically tritiated at the  $\delta$ -position, has now been prepared from this oxophlorin.

An outstanding problem in the biosynthesis of chlorophyll is the mode of formation of the so-called isocyclic ring, and we have suggested before<sup>17</sup> that this arises by oxidation of the 6-propionate group (originally present in protoporphyrin) to a  $\beta$ -keto-ester followed by cyclization at the  $\gamma$ -position, that is

We have accordingly synthesized (unpublished work of Mr T. T. Howarth) rhodoporphyrin-XV dimethyl ester (IVa) by the  $\alpha$ -oxobilane route and elaborated the 6- $\beta$ -ketoester side-chain as shown in the scheme outlined below. The cyclization of this ester *in vitro* is currently being investigated, and synthesis of the 2,4-divinyl analogue (which would be the biosynthetic intermediate) is planned. An alternative pathway for the formation of the isocyclic ring may also be envisaged involving a 6-acrylic ester group ( $\text{CH}=\text{CH}-\text{CO}_2\text{Me}$ ) (compare chlorophyll- $c$  which has recently been shown to contain an acrylic ester side-chain at the 7-position<sup>18</sup>); such compounds should be readily accessible by a variant of our new methods.

Oxophlorins (or "oxyporphyrins" as they were originally named) have been known for nearly thirty years, and were originally prepared by non-specific oxidation of porphyrin iron complexes<sup>19-24</sup>. We prefer the name oxophlorins because extensive spectroscopic observations<sup>25</sup> have clearly shown that the *meso* oxygen function is present as an oxo-group in both the free base and the mono-cation (which is protonated on nitrogen). For purposes of nomenclature, however, it is convenient to regard oxophlorins as derivatives of the tautomeric hydroxy porphyrin.

Oxophlorins are of considerable biochemical interest because they (or rather their iron complexes) may be intermediates in the catabolism of haem to bile pigments. Indeed, the "oxyporphyrins" originally prepared<sup>19-24</sup> by Fischer and Libowitsky, and by Lemberg have been converted *in vitro* into bile pigments, and we have con-

firmed these earlier studies by showing that "β-oxymesoporphyrin-IX dimethyl ester" (V) gives glaucobilin-IX-β dimethyl ester (VI) in good overall yield. In this connexion we have recently synthesized "α-oxymesoporphyrin-IX", and the preparation of "α-oxyporphyrin-IX" is well in hand; we intend to study their conversion into bile pigments both *in vitro* and *in vivo*.

All this work has been greatly aided by extensive use of spectroscopic methods. Mass spectrometry is particularly suited to determinations with the small quantities of material available in structural studies (or in "pilot" preparations of porphyrins) and the relatively high stability of the macrocyclic porphyrin nucleus makes observation of the molecular ion nearly always possible<sup>27</sup>. A drawback of the method is that it gives very little information about the precise arrangement of substituents around the periphery of the ring, but this is to some extent remedied by careful studies of the nuclear magnetic resonance spectra<sup>28,29</sup> (as well as by biogenetic speculation).

We have also studied extensively the mass spectra of open-chain mono-, di-, tri- and tetra-pyrrolic compounds<sup>30</sup> and further work is in progress, especially on bile pigments where there is a number of unsolved structural problems. Interpretation of the spectra of urobilinoid compounds<sup>31</sup> is complicated by some unusual hydrogen transfers (or migrations), but recent work (unpublished, by Jackson, Murray, O'hEocha and Smith) has confirmed that the urobilin obtained by catalytic reduction of phycoerythrobilin<sup>32</sup> is structurally very similar to mammalian urobilins.

We hope to synthesize a number of model compounds for further mass spectrometry, both by ring opening of oxophlorins and by synthesis from some of the dipyrrolic intermediates we have used in our syntheses of oxobilanes.

This work was supported in part by the Nuffield Foundation.

## Food and Activity in the Mole *Talpa europaea*

by

KENNETH MELLANBY

Monks Wood Experimental Station,  
Huntingdon

Moles may be much less active and voracious than is commonly believed. This explains their ability to colonize infertile soils with little fauna.

THE commonly accepted view of moles is that they are "very voracious, consuming more than their own weight of food every 24 h; their whole life is an incessant hunt for food, only short intervals of repose punctuating

their nearly continuous feverish activity"<sup>1</sup>. It has been said that moles can only find enough food in habitats like deciduous woodland and old grassland which have a rich soil fauna<sup>2</sup>. Nevertheless we do find them in the

dry sandy soil of the East Anglian Breck, and at more than 600 m above sea level in the Pennines; in both these habitats soil animals, particularly earthworms, are far from abundant.

Many of those who have tried, unsuccessfully, to keep a mole in captivity have had these views on feeding and activity reinforced. A mole has been put in a box of soil; it has burrowed vigorously and continuously for a few hours and then died. Nevertheless, moles are easily kept alive and healthy for quite long periods, and with comparatively modest amounts of food.

A newly caught mole is probably starving; it may have been active for some hours and it is in a strange environment. The essential first step is to persuade it to feed. Although captive moles may be maintained on many articles of food, including liver, baby mice, mealworms and maggots, they always seem to prefer earthworms, particularly large *Lumbricus terrestris*. Newly caught moles often refuse any other type of food; if they are offered some three large worms (a large *L. terrestris* weighs about 5 g) they will probably consume these in a matter of minutes. They will then explore their surroundings and if a small box containing hay is present they will crawl in and go to sleep. They will probably sleep for at least 4 h, possibly for up to 7 h, and when they awake they will be, to all intents and purposes, domesticated and suitable subjects for further study.

Moles have been kept successfully in various types of container. Some workers have used a nest box connected to runs made of wire mesh; this has allowed behaviour to be studied over long periods<sup>3</sup>. Others, however, have found simple wooden boxes reasonably satisfactory<sup>4,5</sup>. Some have filled these with soil, but this becomes foul, and must be changed frequently. Wooden boxes, empty except for a small amount of hay or straw to make a nest, have also been used. I have used a wooden box, 60 × 35 cm, and 25 cm deep, with a wooden lid fixed over half the top, and a movable glass plate—to allow the animal to be watched—covering the rest. In the bottom I put "bulb fibre", about 2 cm deep. This contains some charcoal, which absorbs excretory products without quickly becoming foul. A small box 15 × 11 × 10 cm, with an entry hole, fixed at one end of the larger box and filled with hay, serves as a nest.

Moles do sometimes eat large quantities of food, but "more than their own weight every 24 h" is an exaggeration. I have made some experiments to determine the maximum amount of food taken. The box described was balanced so that it moved when the mole came out of the nest. This movement made an electric contact and rang a bell. Each time the bell rang, the mole was offered as many earthworms as it would eat; any not immediately devoured were removed. The total consumption in five periods of 24 h was 47, 51, 47, 54, 46 g (mean 49 g); the weight of the mole varied between 87 and 102 g during this period. This means that the food taken was just about half the body weight. However, even this is an over-estimate. The mole was frequently weighed just before and after feeding, and the gain in weight was always less than the weight of worms. Thus if 15 g of worms were taken, the gain in weight might only be about 12 g. This difference was not caused by excretion, for when the mole was fed standing on a clean piece of paper no substantial micturition or defaecation was detected. Parts of the worm, particularly the gut, which contained soil, were discarded.

Larger quantities of worms than can be eaten at once provoke an interesting reaction. Moles usually run a worm through their front feet until they reach the head end, and this is eaten first. When the mole is "full", it still bites off the head, but then it plays with the worm and usually buries it in the corner of the box. In the field caches of worms, with their heads bitten off, are sometimes found<sup>6</sup>; these are presumably worms buried by a satiated

mole. This habit of storing surplus food has caused some observers to over-estimate food consumption, because caches are easily overlooked.

Previous workers have shown that moles fed on insect larvae, which have a high calorific value compared with earthworms, can be kept alive when given 20–30 g/day<sup>7</sup>. These are probably maximum figures. I have never been able to make a captive mole take more than about 20 g of mealworms in 24 h. Incidentally when mealworms are eaten, the weight gained is generally slightly higher than the weight of the mealworms, probably because some soil is accidentally ingested at the same time. Surplus mealworms may, like earthworms, be cached, but the mole does not immobilize them and they may crawl away and escape.

Captive moles readily drink water, except when fed on an unlimited diet of earthworms, which contain at least 85 per cent of water and so presumably supply all requirements. In many natural situations, particularly under dry conditions where worms are scarce, moles must seldom have the opportunity to drink. Nevertheless, their reaction to water is so positive that drinking appears to be a frequent and normal activity. If a dish of water is placed near a thirsty mole it is soon found, and the animal drinks rapidly, taking as much as 10 ml. in under 5 min. If a mole fills its stomach with water, it may retire to its nest to sleep, but instead of remaining dormant for several hours it usually comes out again in less than an hour and will then take food as if completely unfed.

It is usual in studies of animal nutrition to note changes in body weight, and to assume that if this remains constant then an adequate diet is being given. Care must, however, be taken in interpreting gross body weights, particularly in animals like moles which can take meals which may be nearly 20 per cent of their starving weight. A starving mole may take up food (and water) and increase by as much as 15 g (for example, from 87 to 102 g). Thus only weights of animals in a similar state of repletion should be compared. Except in experiments when moles have been fed "on demand", I have compared weights of hungry animals with their stomachs empty of food, because these are basic measurements of the living tissues of the animals. A fall in the starving weight may mean a loss of reserves, as the result of tissue catabolism, or it may be the result of desiccation. In my experiments, I found only comparatively small changes in the starving weight of adult moles, whatever the diet administered. The effects of reduced intake of food were studied together with measurements of the activity of the animals.

Wild moles have been caught, fitted with radioactive cobalt tail rings, and after liberation their subterranean activity has been followed by means of a Geiger counter<sup>8</sup>. In this way it has been established that they have periods of inactivity, when they sleep in their nests, followed by periods of activity, when they travel along their burrows and dig new tunnels. This activity pattern is repeated about three times a day. There does not seem to be any regular rhythm, and the lengths of the rest and active periods are by no means constant. Thus there is no particular hour when a mole is most likely to be active or asleep. Nevertheless there are usually three periods of sleep, of between 3 and 5 hours, and three periods of activity, of roughly the same duration, every 24 h. The technique using radioactive tail rings has enabled much to be learned about mole activity, but it has limitations. The mole cannot actually be watched—lateral movement only can be detected—and its food consumption cannot be studied.

In my experiments in which the mole rang a bell when it left its nest, it was seen that a captive animal had a behaviour pattern on the same lines as had been demonstrated in the field; the mole slept for half the 24 h and usually took this sleep in three main periods. In order to study activity in more detail, and to allow the observer an unbroken night's rest, a simple actograph was con-

structed. A pen was fitted to the box, recording its movements on a revolving drum. Characteristic records are reproduced in Fig. 1. The first and last traces record behaviour when unlimited food, either earthworms or liver, was available. The second and third traces are from a starving mole. These and other records show a very striking similarity to the activity records of wild moles obtained using radioactive tail rings. They suggest that moles do not have an accurate internal "clock" and that, as the periods of activity and sleep are not always the same length, either type of behaviour may be found at any hour. They all show that long periods are spent in sleep. Most interesting, they show that starving moles are not more active than those which are fed. It appears that when a mole wakes up it has a period of activity, when it searches for food. If this is readily found the mole may go back to its nest and have a "nap", but it seems usually to come out again after perhaps half an hour, and not to enter a long (more than 3 h) sleep period until the end of a "normal" period of activity. On the other hand, if no food is found, searching goes on for some 3 h or so, and then the mole, still hungry, goes back to the nest and sleeps for at least 4 h. At the end of 24 h of starvation moles were found to have lost only about 5 g in weight, and they fully recovered this if allowed unlimited access to earthworms for a further day. I have not starved a mole for more than 24 h, but these results suggest that it might well survive for several days without food, though others have reported deaths in 48 h when feeding of captive moles was overlooked during weekends. Certainly there was no appreciable decrease in body weight when only between 5 and 10 g of food, which included worms and insect larvae, was provided in experiments lasting up to 14 days.

escaped into a paved area in my garden. There were pockets of earth, into which the animal burrowed, uprooting alpine plants and bulbs. Very little animal food was present, and over a period of a week the mole kept coming to the surface and exploring another soil pocket, coming up and down many times in one day. During this week it cannot have had a daily ration of as much as 10 g. Incidentally it still had its periods of sleep, between its largely fruitless searches for food.

These observations on feeding and activity may throw some light on the normal behaviour of wild moles. It has always been a mystery how these animals survive in soils with a poor fauna. If they can in fact exist on as little as 5 g of food, instead of 100 g or more assumed by some workers, the situation is easier to understand.

The observation that a starving mole spends much of its time asleep fits in well with field observations. It is not always realized that the mole's tunnel system is essentially a "pit-fall trap", and that digging is done to enlarge this system rather than to catch food<sup>1a</sup>. In soil with plenty of food, moles may do little or no digging for months at a time, and tunnels remain patent, used by successive generations, for many years. In poor soils, with little fauna, moles may need very much larger systems of burrows; these may be continually enlarged, and the effects on the vegetation, where annual plants easily colonize the fresh earth, will be consequently much greater. A mole, on waking, runs through its burrow system, feeding on the worms and other animals it finds. If it has been active for several hours, and, although it has only obtained a partial meal, it can find little more food, then further activity will be a waste of energy. By sleeping the mole reduces its metabolic rate, conserves its

Fig. 1. Behaviour of moles under different feeding regimes. The black rectangles indicate activity, the base lines show when the animals were asleep. *a*, Unlimited earthworms; *b* and *c*, starved; *d*, unlimited liver.

Moles do not live entirely underground. Young animals, in spring and early summer, leave the maternal burrow and move overground to fresh territory. Here they may enter existing old burrow systems, or they may excavate new tunnels, but during the summer their runs are often very superficial, scarcely going below the mat of the vegetation. This is where much animal life is found, except in very dry conditions. In a severe drought they have been found living even more superficially<sup>9</sup>, apparently unable to burrow in hard earth, which must contain few worms in the superficial layers. Moles also come to the surface when burrowing conditions are difficult and food is absent. This was demonstrated when one animal

energy, and gives time for more food animals to enter the burrows to be consumed in the next round of activity.

# Visual Pigments of Crayfish

by  
GEORGE WALD

Biological Laboratories of Harvard University,  
Cambridge, Massachusetts, and  
Marine Biological Laboratory,  
Woods Hole, Massachusetts

Crayfish eye extracts contain two visual pigments resembling in spectrum vertebrate rhodopsin and iodopsin. In these crayfish, as in primates, the "iodopsin" appears to be the red sensitive pigment of colour vision.

I HAVE found that the eyes of the common northern crayfish, *Orconectes* (then *Cambarus*) *virilis*, contain vitamin A<sub>1</sub> (retinol<sub>1</sub>) and that the destruction of its visual pigment releases retinal<sub>1</sub> (retinene<sub>1</sub>)<sup>1,2</sup>. Since 1943 not only has the name of the crayfish changed—as is usual—but so have the names of the molecules. Vitamin A<sub>1</sub> and retinene<sub>1</sub> have become retinol and retinal<sub>1</sub>; and vitamin A<sub>2</sub> and retinene<sub>2</sub> have now the formal names 3,4-dehydroretinol and retinal<sub>2</sub>. This was of some interest because, although terrestrial and marine vertebrates and several marine invertebrates characteristically possess visual pigments based on vitamin A<sub>1</sub> and retinal<sub>1</sub>, those of freshwater vertebrates are as characteristically based on vitamin A<sub>2</sub> and retinal<sub>2</sub>. No invertebrate is yet known which normally contains vitamin A<sub>2</sub>.

Dark adapted eyes of this crayfish, dried by grinding with anhydrous sodium sulphate and extracted in the dark with petroleum ether, yielded vitamin A<sub>1</sub> (Fig. 1a). Re-extraction with petroleum ether in bright light yielded

only a little more vitamin A<sub>1</sub>, apparently a residue left over from the dark extraction (Fig. 1a); although the same treatment of vertebrate retinas would have yielded a large amount of retinal<sub>1</sub>, released by the bleaching of visual pigment by the light. The extraction of crayfish eyes in light or darkness with chloroform, however, which denatures all known visual pigments, yields retinal<sub>1</sub> (Fig. 1b).

It seemed probable that the eye of the crayfish contains a visual pigment with retinal<sub>1</sub> as its chromophore, but that unlike vertebrate rhodopsin this does not yield its retinal to petroleum ether on exposure to light. This behaviour has since become familiar. A number of invertebrate rhodopsins (lobster<sup>3</sup>, *Limulus*<sup>4</sup>, grapsoid crabs<sup>5</sup>, squid<sup>6</sup>, cuttlefish and octopus<sup>7</sup>) bleach in the light only to metarhodopsins, which release retinal only very slowly and in circumstances that either denature the protein, such as here, or competitively remove it with hydroxylamine to form retinal oxime<sup>3-7</sup>.

Kennedy and Bruno found the visual sensitivity of the southern swamp crayfish, *Procambarus clarkii*, to be maximal near 570 mμ. They pointed out that this lies farther towards the red than all known rhodopsins, and resembles in spectrum the pigment of the vertebrate cone, iodopsin. They suggested that this displacement of visual sensitivity toward the red represents a general adaptation, common to both vertebrates and invertebrates, to life in relatively turbid freshwater environments, with their poor transmission of short wavelength radiation.

This observation led me to attempt to extract a visual pigment from the crayfish eye, and surprisingly my extracts contained at least two such pigments, whether taken from eyes of the swamp crayfish<sup>8</sup> or the northern crayfish from which I had earlier extracted vitamin A<sub>1</sub> and retinal<sub>1</sub> (ref. 9). This led in turn to an electrophysiological examination of the spectral sensitivities of these and other arthropod eyes<sup>10</sup>. Both crayfishes seem to possess apparatus well adapted for two colour vision, based on a blue sensitive and a red sensitive receptor system. In each of these animals the most important visual pigment extracted from the eye seems to be that of the red sensitive receptor. No visual function has yet been found for the minor pigments extracted from these eyes; nor, conversely, has the visual pigment of the blue receptor been identified in extracts.

The procedures were usually the same as those employed to isolate and extract rod and cone outer segment fragments from vertebrate retinas, on the tenuous ground that the rhabdomeres of invertebrate eyes look like the same type of structure, fortified by previous successes with squid, lobster and *Limulus*<sup>4</sup>. The structures which are isolated are composed largely of membranes, with a large content of phospholipid that makes them float in media in which other components of the eye tissues sink. With crayfish preparations large amounts of screening pigments that accompany the rhabdomere fraction must be removed. All the procedures were carried out in dim red light.

Whole eye stalks of dark adapted animals were ground in a mortar in M/15 phosphate buffer at pH 6.5. The

Fig. 1. Vitamin A and retinal from eyes of the common northern crayfish, *Orconectes virilis*. Absorption spectra of the blue products obtained by mixing extracts of the eyes with antimony chloride. The extraction of dark adapted eye tissues with petroleum ether yields vitamin A<sub>1</sub> alone (tall curve in a;  $\lambda_{\max}$  617 mμ; yield about 0.08 μg/eye). Re-extraction with petroleum ether in bright light yields only a little more vitamin A<sub>1</sub> (a, smaller curve). Extraction with chloroform, which denatures the visual pigment, releases retinal<sub>1</sub> (b;  $\lambda_{\max}$  664 mμ; yield about 0.09 μg/eye). All these extracts had also contained astaxanthin, which was removed by filtering in petroleum ether through calcium carbonate before performing the antimony chloride tests.

In all these properties the 510 m $\mu$  pigment strongly resembles vertebrate rhodopsin. Its yield, in terms of the absorbance at 510 m $\mu$ /100 eyes extracted into 1 ml. of digitonin solution and measured in a 1 cm layer, was 0.029.

A neutral extract of *Procambarus* eyes, exposed for 5 min to deep red light, yielded, as did the red sensitive pigment of *Orconectes*, a transient intermediate with similar properties. Recorded at 5.5–8 min after the start of irradiation, this displayed a difference spectrum, relative to the final product of bleaching, maximal at about 515 m $\mu$ , and with minima near 405 m $\mu$  and—rather unexpectedly—also in the red, near 620 m $\mu$ . Thereafter this pigment continued to bleach in the dark for at least an hour at 27° C. The difference spectrum shown in Fig. 3—the difference in absorption spectrum between the initial extract and the final product when red light produced no further change and all dark reactions were completed—has  $\lambda_{\max}$  about 556 m $\mu$ , and a minimum at about 392 m $\mu$  owing to retinal, either free or still combined with opsin in a meta-pigment. This is the chief pigment in these extracts, and in its difference spectrum, although not in its kinetics of bleaching, closely resembles vertebrate iodopsin. Its yield, in terms of the absorbance at 556 m $\mu$ /100 eyes extracted into 1 ml. of digitonin solution and measured in a 1 cm layer, was 0.059.

Subsequent exposure to yellow light, or long-continued exposure to the same red light, resulted in some further bleaching, maximal at about 525 m $\mu$ , and accompanied by a further rise in spectrum at about 390 m $\mu$  owing to retinal. The maximum bleaching in this case was only about one-third as great as that of the 556 m $\mu$  pigment, and the difference spectrum was not highly reproducible in detail. No intermediates of bleaching were apparent.

Both these crayfish have mixtures of visual pigments in their eyes, based on retinal, and yield mixed photopigment extracts. In both animals the chief component is a pigment that absorbs much further toward the red than any vertebrate rhodopsin, and resembles in this respect the vertebrate cone pigment, iodopsin. The *Procambarus* pigment, with  $\lambda_{\max}$  about 556 m $\mu$ , falls somewhat short of the spectral sensitivity maximum at about 570 m $\mu$  found by Kennedy and Bruno; and further still from the sensitivity maximum at about 575 m $\mu$  that characterizes the red receptors in what appear to be the colour vision systems of both crayfish<sup>10</sup>. This eye contains large amounts of highly coloured screening pigments that could well be responsible for displacements of sensitivity of this magnitude<sup>13</sup>. It is perhaps pertinent that the eye of *Orconectes* seems to contain much less screening pigment, and perhaps for this reason its "iodopsin" is the red receptor sensitivity more closely. I think that probably the 556 m $\mu$  pigment in *Procambarus* and the 562 m $\mu$  pigment in *Orconectes* represent the red receptor pigments of these animals. It is interesting, because of their other resemblances to vertebrate iodopsin, that the latter is the pigment of the red sensitive cones in human colour vision<sup>14</sup>.

In both crayfish I have also found blue receptors with peak of sensitivity at about 445 m $\mu$  in *Procambarus*, and 435 m $\mu$  in *Orconectes*. They seem to contribute little to the spectral sensitivities of these animals in the dark adapted state. I found no reliable evidence of photopigments with a peak near these wavelengths in extracts. It may well be that the blue sensitive pigment occurs in relatively small amounts in these eyes.

The functions of the "rhodopsins", at 510 m $\mu$  in *Orconectes* and about 525 m $\mu$  in *Procambarus*, remain problematical. Screening pigments could displace the action spectra of these pigments far enough toward the blue to account for the blue receptor sensitivities, but this would make a clumsy and very uneconomical arrangement that seems intrinsically unlikely. It would violate so what is probably a general principle in the construction of colour vision systems. For such systems to behave

Fig. 3. Difference spectrum of the principal visual pigment in extracts of eyes of the southern swamp crayfish, *Procambarus clarkii*, pH 6.95, 27° C. Exposure to deep red light (Corning filter 2404; wavelengths longer than 625 m $\mu$ ) yielded unstable intermediates which continued to bleach in the dark for about 1 h longer. The difference in absorption between the original extract and this final product is shown. It has  $\lambda_{\max}$  about 556 m $\mu$ , and a minimum at about 392 m $\mu$  owing to the formation of retinal, perhaps still bound to opsin. After red light has no further effect, exposure of the residue to yellow light results in a little further bleaching, maximal at about 525 m $\mu$ , and yielding a little more retinal.

reasonably, their photopigments must maintain reasonably parallel kinetics. They must keep in step with one another in bleaching and regeneration. Otherwise their proportions would vary greatly with the conditions of illumination and adaptation, and it should be impossible to associate specific hues with objects in the environment<sup>15,16</sup>.

From this point of view it seems very unlikely that photopigments that bleach as differently as the crayfish "rhodopsins" and "iodopsins" could co-operate with one another in colour vision. The "rhodopsins" probably have some altogether different function. They may operate at higher or lower levels of brightness than the colour vision systems, in that case presenting a further analogy with the relations between vertebrate rhodopsins and iodopsins. It is interesting also that Bruno and Kennedy found that the caudal photoreceptor in *Procambarus*—a pair of light-sensitive neurones in the sixth abdominal ganglion—had its maximal sensitivity at about 500 m $\mu$ <sup>17</sup>, not far from the  $\lambda_{\max}$  of *Procambarus* "rhodopsin".

# Comparative Nutrition in Pregnancy

by

P. R. PAYNE\*

ERICA F. WHEELER\*

Human Nutrition Research Unit,  
National Institute for Medical Research,  
The Ridgeway,  
Mill Hill

Maternal starvation reduces the viability of the offspring less in man than in other mammals. It is suggested that this is associated with the less exacting demands made on the mother by slower growing primate foetuses.

In prosperous as well as in developing countries, it is generally accepted that poverty is accompanied by a reduction in both average weights at birth and the survival rate of infants<sup>1</sup>. The relative importance of the factors which go to make up a poor socio-economic background are less well established, and there is considerable disagreement as to the role of malnutrition in this context.

## Growth Rates of the Foetus at Birth and the Nutritional Demands of Pregnancy

Experimental animals such as the dog<sup>2</sup> and sheep<sup>3</sup> show marked reductions in the size and viability of offspring when the mother is maintained on an inadequate diet. Birth weight in these animals may be reduced by 20–25 per cent, whereas in man a period of severe starvation has been reported to produce a reduction of only 5–10 per cent<sup>4</sup>. It is important to discover whether this apparent insensitivity to nutritional deprivation is due to the existence of some metabolic protective mechanism in the human mother, or to a reduced requirement associated with a rate of foetal growth much slower in relation to the mother's size than that of other species. Figures quoted by previous workers show the relatively slow rate of growth of the human foetus<sup>5</sup>, and Fig. 1 shows that this phenomenon is common to all the primates, because in general they produce smaller offspring than non-primates having the same gestation time. It would therefore be of interest to discover whether foetal growth rate and maternal weight are connected by any general relationship, and to what extent, if any, man and the other primates are exceptions to such a rule.

We have recently shown<sup>6</sup> that the weight curves during prenatal life of a number of species can be satisfactorily described as consisting of an initial "lag" phase, during which growth is very slow, followed by a period when growth conforms to a "cubic" law. This is a mode of growth to be expected of an organism to which nutrients are supplied at a rate directly proportional to its own surface area. This cubic law is expressed as the equation

$$W = a(t-t')^3 \quad (1)$$

where  $a$  is a constant related to the supply of nutrient to the foetus per unit of surface area, and  $t'$  is the length of the "lag" phase prior to the development of effective placental function. This gives an accurate prediction of foetal weight  $w$  at different gestational ages  $t$  for such diverse species as the chick, man and the cow. Differences in rates of development among the foetuses of these species can be ascribed simply to different values of  $a$  and  $t'$ , while the exponent of  $t-t'$  always assumes a value close to 3.

Such a family of parabolas has the useful property that at any given time  $t$ , and weight  $w$ , the rate of growth is proportional to  $\frac{w}{t-t'}$ . This follows from differentiating

$$\text{equation (1) when } \left(\frac{dw}{dt}\right)_{t=t} = 3a(t-t')^2$$

and combining this with the expression, also derived from (1)

$$a = \frac{w_i}{(t_i - t')^3}$$

Hence

$$\left(\frac{dw}{dt}\right)_{t=t_i} = 3 \frac{w_i}{t_i - t'}$$

In particular, at birth, when  $w = w_B$  and  $t = t_B$ ,

$$\frac{dw}{dt} = 3 \frac{w_B}{t_B - t'}$$

Values obtained for  $t'$  by Payne and Wheeler show that it is a small ( $\sim 20$  per cent) and relatively constant proportion of  $t_B$ , and so we can say that at full term the daily increment in weight is simply proportional to  $\frac{nw_B}{t_B}$

where  $n$  is the number in the litter. Mitchell<sup>7</sup> has suggested that the total products of conception may be regarded as growing in constant ratio to the size of the foetus, and hence we can regard the quantity  $\frac{nw_B}{t_B}$  as a valid index of the total metabolic and nutritional load imposed upon the mother at the end of pregnancy. In Table 1 are summarized a set of values of birth weights and gestation times of a number of mammalian species, taken from the

Fig. 1. Birth weights and gestation ages for primates and non-primate mammals. ●, Primates; ▲, non-primates.

\* Present address: Human Nutrition Department, London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1.

Fig. 2. The relationship between maternal weight,  $W_m$ , and the metabolic and nutritional load of pregnancy, represented by the ratio: weight of products of gestation/gestation time ( $nWB/t$ ). ●, Primates,  $nWB/t = 0.00087 W_m^{0.54}$ . ▲, Other mammals,  $nWB/t = 0.0047 W_m^{0.54}$ .

literature. Fig. 2 illustrates the relation obtained when  $nWB/t$  and maternal weight  $w_m$  are plotted on logarithmic scales. The points fall into two groups, consisting of the primates and the other mammals, and it may be seen that the stress of pregnancy imposed on a primate mother is less than that for a non-primate of similar weight. This is reflected in the values of the constants in the regression equations, which are in the ratio of 5 : 1. In the equations describing both groups, however, the exponent of  $w_m$  is the same (0.54), showing that, irrespective of species, the stress of pregnancy does not increase directly in proportion to the size of the mother, but rather in decreasing proportion as  $w_m$  increases. It might have been expected that the stress would increase in proportion to the "metabolic" body size of the mother—that is, that the exponent would be 0.73. The foetus, however, may be considered to be growing at a rate limited by the passage of nutrients across the effective placental surface. If this surface is related to the two-thirds power of placental weight, which is in turn related to the metabolic body size of the mother ( $W_M^{0.73}$ ), then the growth rate of a foetus would be proportional to  $(W_M^{0.73})^{\frac{1}{3}}$ , that is to  $W_M^{0.49}$  which is in close agreement with the observed value.

#### Growth Rate of the Foetus at Birth in Relation to Milk Composition

The low growth velocity exhibited by primates during foetal life is also characteristic of their subsequent growth. In Fig. 3, the curve representing the growth of non-primates is based on that given by Brody<sup>9</sup>. Similarly, the growth curves of three primates have been re-drawn from Schultz<sup>9</sup>, and it can be seen that these species have a much lower growth velocity during the early stages of growth. For example, at birth the rhesus monkey has a similar weight to a beagle, but subsequently takes 8 years to reach an adult weight which the dog has attained within 2 years.

In view of this, it is of interest to see if the composition of the milks of primate and non-primate species reflects differences in nutritive value compatible with these differences in growth performance. In order to relate growth performance to nutritive value it is necessary, first, to express growth rates as a proportion of metabolic body size, an index of which can be calculated as

$$\frac{W_B}{t_B} / W_B^{0.73}$$

and, second, to express the nutritive value of milk as the ratio of utilizable protein to energy content, which may be

Table 1. BIRTH WEIGHTS, GESTATION TIMES AND WEIGHTS OF ADULT FEMALES OF A NUMBER OF MAMMALIAN SPECIES\*

\* This is a summary of data from about 40 sources, details of which can be supplied on request.

expressed as Net Dietary-protein Calories per cent (NDpCal%)<sup>10</sup>.

Table 2 shows such values calculated for several of the species in Table 1. The mean index of growth rate at birth for the non-primates is 107, whereas that for the two primates is 45. The composition of the milk supply reflects the varying growth requirements of the foetuses. Thus there are species differences in the proportion of energy in the milks which is derived from crude protein (protein-Calories per cent), and the distinction between primates and non-primates becomes more striking when a correction is made for the differences in protein quality of the milks. Thus the NDpCal% of non-primate milks is in the region of 12.0 and that of the two primates is close to 8.0.

This evidence provides an explanation of the apparently lower levels of intake necessary to produce damage to the human foetus. This should be taken into account in the application of the results from experimental animals to the evaluation of protein and calorie requirements of man during pregnancy. The data presented in Fig. 2 show that it is a fundamental feature of the primate order that the metabolic stress of pregnancy is related to a smaller fraction of maternal body weight than in other mammals. Slow growth and a long development period are commonly

Fig. 3. Comparative growth of three primates, with a curve, taken from Brody<sup>9</sup>, representing all non-primate species.

Table 2. INDEX OF GROWTH RATE AT BIRTH AND NUTRITIVE VALUE OF MILK, FOR SEVERAL SPECIES

Species	Index of growth rate at birth	Protein value of milk	
	$\frac{W_{Birth}}{W_{9-12B}} \times 10^4$	Protein-calories per cent	NDpCal%
Rat	110	34	12.5

Rabbit	145	27	12.6
Dog	118	25	—
Pig	95	20	12.6
Cow	94	28	12.0
Orang-utan	42	9.4	7.5
Man	48	10.0	8.0

held to be characteristic only of the higher primates<sup>11</sup>, although very few examples of complete growth curves are available in the literature. The slow growth (see Fig. 1) of the fetuses of all primates suggests, however, that a long maturation period may be a common characteristic of the whole order. This observation, together with the larger

cephalization coefficients demonstrated by Stahl<sup>12</sup>, may be significant in the context of the group learning characteristics of primates.

## Autonomy of H-2 Genes in Individual Immunocytes

by  
FRANCO CELADA  
GEORGE KLEIN

Department of Tumor Biology,  
Karolinska Institute,  
Stockholm

Antibody forming cells express one of two codominant alleles in the case of allotypes and perhaps of other traits connected with the formation of immunoglobulin. That this property does not apply to all genetic systems of these cells is demonstrated by the presence of both parental histocompatibility antigens in heterozygous immunocytes.

SINGLE antibody forming cells do not express all the genetic potentialities of immunoglobulin synthesis, but each one expresses some of the information available in the organism. This results in a cellular mosaic such that each of the different antibody molecules present in the circulation (characterized by their class of heavy chain; type of light chain; allotype and specificity) corresponds to a cell or cell line<sup>1-3</sup>. This phenomenon may have a selective advantage; it makes possible considerable genetic variation, and at the same time avoids the danger of mounting asymmetrical (heterologous) antibody molecules<sup>4</sup>.

The mechanism by which the phenotype of immunocytes is restricted is not known, but it seems to be acting at two different levels. There is (a) a choice of expressing one of a series of genes on the same chromosome, as in the case of three classes of mouse heavy chain, or of four human  $\gamma$ G sub-classes which are coded by closely linked genes<sup>5,6</sup>, and (b) a choice between two alleles codominant at the level of the organism, as in the case of the allotypes in man, rabbit and mouse, where each heterozygous cell expresses the allele of one or the other parent<sup>4</sup>.

While (a) as a selective activation or repression of a portion of the genome is a general if unexplained phenomenon in differentiation, (b) seems to be more peculiar: in mammals a cellular mosaic has only been found in relation to sex linked traits<sup>7,8</sup>. In the case of immunocompetent cells, we can envisage mechanisms which range from the exclusion of single alleles to the inactivation of chromosomal portions or entire chromosomes, similar to the inactivation of one of the X chromosomes of the female somatic cell<sup>9</sup>. Another possibility is that immunocytes contain one or more pairs of autosomes inherited from the same parent as a result of atypical somatic segregation<sup>10</sup>. This reasoning is based on the discovering in deer-mice (*Peromyscus*), heterozygous for a chromosomal marker, of some diploid cells with a reconstituted homozygous karyotype. These cells were found only in the spleen.

Until the chromosomes of identified antibody forming cells are analysed, the possibility of such genomic segregation giving rise to homozygous cells in the immune system cannot be tested. This explanation postulates, however, the involvement of several autosomes, because otherwise the inactivation of non-linked genes (determinants of H and L chain allotypes) in multiple heterozygotes cannot be explained.

One way to investigate the mechanism of allelic exclusion during differentiation of the antibody forming cell is to examine the phenotypic expression of other genetic markers which are unrelated to antibody formation and expressed at the cellular level. We have investigated the antigenic products of the H-2 locus and particularly the autonomy of their expression, in immunocytes of heterozygous origin. Both *in vivo* and *in vitro* experiments were carried out.

We used an *in vivo* transfer system which has been standardized in our laboratory<sup>11</sup>. Donors were *A/Sn*, *A.SW* and (*A/Sn*  $\times$  *A.SW*)  $F_1$  mice, immunized 6-8 weeks before the experiment with 5 mg of human serum albumin (HSA) in Freund's adjuvant which was injected subcutaneously. To sensitize recipients against prospective donors,  $2 \times 10^7$  spleen cells of the prospective donor's genotype were injected intraperitoneally 10 days before the transfer. This has been shown previously to be effective; the sensitized state thus obtained is highly radioresistant<sup>12</sup>. One hour before transfer the recipients were exposed to 450 r. of X-rays. A fixed dose of  $2 \times 10^7$  donor spleen cells was injected intravenously, followed by 10  $\mu$ g of human serum albumin administered intraperitoneally. This dose of antigen is optimal to elicit a secondary response from the transfer cells, while causing no primary response in an intact animal.

The recipients were bled 7, 14 and 21 days after transfer. Their serum was titrated for human serum albumin-binding antibodies by a modified Farr technique<sup>11</sup>. In

these conditions the survival of transferred donor cells was tested by determining their ability to produce a secondary response against human serum albumin. This system is very sensitive<sup>12</sup> and the parental strains used, the coisogenic lines established by Snell on an *A/Sn* background<sup>13</sup>, differ antigenically only in the products of the H-2 locus, and so it was possible to test for the presence of both parental antigens on  $F_1$  immunocompetent "precursor" cells. These cells were transferred into both cross immunized parental lines (*A/Sn* anti *A.SW* and *A.SW* anti *A/Sn*) and as a positive control for optimal growth into syngeneic  $F_1$  recipients (Table 1c). As negative controls, to check the efficiency of immunoselection, immune parental donor cells were also injected into syngeneic recipients and into specifically sensitized opposite parents (Table 1a and b). The results showed that (a) all cells were able to survive and function in syngeneic recipients, (b) the selective system was efficient, and (c) precursor cells of  $F_1$  origin were unable to function in either parental mice, where they produced less than 1/400 of the antibody made in the syngeneic recipient (the difference in log titres was greater than 2.672). Thus precursor cells seem to express their full genotype as far as transplantation antigens are concerned.

Table 1. SUMMARY OF *in vivo* EXPERIMENTS

	Donor cells	Recipients	Log ABC
(a)	<i>A/Sn</i> anti HSA	<i>A/Sn</i>	1.123 ± 0.25
	<i>A/Sn</i> anti HSA	<i>A.SW</i> anti <i>A/Sn</i>	< -1.0
(b)	<i>A.SW</i> anti HSA	<i>A.SW</i>	1.700 ± 0.30
	<i>A.SW</i> anti HSA	<i>A/Sn</i> anti <i>A.SW</i>	< -1.0
(c)	<i>A/Sn</i> × <i>A.SW</i> anti HSA	<i>A/Sn</i> × <i>A.SW</i>	1.672 ± 0.16
	<i>A/Sn</i> × <i>A.SW</i> anti HSA	<i>A.SW</i> anti <i>A/Sn</i>	< -1.0
	<i>A/Sn</i> × <i>A.SW</i> anti HSA	<i>A/Sn</i> anti <i>A.SW</i>	< -1.0

Peak titres of secondary response of  $10^7$  pre-immunized spleen cells, transferred into irradiated syngeneic or to presensitized allogeneic recipients.

The titres are expressed as mean log ABC (antigen binding capacity) of groups of 8-10 mice ± 95 per cent confidence limits.

To test the expression of H-2 antigens on the antibody forming cells themselves the cytotoxicity of selected antisera was tested against homozygous and heterozygous target cells, capable of producing zonal haemolysis of sheep red blood cells in gel. Direct (A) and indirect (B) experiments on *A/Sn* and (*A/Sn* × *A.CA*)  $F_1$  target cells were performed, using the following antisera: *A/Sn* anti *A.CA*; *A.CA* anti *A/Sn*; anti 3 from (*A.CA* × *C57BL*)  $F_1$  mice immunized with *A.SW* cells; anti 4 (contains possibly anti 10 and anti 12) from (*C3H* × *C57BL*)  $F_1$  mice immunized with *DBA/2* cells; anti 5 (contains possibly anti 28 and anti 29) from *A.CA* mice immunized against *S2Y*, a tumour of *ABY* genotype; anti 8 (contains also anti 10 and anti 13) from (*A.SW* × *C57BL*)  $F_1$  mice immunized with *DBA/2* material; anti 9 from (*A* × *A.SW*)  $F_1$  mice immunized with *A.CA* material; anti 11 (contains possibly anti 1 and anti 25) from (*DBA/2* × *C57BL*)  $F_1$  mice immunized with *C3H* cells.

In (A) experiments the test mice were injected intraperitoneally with  $4 \times 10^8$  sheep erythrocytes. Between 3 and 5 days later they were killed and suspended spleen cells were mixed with fluid agarose (final concentration 0.65 per cent in Eagle's medium) in a water bath at 42° C and sheep erythrocytes ( $2 \times 10^5$ /ml.). The average concentration of spleen cells was  $5 \times 10^5$ /ml., 0.8 ml. of the mixture was plated as a thin layer on Falcon tissue culture dishes of diameter 5 cm. The plates were incubated for 30 min at 37° C in a humid atmosphere saturated with carbon dioxide. Two variations of the remaining procedure were then followed. While the results were comparable one method was more economical on antiserum consumption, and the other gave a slightly better survival of the negative control cells.

In the first method, guinea-pig complement was added (dilution 1:15, 1 ml./plate) and the plates were reincubated for 30 min. After this period the haemolytic plaques were visible. A small quantity of antiserum or control serum (estimated as a fraction of a  $\mu$ l.) was layered on the top of each plaque by means of a fine Pasteur pipette. The plates were incubated for 20 min, after which complement was added again in a concentration of 1:5. After 30 min the complement was washed away, the plates were rinsed twice with Eagle's medium and exposed for 15 min to 1 ml. of phosphate buffered saline containing 10  $\mu$ g of fluorescein diacetate. After a final rinse they were ready to be examined at the microscope.

In the second method, the plates were first exposed to the fluorescein diacetate substrate for 15 min. Antiserum 1:2 (~20  $\mu$ l./plate) was then spread on the central part of the agarose surface with a Pasteur pipette. After 20 min of incubation 1 ml. of guinea-pig complement 1:5 was added, and the plates were incubated for 30 min. This had the double effect of developing the haemolytic plaques and of producing a cytotoxic effect on the nucleated cells which had been attacked by the antiserum.

The principle of the fluorochromatic cytotoxic test has been described by Celada and Rotman<sup>14</sup>. The capacity of uptake and retention of the hydrolysed substrate depends on the integrity of the cell membrane<sup>15</sup>. Living cells exhibit intense diffuse intracellular fluorescence. Damage to the cell membrane by, for example, antibody and complement leads to rapid loss of fluorescence by rapid diffusion of the small fluorescein molecule. In the present test, the single plaque forming cells, located in the geometrical centre of the zone of haemolysis, were examined in a darkfield microscope under blue light; if they exhibited fluorescence they were scored as "living", and if they failed to do so they were scored as "dead".

Where the identification of the central cell was uncertain because of clumping or of presence of several cells in the central area, plaques were not scored. These plaques amounted to about 20 per cent of the total examined.

The first column of Table 2 shows the results obtained by the fluorochromasia test. Specific antisera directed against the whole H-2 complex, or against certain H-2 factors only, killed a large percentage of the plaque forming cells in every case, both when *A/Sn* and when *A/Sn* × *A.CA* cells were used as targets. Whenever a direct comparison was done, there was no significant difference between the susceptibility of parental and  $F_1$  cells to the same antiserum. All oligofactorial antisera which were tested on  $F_1$  cells only (anti 3, anti 4, anti 5 and anti 9) gave a very high specific killing (59, 75, 91 and 87 per cent respectively).

The indirect (B) experiment was done as follows. Target spleen cell suspensions (0.3 ml.), derived from mice pre-immunized with sheep red blood cells, were incubated for 15 min in small tubes with 0.02 ml. of antiserum. Complement (1:4, 0.1 ml.) was added to the mixture and the tubes were reincubated for 30 min. They were then centrifuged, the supernatant discarded and the pellet resuspended in 0.1 ml. of Eagle's medium. These suspensions were plated by the usual technique described by Jerne<sup>16</sup>. The number of haemolytic plaques obtained with the suspensions treated with antiserum was expressed as a percentage of the number found with a suspension treated with the corresponding control serum.

The second column of Table 2 shows the results of this test. The cytotoxic effect of the reciprocal anti *A/Sn* and anti *A.CA* antisera as well as of the oligospecific sera was at least as high against heterozygous as against homozygous *A/Sn* cells.

Comparison of the first and second columns of Table 2, that is, of the direct and indirect cytotoxicity test on antibody forming cells, shows that the results are superimposable both quantitatively and qualitatively, and therefore

The "% specific killing" was calculated by considering the fraction of dead PFC found in the negative controls (averaging 16 per cent) as non-specific, and correcting the % killing in the experimental assays accordingly.

corroborate each other. Comparison of these combined data with the titres obtained by testing with the same antisera against lymph node suspensions in the ordinary cytotoxic test (third column, Table 2) shows also a general agreement. This means that cells actually producing antibodies are as sensitive to cytotoxicity as the lymphoid cell population as a whole.

The present experiments have shown that the adoptive transfer of an immune response by  $F_1$  hybrid cells to each of the coisogenic parental lines is totally inhibited by the homograft reaction. Plaque forming cells of  $F_1$  hybrid origin were killed *in vitro* by antisera against each parent's H-2 antigens, and at the same rate as the corresponding parental cells.

This means that all  $F_1$  memory cells, that is, the sensitized precursors of the antibody forming population, express H-2 factors of both parental strains and can therefore be recognized as foreign by either one, and that this is also true for cells engaged in antibody production. This second conclusion was not implicit in the first one, because there is no definite evidence that memory cells and antibody forming cells are identical, although antibody producers seem to derive from memory cells through mitosis and differentiation.

The fact that a cell of  $A/Sn \times A.CA$   $F_1$  genotype is killed both by anti A/Sn and by anti A.CA antibodies does not prove that all factors of the H-2<sup>a</sup> and the H-2<sup>f</sup>

complex are expressed on its surface; the presence of part of them would probably suffice to cause a high susceptibility to antibody and complement. It follows that the expression of antigens may still be restricted to part of the antigens of both parental types. This reasoning is more difficult to defend, however, in the case where the PFC-inhibition test was carried out at a low serum concentration (see Table 2, column 2a): the homozygous cells should be differentially favoured in these conditions, but this was not the case. It is even more improbable when the results obtained with oligospecific antisera are considered.

We tentatively conclude that both parental genes are active in the  $F_1$  immunocytes also at the single factor level, with the reservation that the "monospecific" sera might contain antibodies directed against some other weak H-2 factor (for example, 10, 13, 25, 28, 29) in addition to the one which appears on their label.

These conclusions have an indirect bearing on the mechanism of the phenotypic restriction operating at the level of immunoglobulin synthesis in single cells. They exclude some of the proposed or possible mechanisms for this phenomenon, for example, that the antibody forming cell is, or behaves like, a completely hemizygous cell, or that it carries several chromosomes inactivated at random. They are instead compatible with the hypothesis that allelic exclusion or, conversely, selective activa-

tion affects loci concerned with antibody synthesis in a specific way, while the other genes of the same cell enjoy normal expression.

This work was supported by the Swedish Cancer Society, the Swedish Medical Council, the US National Institutes of Health, the Sir Samuel Scott of Yews Trust and the Magn. Bergwall Foundation. We thank Mr Karol Swiech, who carried out the standard cytotoxicity tests.

## Steroid Hormones in Sick-cell Disease

by

W. A. ISAACS

F. G. J. HAYHOE

Department of Medicine,  
University of Cambridge

Progesterone, testosterone and nor-androstenolone can inhibit the development of sickling in sickle cell disease, which they seem to do by stabilizing the membrane of the erythrocyte. This could be medically useful.

THE clinical features of sickle cell anaemia fall into two classes, those arising from the short survival of the erythrocyte, comparable in many respects with the features of other haemolytic anaemias, and those caused by local obstruction of the micro-circulation from impacted deformed sickle cells, with consequent formation of infarcts. The sickling infarcts may occur at various sites, notably the spleen, parts of the skeleton, the lungs and the central nervous system, and produce painful and disabling effects.

When the structural defect of the haemoglobin molecule in sickle cell anaemia was recognized, after the demonstration by Pauling and his colleagues<sup>1</sup> of a difference in electrophoretic mobility of the abnormal haemoglobin S as compared with normal haemoglobin A, and the later definition of the molecular abnormality in haemoglobin S as replacement of a glutamic acid residue in the sixth position in the  $\beta$ -chain by a valine residue<sup>2,3</sup>, there was great interest in determining how this change actually resulted in disease, and hope that means might be found to counteract the process and achieve an effective treatment.

There seems little doubt that the sickling deformation of the erythrocytes results from intracorporeal formation of long, unidirectional haemoglobin crystals or tactoids, which can be observed microscopically in affected cells before sickling. Perutz and Mitchison showed that deoxygenated haemoglobin S is more insoluble than deoxygenated solutions of haemoglobin A (ref. 4), and Harris demonstrated tactoid formation in deoxygenated solutions of haemoglobin S (ref. 5). Certain hydrocarbons (such as methane, ethane and propane) reverse the process of gel formation and from a consideration of the mechanism of this effect Murayama<sup>6</sup> proposed that hydrophobic bonding between the N-terminal valine and the valine in the sixth position of haemoglobin S was responsible for the sickling process. Satisfactory models for the sickling phenomenon could be constructed on this basis. Efforts to reverse the sickling process *in vitro* and *in vivo* include those of Lewis<sup>7,8</sup>, who made several attempts to inhibit sickling with promazine alone or in combination with dapsone, and reported a prolongation of red cell survival in patients suffering from sickle cell anaemia and given promazine.

Neither of these agents has been shown to inhibit sickling consistently *in vitro*, and there has never been a demonstration of inhibition of sickling after *in vivo* administration of any agent. Kosower *et al.*<sup>9</sup> have recently used the N-carboxy-anhydride of glutamic acid at pH 10 to increase the solubility of deoxyhaemoglobin S *in vitro* and are working to find suitable conditions for bringing about similar "protein transformations" *in vivo*.

During an investigation of possible differences in the mitotic cycle of bone marrow cells treated with testosterone as compared with those of untreated marrow an effect of testosterone on the sickling process was found. Two prescription bottles with 6 ml. each of a growth medium consisting of 20 per cent T.C. 199, 15 per cent horse serum, 15 per cent pooled AB serum and 50 per cent Hanks solution were inoculated with bone marrow aspirated from a sickle cell haemoglobin carrier. One bottle had 1  $\mu$ g/ml. of testosterone propionate added to it and both contained 0.5  $\mu$ c./ml. of tritiated thymidine. The first set of Romanowsky stained smears made from the untreated bottle at 3 h showed that a large proportion of the erythrocytes were needle-shaped (Fig. 1), whereas those from the bottle treated with

Fig. 1. Smear of 3 h marrow culture, incubated without testosterone, from a subject with Hb AS; lanceolate erythrocytes are conspicuous.

Fig. 2. Preparation similar to that in Fig. 1, except that testosterone was added to the culture medium; the erythrocytes remain normocytic.

Fig. 3. Smear made from peripheral blood of a subject with Hb AS after 36 h incubation without testosterone. Many erythrocytes are deformed.

Fig. 4. Preparation similar to that in Fig. 3, except that testosterone was added to the incubate; the erythrocytes remain normocytic.

testosterone retained a round shape (Fig. 2). The only difference between the two bottles was the presence of testosterone in one and not in the other, and so it seemed possible that the oxygen content of the environment was lowered in the bottles, causing a sickling tendency, which was somehow counteracted by the presence of testosterone in the treated bottle. Similar samples were obtained from each bottle, spun down and the cells subjected to the sickling test<sup>10</sup> (in which the oxygen in the environment is removed with 2 per cent sodium metabisulphite). While there was 100 per cent sickling within a few minutes in the untreated preparation, less than 5 per cent of the treated preparation of cells sickled after 1 h. Smears were made from the two culture bottles at intervals and the difference observed here persisted for 51 h. The culture experiments

were repeated using blood instead of the marrow. The same effect of added testosterone was observed, although it took 36 h for sickling to appear in the control culture. This was presumably because peripheral blood cells metabolize less actively than marrow cells and require more time to develop acidotic conditions (needed for sickling to take place) in the culture (Figs. 3 and 4).

Sickle cell suspensions in 2 per cent sodium metabisulphite (using haemoglobin S fingerprick blood) were then made in wells formed by sealing coverslips to both sides of a drilled microscope slide. After complete sickling had been observed, 1  $\mu$ g/ml. of testosterone, primolut (17-OH progesterone), durabolin (nor-androstenedione phenyl propionate), prednisolone, oestrone and T.C. 199 respectively were added to different preparations. Identical operations were carried out on a sample of haemoglobin A blood. Reversal of sickling was obtained in the preparations treated with progesterone, testosterone and nor-androstenedione, and was maximal (virtually 100 per cent) at 24 h. The cells remained sickled in the preparations containing prednisolone, oestrone and T.C. 199. The haemoglobin A preparations showed no obvious changes during the whole procedure (Figs. 5, 6, 7 and 8).

An experiment was then carried out to determine whether the *in vitro* effects of testosterone and progesterone were paralleled by *in vivo* effects. Ten milligrams of testosterone propionate in oil was injected intramuscularly into a male sickle cell carrier; 24 h afterwards the sodium metabisulphite test resulted in prompt sickling in erythrocytes obtained from the subject, but 4 h later the same procedure produced less than 5 per cent sickling in several preparations. This effect persisted for 2 days, after which the sodium metabisulphite test again became promptly positive. Two weeks later, the whole experiment was repeated in the same subject, when complete inhibition

Fig. 5. Phase contrast photograph showing sickling produced by sodium metabisulphite; erythrocytes from a subject with Hb AS. Addition of T.C. 199 produced no change.

Fig. 6. A similar preparation to that in Fig. 5, but showing reversal of sickling after the addition of progesterone.

was first observed 48 h after the injection. This seems to indicate some variation in the rates of absorption of this oily steroid preparation from an intramuscular site of injection.

The investigations of the sickling phenomenon after administration of testosterone and progesterone were next repeated using patients with sickle cell disease. Primolut (17-hydroxy progesterone) in a dose of 12 mg was injected intramuscularly into a 41 yr old female with sickle cell haemoglobin C disease and sodium metabisulphite tests were carried out at intervals on fingerprick blood. Two 4 yr old males with sickle cell disease were investigated similarly, using 5 mg of testosterone propionate in place of the progesterone preparation. The results are shown in Table 1.

Table 1

Patients		Percentage inhibition of sickling			
		2 days	3 days	4 days	7 days
1 Female, aged 41	Hb SC	50-70	—	95	—
2 Male, aged 4	Hb SS	70	95	—	—
3 Male, aged 4	Hb SS	70	95	—	80

Osmotic fragility tests (using buffered saline solutions)<sup>11</sup> were carried out on blood from patient 3 in Table 1, his mother (Hb AS), a male carrier (Hb AS) and his daughter (Hb AS), two normal controls and a patient with congenital spherocytosis. The results are shown in Fig. 9. It would appear that the parenteral administration of testosterone did not affect the osmotic fragility of the red cells.

Radioactive chromium (chromium-51) studies were also carried out on patient 3 before and during parenteral administration of testosterone. The method used was that described by Dacie and Lewis<sup>11</sup>, the cells being washed twice with 1.2 normal saline. Administration of 5 mg of testosterone before and 5 mg during the study of red cell

Fig. 7. A similar preparation to that in Fig. 5, but showing reversal of sickling after the addition of testosterone.

Fig. 8. A control preparation, treated similarly to that shown in Fig. 7, but using erythrocytes from a normal subject (Hb AA).

Fig. 9. Erythrocyte osmotic fragility curves from subjects with Hb SS, Hb AS or Hb AA, as described in the text.

Fig. 10. Chromium-51 erythrocyte survival curves of Hb SS subject before and after treatment with testosterone. ●, Before treatment with testosterone (5 mg testosterone given after the chromium-51 count at 3 days); ○, after treatment with testosterone (5 mg testosterone given 3 days before start of counts and 5 mg given after chromium-51 counts at 2 days). Mean cell life: 13.1 days (before), 10.4 days (after). Chromium-51  $T_{1/2}$ : 8.5 days (before), 6.8 days (after).

Fig. 11. External scintillation counts of chromium-51 during erythrocyte survival studies on a subject with Hb SS before and after treatment with testosterone. Before testosterone: ●, heart; ▲, spleen; ■, liver. After testosterone: ○, heart; △, spleen; □, liver.

survival decreased survival slightly (Fig. 10). External scintillation counting showed that administration of testosterone was followed by some degree of erythrocyte sequestration in the spleen in addition to the sequestration observed in the liver before administration of testosterone (Fig. 11).

It seems clear that there is an effect of testosterone and similar steroids on the sickling process *in vitro* and *in vivo*, although this effect did not enhance erythrocyte survival in the single case so far investigated in this respect. The mechanism of the action of testosterone remains to be elucidated. The sequence of events observed in the experiments demonstrating reversal of sickling shows similarities to the changes noticed when small defects were caused in the membrane of the sickle cell erythrocyte after micro-incision by a laser beam<sup>12</sup>. In addition, the time required for the testosterone to produce the effect in the first experiment with the bone marrow is probably too short for any important intracellular change to have taken place. This would suggest that the effect of this

group of steroids might be on the membrane, and the work of De Venuto<sup>13</sup> suggests that *in vitro* progesterone probably only gets adsorbed on the membrane. Furthermore, crystal like appearances were observed in the wet preparations of sickled cells treated with testosterone and progesterone under phase-contrast (Figs. 6 and 7), which suggests that the crystals of haemoglobin S are still being formed, but they fail to deform the membrane. Subject to the results of future investigation, it seems likely therefore that the effect of these steroids is to stabilize the erythrocyte membrane.

Blood transfusions and administration of alkali and supportive measures currently form the standard treatment for sickle cell disease, and have indeed greatly contributed to decrease in morbidity. None of the alternative procedures proposed, including chronic carbon monoxide poisoning<sup>14</sup>, oxidation to methaemoglobin S (ref. 15), or combined promazine and dapsone therapy<sup>7,8</sup>, has been shown to alter the general course of the disease. While the experiments reported here do not suggest that treatment with testosterone or progesterone would affect the haemolytic component, there is a possibility worth clinical exploration, that sickling crises might be halted by prompt administration of the appropriate steroid or perhaps prevented by low-dosage maintenance therapy.

We thank Professor H. Lehmann for his advice, Dr D. Gairdner for permission to study two children in his care, Dr D. Chalmers for lending equipment, Mr Szaz and Mr R. Flemans for technical assistance and the staff of the Department of Medicine who gave blood for various tests. One of us (W. A. I.) is recipient of a grant from the World Health Organization.

## Metabolism of Labelled Carcinogenic Hydrocarbons in Rats

by

P. M. DANIEL  
O. E. PRATT

Department of Neuropathology,  
Maudsley Hospital and Institute of Psychiatry,  
De Crespigny Park, Denmark Hill, London

MARJORIE M. L. PRICHARD

Nuffield Institute for Medical Research,  
University of Oxford

Polynuclear hydrocarbons given by stomach tube induce mammary tumours. Their absorption, distribution and excretion have been studied. Prolonged retention in ovaries and adrenals may reflect the fact that both these organs produce steroid hormones which stimulate mammary growth.

WE have been studying the influence of the pituitary gland on growth<sup>1-4</sup> and on various organs and tissues of the body<sup>5,6</sup>. Tissues studied have included hormone-dependent mammary tumours induced in rats by the intragastric administration of 3-methylcholanthrene and

7,12-dimethylbenz[a]anthracene<sup>7-10</sup>, methods of experimental tumour production pioneered by Huggins<sup>11-13</sup>. Little is known about the fate of these compounds when given by this route, and so we decided to study the absorption, distribution and excretion of four radioactively

labelled polynuclear hydrocarbons, of which three are potent carcinogens and the fourth non-carcinogenic.

Sixty-one young virgin female Sprague-Dawley rats and nine older lactating animals were used. They were maintained on Diet 41B (MRC or Oxoid) and given water freely. The polynuclear hydrocarbons used were: 3-methylcholanthrene (3-MC), 7,12-dimethylbenz[*a*]anthracene (DMBA) and dibenz[*a,h*]anthracene (DahA), which are all carcinogenic, and dibenz[*a,c*]anthracene (DacA) which is closely related but non-carcinogenic. All were labelled either with 14-carbon (specific activity 1–10 mc./mmole) or with a general tritium label (specific activity 0.1–5.0 c./mmole). In each animal a single dose from 5 µg to 2 mg of one of the polynuclear hydrocarbons, dissolved in 0.5 ml. of sesame oil (R. C. Treatt, London), was administered by stomach tube, after food had been withheld for 18 h. This dose is too small to induce mammary tumours, and because we wished also to learn whether the carcinogen is concentrated in tumour tissue, nine of the rats were given 10 mg of 3-MC labelled with tritium three times a week for 7 weeks. This routine reliably induces mammary tumours<sup>14–16</sup>.

Five series of experiments were undertaken: in the first and second experiments, the rats were left intact so that there was no interference with the natural processes of absorption, distribution and excretion of the hydrocarbon, and in the third, fourth and fifth experiments, indwelling catheters were inserted for the collection of various body fluids.

In the first series of experiments, thirty-four rats were kept for periods varying from a few hours to several months after the administration of the hydrocarbon. These animals included the lactating rats and the rats which had been given a tumour-inducing dose of carcinogen. All the rats were finally anaesthetized with ether, the lactating rats were milked and all animals were heparinized and killed by bleeding out. The blood was immediately centrifuged and the separated plasma was frozen. At autopsy, samples were taken in duplicate from most of the tissues of the body, one sample being quickly frozen for assay of the radioactivity and the other fixed in buffered formal-calcium for embedding in paraffin wax and sectioning for autoradiography.

In the second series of experiments, five rats were kept in metabolism cages and urine and faeces were collected for 4 days after administration of the hydrocarbon. At autopsy, blood and tissues were taken as in the first series.

In the third series of experiments, twenty rats were anaesthetized with ether and one end of a polythene catheter, filled with heparinized saline and plugged, was passed into the inferior vena cava by way of the femoral vein, the other end being brought out through the skin of the back. While the rat was still anaesthetized the hydrocarbon was given by stomach tube. The animal was then placed in a restraining cage<sup>17</sup> that allowed normal eating and drinking but did not permit the eating of faeces. After recovery from the anaesthetic, blood samples were taken at regular intervals. The experiments lasted for 1 to 4 days. The procedures at autopsy were as described for the first series of experiments.

In the fourth series of experiments, six rats were used. The procedures were similar to those in the third series, except that in addition to the venous catheter a polythene catheter was inserted into the cisterna chyli (Fig. 1) and exteriorized for the collection of lymph from the gastro-intestinal tract<sup>18</sup> and an indwelling urethral catheter was also inserted. Lymph and urine samples were collected serially in small polythene vials, which were changed at regular intervals when blood samples were also taken. The faeces were collected. Autopsies were carried out as described above.

In the fifth series of experiments, five rats were used. The procedures were similar to those in the fourth series except that, instead of lymph, bile was collected from a catheter placed in the common bile duct. (To maintain a

normal rate of bile secretion in a rat with a bile fistula, 50 mg of sodium glycodeoxycholate was given in aqueous solution at the same time as the hydrocarbon.)

Radioactive assays were carried out with a liquid scintillation counter. Tissues or fluids containing protein were extracted with chloroform-methanol (1:1) and faeces with hot ethanol. Fluids free of protein were assayed directly. Additional samples or extracts were subjected to thin-layer chromatography on silica gel in benzene, and the chromatograms were scanned by means of an 'Actigraph Model III' radiochromatogram scanner (Nuclear Chicago) and by liquid scintillation counting of the material eluted from separate segments.

Fig. 1. Diagram to show site (arrow) where catheter was inserted into cisterna chyli for the collection of gastro-intestinal lymph.

The results of the experiments are considered in three stages. During the first stage, lasting as long as 24 h, much radioactive material was found in the intestinal contents. The amount of radioactive material in the blood plasma rose steadily after administration of the dose of the hydrocarbon, the time of the peak level varying in different animals from 4 to 24 h (Fig. 2). Radioactivity appeared in the gastro-intestinal lymph within about 1 h of administration of the dose (Fig. 3) and throughout the first 24 h the concentration of radioactivity in the lymph continued to be considerably greater than that in the blood plasma (Fig. 4). The lymph was visibly milky during the time when it showed a high concentration of radioactivity. Most of the radioactivity was present in the fat droplets of the lymph, and chromatography suggested that the material was largely unchanged hydrocarbon. The total amount of lymph collected during the first 24 h usually contained radioactive material amounting to about 5 per cent of the dose administered. The bile (Fig. 5) and the urine first showed the presence of radioactive material about 1 h after administration, the concentration in both rising for some hours; the amount in the urine was always less than that in the bile. When the concentration of radioactive material in the blood plasma was near its peak value a similar concentration was present in most of the tissues examined. Tissues, however, such as the liver, kidney, body fat and brown fat, contained rather more radioactive material, while other

Fig. 2. Radioactivity in successive samples of blood plasma of two rats during the first 3 days after intragastric administration of two different polynuclear hydrocarbons, labelled with carbon-14. ●, DMBA; ○, DahA.

tissues, particularly the brain, muscle and salivary gland, contained rather less than the blood (Fig. 6a). At this time the total radioactive material contained in the tissues of the body was approximately 10 per cent of the dose that had been given.

The second stage in the metabolism of the polynuclear hydrocarbons lasted a further 2 or 3 days. The level of radioactivity in the blood plasma decreased rapidly to about 1 per cent of the peak value (Fig. 2). The levels in the lymph and urine also decreased sharply. The amount of radioactivity in the bile, however, tended to continue at a high level for somewhat longer (Fig. 5). Chromatography showed that much of the material extracted from

Fig. 3. Radioactivity/h in serial samples of gastro-intestinal lymph, collected from two rats during the first 24 h after they had been given 8-4 µc. of DahA labelled with carbon-14 in oil by stomach tube.

the plasma, urine and bile was no longer in the form of unchanged hydrocarbons. The faeces contained a considerable quantity of radioactive material. The amount of radioactivity in the tissues decreased during this period, but the various tissues did not all lose radioactivity at the same rate. In the liver and kidneys the loss was relatively rapid, whereas in the adrenals, ovaries and the group of mesenteric lymph nodes through which the greater part of the intestinal lymph passes (Fig. 1) it was relatively slow. Thus at the end of this period, that is, at about 3-4 days, the pattern of distribution of radioactive material in the various tissues had altered considerably (Fig. 6c). The highest concentrations were now present in the adrenals, the body fat, the mesenteric lymph nodes and, in some animals, the ovaries. The brain and muscle still contained the least radioactivity. The milk

Fig. 4. Concentration of radioactive material in serial samples of lymph (—) and of blood plasma (---) collected from a rat given DahA (dose as in Fig. 3).

of the lactating rats was examined 3-7 days after administration of the labelled hydrocarbon and radioactive material was found to be present, chiefly in the butter fat.

The third stage in the metabolic process was studied for several months more. From about 2 weeks after administration of the dose only very small amounts of radioactivity could be detected in the blood plasma (the only body fluid examined during this prolonged period). The concentration of radioactivity in the tissues showed a steady decline, but even at the longest survival times the adrenals, the mesenteric lymph nodes and, in some animals, the body fat and the ovaries still retained higher concentrations of radioactivity than the other tissues. The concentration of radioactive material remaining in the body fat after weeks or months was variable; sometimes it was of the same order as that in the adrenals (Fig. 6e, f) and sometimes it was much less. Normal mammary glands, freed from fat (Fig. 6c), and mammary tumours (Fig. 6f) examined up to 3 months after administration of the radioactive

hydrocarbon, did not show a concentration of radioactivity such as that in the adrenals and body fat, the level being no higher than that found in the other tissues.

During the first two stages of absorption there were some differences in the distribution of radioactive material in the tissues of animals from which the gastro-intestinal lymph or the bile had been collected and in the tissues of those animals from which these fluids were not taken. In the animals from which the lymph had been taken the tissues contained relatively low concentrations except for the liver (Fig. 6b). In animals from which the bile had been collected the tissues usually contained considerably more than the usual amount of radioactive material. The reason for this larger amount may be that the exogenous bile salt given with the dose of polynuclear hydrocarbon in an attempt to compensate for the loss of endogenous bile salts through the bile catheter had facilitated the absorption of the polynuclear hydrocarbon from the gut.

Fig. 5. Radioactivity/h in serial samples of bile collected from a rat during the first 64 h after administration of DahA (dose as in Fig. 3).

The general picture of absorption and excretion was similar for all four polynuclear hydrocarbons, with only minor differences, for example, DMBA seemed to be less rapidly absorbed than were the other three compounds. The findings were substantially the same whether  $^{14}\text{C}$ - or  $^3\text{H}$ -labelled polynuclear hydrocarbons were used, except that some 20–30 per cent of the isotopic label separated from the material labelled with tritium within a few hours after the dose had been given. The separated tritium was detected in the form of water in the urine, in which it was excreted relatively slowly. It was also excreted in the breath, as subsequent experiments have shown.

This study shows that induction of mammary tumours by intragastric administration of carcinogenic hydrocarbons is extremely wasteful of carcinogen, because most of the dose is rapidly excreted from the body in the faeces and urine, and also shows what happens to the small residue which is retained in the body. The first stage in the absorption of hydrocarbon from the gastro-intestinal tract is its entry into the lymphatics of the gut, and presumably, because the carcinogen is dissolved in oil, its transport through the intestinal epithelium is similar to

that of other fatty substances that are absorbed from the intestine. From the lymph the carcinogen, in solution in chylomicrons, is carried into the blood stream which then distributes it to all the tissues of the body. The extent to which the different tissues take up the carcinogen and the periods for which they retain it are variable. At an early stage after administration relatively large quantities of the carcinogen are held for a short period by both the kidney and the liver. From the kidney some of the carcinogen is excreted in the urine, and from the liver it is excreted in the bile. Polycyclic hydrocarbons given intravenously are excreted rapidly in the bile as conjugates of their phenolic derivatives, which undergo hydrolysis

Fig. 6. Concentration of radioactivity in tissues and blood plasma taken at autopsy from six rats at various times after intragastric administration of labelled carcinogenic polynuclear hydrocarbons. The tissues listed here were those taken routinely from all animals in this study. (BP, Brown fat; MLN, mesenteric lymph nodes; SAL GL, salivary gland.) The values for the different animals should not be compared because the radioactivity of the carcinogen given was not the same in each rat. (a) Nine hours after  $^{14}\text{C}$ -DMBA. (b) Twenty-four hours after  $^{14}\text{C}$ -DahA (the gastro-intestinal lymph had been collected from this rat). (c) Twenty-four hours after  $^{14}\text{C}$ -DMBA. (d) Seven days after  $^{14}\text{C}$ -DMBA (lactating rat). (e) Twenty-two days after  $^3\text{H}$ -3-MC. (f) Eighty days after last of multiple doses of  $^3\text{H}$ -3-MC (tumour-inducing dosage).

in the gut, and appear in the faeces as free phenols<sup>19-21</sup>. Our work suggests that after absorption of polycyclic hydrocarbons from the gut they are rapidly excreted in the bile, while probably only very little of the metabolites thus excreted is reabsorbed.

The body fat also takes up much of the absorbed carcinogen at an early stage, but this tissue, unlike the liver and kidney, often retains it for a long period (Fig. 6). The adrenals, and usually also the ovaries, take up the carcinogen in relatively large quantities and elimination from these organs is slow. The variable uptake by the ovaries was probably caused by the carcinogen having been given to the rats at different phases in their oestrous cycles. It is interesting that the brain, although it has such a large content of lipid, is one of the tissues which takes up very little of the carcinogen (Fig. 6). A large proportion of the lipids of the brain, however, consists of polar lipids (for example phospholipids) and it may well be that it is these polar lipids and/or the blood-brain barrier which prevent any substantial uptake of the carcinogen by the neural tissue.

The retention of polynuclear hydrocarbons in the body fat probably has a special significance in relation to the production of mammary tumours by carcinogenic hydrocarbons. The mammary glands (and indeed the mammary tumours) did not show any appreciable concentration of radioactive material, but these glands are embedded in fatty tissue and all body fat takes up a high concentration of the carcinogen and often retains it for a long period. This store of carcinogen in the fat adjacent to the mammary tissue may thus act continuously on the mammary glands in the manner of a locally applied carcinogen. The prolonged retention of carcinogenic hydrocarbons by the adrenals and to a variable extent by the ovaries may also be significant in the induction of mammary tumours. Both these organs produce steroid hormones which promote

mammary growth and steroid hormones are known to have a strong chemical resemblance to carcinogenic hydrocarbons such as DMBA. The retention of carcinogenic hydrocarbons in the adrenals and the ovaries suggests a physiological as well as a chemical parallel between these substances. If this were so it could explain why these carcinogenic hydrocarbons act selectively on tissue which is a target organ for the steroid hormones of the adrenals and the ovaries.

This work was supported by grants from the Royal Society, the Nuffield Foundation and the British Empire Cancer Campaign for Research.

Prince Edward Island

Radiocarbon dating suggests that warm water oysters and bay scallops migrated northwards during and after the climatic thermal maximum. The bay scallops may have arrived too late to reach areas in Canada which are now favourable for them.

SABLE ISLAND is a low, sandy shoal, about 21 miles long and less than 1 mile wide, and is located 100 miles south-east of Canso, Nova Scotia, near the edge of the Continental Shelf (Fig. 1). The presence on the beaches of "drift shells" which do not occur alive near Sable Island has long been known<sup>1</sup>. Investigations of the significance of these shells with respect to the postglacial marine zoo-

geography of eastern Canada and the post-Pleistocene history of Sable Island have just begun<sup>2</sup>.

Neither oysters (*Crassostrea virginica* (Gmelin)) nor bay scallops (*Aequipecten irradians sablensis* Clarke) now live near the island, but shells of these and of some other species which may also be locally extinct are often found on the beaches and the surrounding Sable Island Bank<sup>3</sup>.

The ages of oyster and bay scallop shells washed on to the beaches and of a sample of peat dredged from 1 mile south-east of Sable Island from a depth of 10 m have been determined by the radiocarbon method. The ages are shown in Table 1.

Additional oyster shells collected on North Beach near West Light and on South Beach near Wallace Lake were examined for characters indicative of ecology and for growth characteristics. Most specimens were found to have numerous deep and wide chalky deposits between

One of the North Beach shells is infected by blister worm (*Polydora*) and another, together with a specimen from South Beach, seems to have been attacked by boring sponge (*Cliona*). The *Polydora* infestations, at least, almost certainly occurred while the oysters were living. Although *Polydora* often infests in salinities low enough to produce the chalky deposits noted here, *Cliona* is only associated with higher salinities. All these observations suggest that the individuals involved come from widely varying and widely separate environments. Finally, the shell ridges

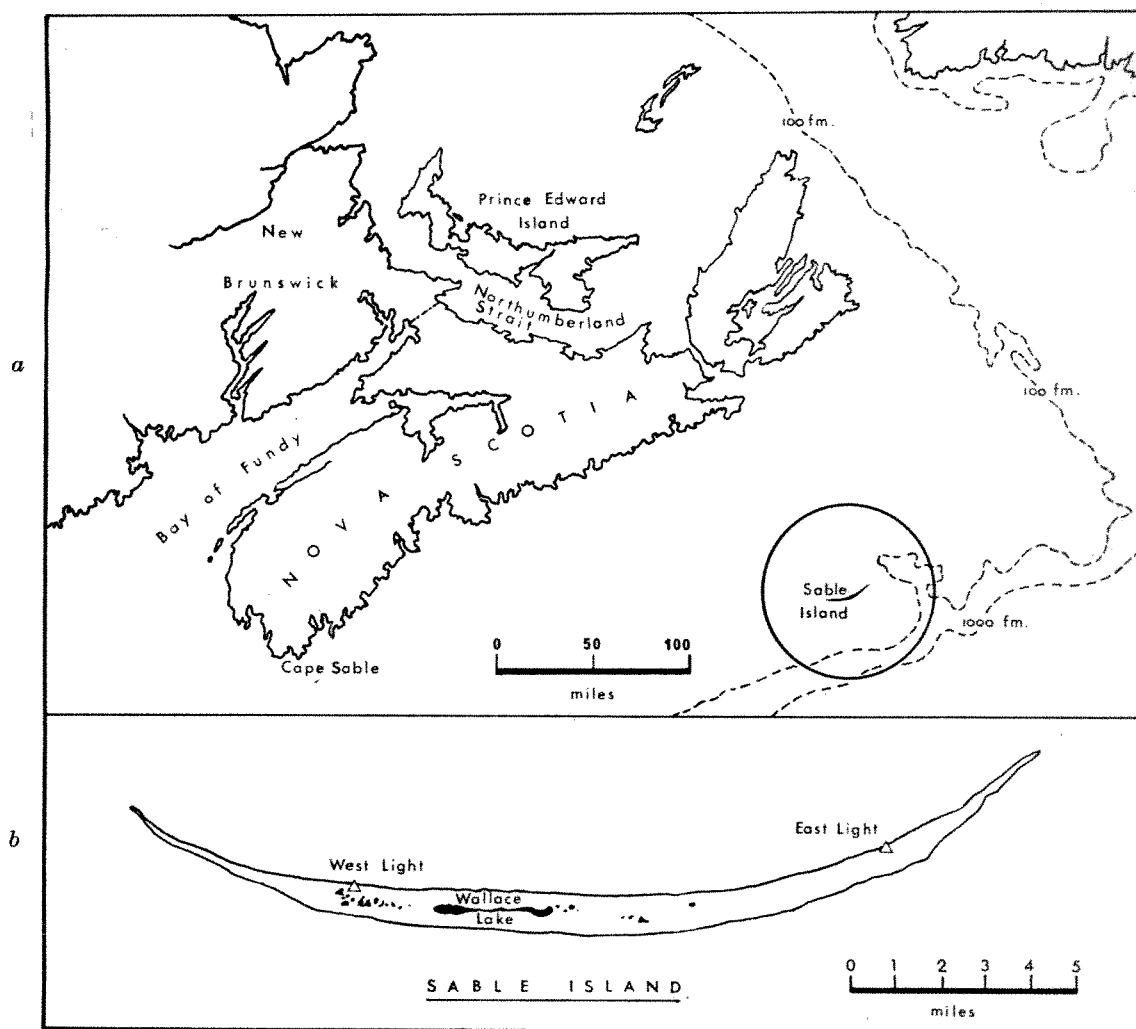

Fig. 1. (a) Location of Sable Island and of other areas mentioned in the text. (b) Map of Sable Island with ponds and lakes shown in black.

thin layers of calcite-ostracum. This is characteristic of a brackish-water habitat<sup>4,5</sup>. Similar oysters now live in Bras d'Or Lake, Cape Breton Island, Nova Scotia, and at the head of saltwater-freshwater estuaries. The specimens from North Beach also show considerable variation in shell shape. Some have thin shells with large ratios of length : width, twisted lips, and left valves with little "cupping"—characteristics of oysters growing in clumps on soft substratum. Others have thicker shells with small ratios of length : width and deeply cupped left valves—characteristics of oysters growing on firm substratum. Both soft and firm substrata often occur, however, in close proximity in oyster habitats.

imply that the oysters grew quite rapidly—as fast as, or perhaps a little faster than, oysters now living in Malpeque Bay, Prince Edward Island. Accurate estimations of shell growth and life span from shell ridges in unknown oyster stocks are not yet possible.

The Sable Island bay scallop shells have been described before<sup>2</sup>. Growth rates, deduced from growth annuli, seem to have been moderate but less than those for the five populations of *Aequipecten irradians irradians* or the eleven populations of *A. i. concentricus*<sup>2</sup>. *A. i. sablensis* represents a distinct sub-species apparently endemic to Sable Island, and so detailed comparisons of that with other bay scallop populations cannot be made with confidence. It is never-

Table 1

No.	Sample No.	Radiocarbon age (years before 1950)	Sable Island location	Remarks
1	Oyster, GSC-635	5,650 ± 140 (inner) 5,320 ± 140 (outer)	North Beach near West Light	Inner and outer layers dated separately—shell not blackened
2	Oyster	4,710 ± 120	Beach flat, S.-S.E. shore of Wallace Lake	
3	Oyster, GSC-634	3,630 ± 130 (black) 3,540 ± 140 (white)	North Beach near West Light	Shell layers alternately blackened and not blackened—layers separated and similar layers combined for dating
4	Bay scallop, GSC-699	1,800 ± 125	North Beach near West Light	Shells not blackened
5	Bay scallop	1,432 ± 125 (ref. 2)	North Beach, unspecified location	Shells not blackened
6	Peat, GAK-748	6,800 ± 150 (ref. 7)	1 mile S.E. of Sable Island, depth 10 m	

theless probable that, like other day scallops, *A. i. sablensis* lived in a bay of medium to high salinity or in a lagoon. Paradoxically *A. i. sablensis* seems to be more closely related to the more southern *A. i. concentricus* (New Jersey to South Carolina, Florida to Texas) than to the more northern *A. i. irradians* (Massachusetts to New Jersey), but even the latter sub-species occurs no closer than 500 miles west-south-west of Sable Island today.

The dates of the oyster shells (about 5,670–3,560 yr B.P.) compare reasonably well with the dates of 6,850 ± 100 yr B.P. and 7,335 ± 105 yr B.P.<sup>6</sup> for ancient oysters collected in Northumberland Strait from 37 and 22 m respectively. The two latter dates are in excellent agreement with the date 6,800 ± 150 yr B.P. determined for the offshore peat<sup>7</sup>. (The plant species which comprise the peat are now being identified by Dr J. Terasmae of the Geological Survey of Canada and their significance will be discussed later.)

On the basis of a sample of salt-marsh peat collected from a depth of 59 m on George's Bank and dated by the radiocarbon method as 11,000 ± 350 yr B.P. Emery *et al.*<sup>8</sup> have deduced that much of George's Bank was subaerially exposed and heavily vegetated about 11,000 yr ago. There has been a steady rise of sea level along the coasts of New England and the Mid-Atlantic States<sup>9,10</sup>. According to the charts presented by Merrill *et al.*<sup>9</sup>, at about 6,800 yr B.P. the ocean level was probably about 10 m lower in those regions than it is at present.

The peat date from the Sable Island sample indicates that about 6,800 yr ago sea level on Sable Island Bank in the vicinity of Sable Island was probably at least 10 m lower than today. This, in turn, implies that the innermost Nova Scotian Shelf and shallow areas near Cape Sable also may have been exposed at that time. The Sable Island peat and oyster dates also correspond well with the climatic thermal maximum (or post-glacial hypsithermal warm period) in eastern Canada<sup>10</sup>. Many warm water marine animals found south of Cape Cod also flourish in the Northumberland Strait region and as small, isolated populations elsewhere in eastern Canada<sup>11</sup>. The dates indicate that oysters, at least, had spread northward to Northumberland Strait by the beginning of the hypsithermal and were at Sable Island about the same time or shortly thereafter.

Bay scallops do not now occur live in eastern Canada. The radiocarbon dates for Sable Island specimens (about 1,820 to 1,450 yr B.P.) correspond to a warming period in eastern Canada when the land temperature was about the same as it is today<sup>9</sup>. This period occurred after a cold period, the onset of which had marked the end of the climatic thermal maximum<sup>9</sup>. The presence of bay scallops at Sable Island at this time agrees well with the concept of an extended and therefore warmer Sable Island where the oceanic influence would temper winter conditions. It also indicates the existence of other suitable habitats between Massachusetts and Sable Island, probably as bays and lagoons along the mainland, before or during that time<sup>10</sup>. Sable Island populations are taxonomically distinct, and this implies that they were isolated for a substantial period there or that the founding stock was itself distinct from other mainland populations and has left no fossils elsewhere. Bay scallops probably migrated north to Sable Island after the hypsithermal warm period and further

migration to the Northumberland Strait region was effectively blocked by cold water or severe winter conditions.

Finally, the dated presence of oysters and scallops at Sable Island reveals much about the island itself. During the period 5,670–3,560 yr B.P. a lagoon or bay must have existed at Sable Island, perhaps in the vicinity of the present large brackish Wallace Lake. Specimens of *Mya arenaria* also attest to the presence of a low energy environment during that time. These have been found in dark brown organic-rich silty sand beneath 3 m of sand on the south shore of Sable Island. These clams lie just above the buried peat horizon. This information combined with the date derived from the peat suggests the existence of a bay with a partially muddy substrate on what is now the southern margin of the island. It suggests that Sable Island was then somewhat wider than it is now. The morphology of many of the Sable Island oysters and their dates, together with the other evidence, imply that a bay or series of bays existed there from about, 6,800 to about 3,600 yr B.P. Within historic time a long, narrow inland lagoon is known to have existed and to have disappeared during the nineteenth century<sup>12</sup>. Today the island is composed only of sand; sand and gravel; and mixtures of sand, gravel and shell. The coasts are high energy environments of continuously moving sand and changing bars<sup>14</sup>.

Whether the oysters disappeared because of disease<sup>14</sup>, climatic worsening, or elevation of sea-level<sup>9</sup> (or other invasion of the habitat by cold oceanic water) is unknown, but the two latter possibilities acting together appear most likely. It seems certain that from 1,450 to 1,820 yr B.P. a bay or lagoon also existed in which bay scallops thrived. It probably was not the same lagoon that supported the oysters earlier but another lagoon, perhaps in the present location of Wallace Lake. Wallace Lake is at present very variable. Its size and salinity fluctuate widely because of periodic freshening during isolation from the sea (a fresh water wedge over salt water underlies the island) and subsequent winter invasion by the sea. Scallops would not have been able to survive freshening of their habitat or gross invasion by cold oceanic water during the summer, but which of these or other reasons are responsible for their extinction is unknown.

# Mineral Deposits on the Moon

by  
GEORGE MUELLER

University of Concepcion,  
Chile  
and  
Institute of Molecular Evolution,  
University of Miami,  
Coral Gables, Florida

Professor Mueller uses evidence from many sources to reconstruct mineral assemblages on the Moon. His findings indicate that the Moon's resources may well be worth exploiting if only the cost of space travel can be reduced.

THIS article is based on the interpretation of recent rocket photography of the Moon and on certain comparisons and extrapolations made on the basis of the properties and theories of genesis of terrestrial deposits which are described in recent textbooks and review articles of economic geology (see, for example, refs. 1-3). Interpretation of rocket photographs from the Moon has led me to the conclusion<sup>4</sup> that it is unlikely that a high proportion of the meteorites known from collections are derived from the Moon. The theory of asteroidal origin seems to be more probable. It appears that the mineral deposit pattern of a given celestial body may depend on its mass, and it is therefore possible that the pattern of mineral deposits for the Moon is in many respects intermediate between that of the Earth and that indicated for the bodies with the size of asteroids (smaller than the Moon) from which the meteorites may be derived.

My principal aim is to assess the extent to which it is possible to reconstruct the mineral assemblage of a given celestial body. This assessment may be tested in the near future in the course of manned lunar landings and explorations. Each genetical class of mineral deposits which might be expected to be found is briefly considered.

**Magmatic segregates.** The gravitational segregation of deposits of refractory minerals from the molten igneous rocks within the Earth's crust is a relatively rare phenomenon. This rarity may explain the lack of any magmatically segregated material among the small number of the meteorites which crystallized from a melt, namely, the achondrites. In view of the low albedo, and therefore the probable basic character of much lunar rock, deposits produced by magmatic segregation—in particular magnetite, pyrite and chromite—are likely to occur, so that the prospects of finding high grade deposits of these minerals would seem to be good. Because of lower rate of erosion, however, dissection of major intrusions cannot occur and the less intensive tectonics and the lower gravitational field of the Moon may be factors adverse to the formation of gravitational segregates. For these reasons outcrops of high pressure, high temperature minerals such as diamonds of the Kimberley type are unlikely to be found. There is an intriguing probability of magmatic segregates within lava flows on the Moon. The existence of this type of deposit has not been conclusively proved on Earth, although I have found indications that haematite-magnetite bodies of El Laco, Northern Chile, were generated in this way. It would seem likely that on the Moon there would be increased chances of encountering such effusive, magmatic, segregates for the following reasons: there is presumably a greater abundance of basic rocks which contain the highest proportion of the refractory minerals and according to the interpretation of lunar photography in general there are a far greater number of individual lava flows preserved on the Moon than on the Earth.

**Fumarole deposits.** The abundance of fumarole and hydrothermal products on the surface of the Moon would primarily depend on the ratio between the number of craters produced by impact and volcanism, because only volcanism would substantially contribute towards the

accumulation of magmatic condensates. On Earth today the ratio volume of impact/volume of volcanic rocks is in the order of  $10^{-8}$  or less. The lower intensity of volcanic activity (due to the smaller mass of the Moon) on the one hand, and the preservation of archaic impact craters on the other hand, may drastically increase the impactite/volcanite ratio on the Moon. I think, however, that it is unlikely that these factors would be responsible for an increase in the ratio of eight orders of magnitude, bringing the ratio in question to unity. It therefore seems likely that the surface of the Moon is rich in fumarole products.

A full discussion of the problem of interpretation of lunar craters<sup>5</sup> is outside the scope of this paper. It should be stressed, however, that most of the terrestrial craters show positive mean elevation, because lava has been added from deep sources in the course of volcanic activity. The rare maar type crater of Nilahue, Southern Chile, has zero mean elevation<sup>6</sup> because all the material was removed as ejecta by gas explosions. The few known or inferred impact craters on Earth also reveal zero mean elevation because under the usual impact velocities the volume of the impacting object is negligible when compared to the volume of rock displaced by the impact. Craters and domes of well defined positive elevation appear on wide angle frame 213 of Orbiter (November 25, 1966), and this fact strongly supports the volcanic origin of at least some of the lunar craters.

On the Earth the fumarole deposits are of more or less transitional character because the sulphur of such deposits becomes oxidized in the atmosphere, and most of the saline condensates are washed away by precipitation into the oceans or into desert basins. Many of the magnesium and potassium ions of these exhalation products of the Earth are later absorbed on the floors of the oceans so that evaporites, which form during the drying out of the marine lagoons, are relatively depleted of these metals, and are therefore enriched in the salts sodium and calcium, which are not so readily absorbed.

On the Moon there is no atmospheric transport and the resulting "fumarole-evaporite" type of deposit must therefore retain its magnesium. Other factors which may contribute to a relatively high percentage of magnesium salts of these lunar deposits would be the alkali poor, basic character of the lunar magma, and the elimination of free sulphur (and possibly also alkalis) through solar radiation and the solar wind, particularly within the older deposits.

The foregoing considerations lead us to the prediction that the surface of the Moon is exceptionally rich in fumarole and evaporite deposits and that the volume of these is comparable (after making allowance for the smaller surface and lower rate of erosion on the Moon) to the total volume of the salts which are concentrated within the terrestrial evaporites, oceans and fumaroles. Such deposits (which may reach masses in the order of several hundred million tons) would have a surface zone affected by solar radiation and the solar wind in which  $MgO$ ,  $MgSO_4$ ,  $MgCO_3$ ,  $MgCl_2$  and some iron and calcium salts would be intermixed with volcanic ejecta, meteorites

and cosmic dust. There is a possibility that with increasing depth in such deposits, the percentage of the relatively more volatile alkali salts, sulphur and hydrocarbons would tend to increase.

It is interesting to note that Kuiper<sup>7</sup> interpreted the white, snow like substance on the peak of the Alphonsus crater (shown on Ranger VII photographs) as a fumarole product which traversed a tuff like material of pyroclastics; he compared this with a white mixture of gypsum and calcium oxide which covered the slopes of Laimanca Volcano, Hawaii, after an eruption. The Orgueil and other type I carbonaceous chondrites show considerable petrological similarities to terrestrial tuffs impregnated with fumarole products<sup>8</sup>. The amount of  $\text{MgSO}_4$ , approximately 15 per cent, which is present in these stones is significant in view of the foregoing considerations and furnishes further indications that magnesium salts may be expected as important constituents of the lunar deposits.

**Hydrothermal deposits.** The lunar pegmatites are expected to be chiefly of basic type, for it is likely that the Moon, because of its low gravitational field, does not have a segregated granitic continental crust. This would favour pegmatites enriched in rare earths, but the economically more important constituents of terrestrial pegmatites, associated with granites—lithium, beryllium, boron and vanadium—may be absent or very subordinate.

As regards the relatively lower temperature, deep-seated hydrothermal deposits, the Moon is expected to be essentially an oceanic type of mineralogical province. This means that the mineral veins may contain volatile condensates characteristic of the terrestrial basic rock, namely copper and iron. Deposits of mercury, bismuth, antimony, gold, lead, zinc, arsenic, barium and phosphorus are associated with all the terrestrial igneous rocks and they may therefore be present in relatively smaller quantities on the Moon. The typical granitic volatiles, that is, molybdenum, tungsten, uranium and fluoride, may, however, be practically absent.

Lack of deep erosion may render the hydrothermal deposits of deep-seated origin relatively rare, and the exposure of types close to the surface more common. These latter contain the sulphides of the heavy metals and some elementary sulphur. Such deposits in question might have little or no thermal zoning, and would have a simple mineralogy of impure ores and gangues, because their cooling and crystallization occurred too rapidly to produce large and well formed crystals of their minor constituents.

Because these deposits will be close to the surface there appear to be good prospects for the presence of arsenic, mercury, antimony and boron. It would seem likely that solar radiation and wind would cause the formation of a surface zone which is depleted in the hydrothermal minerals of extreme volatility, such as yellow sulphur and red  $\text{HgS}$  and  $\text{As}_2\text{S}_3$ . This possible scarcity of coloured minerals may render difficult the visual detection of hydrothermal deposits from coloured photographs, or black-and-white photographs made through different filters. On the photographs made by Rangers VII, VIII and IX, numerous (up to several kilometres long) lodes appear, most of which are of a lighter shade than the surrounding ground. The light colour favours the possibility of fissure fillings of close to the surface fumarole type which have a composition typical of fumarole deposits—rich in earth-alkali and alkali salts with sulphur. The presence of gaping fissures on other photographs may be accounted for either by displacements without the ascent of condensable volatiles (this occurs in the case of non-mineralized faults of the Earth) or the preferential erosion of highly volatile material, possibly sulphur and hydrocarbons which filled the fissures.

I have proposed<sup>8</sup> that the carbonaceous chondrites in general closely resemble terrestrial pyroclastics impregnated with hydrothermal products, and in the type I stones features suggestive of terrestrial fumarole condi-

tions appear as well. According to the computation of data from the up to date literature, the redistribution ratios, that is, p.p.m. in carbonaceous chondrites + p.p.m. in mean chondrites of some of the hitherto determined minor elements are as shown in Table 1.

Table 1

Element	Redistribution ratio
Mercury	220
Bismuth	52
Carbon	19
Lead	17
Silver	16
Zinc	3.9
Copper	2.5
Vanadium	1.9
Sulphur	1.7
Rare earths	1.6
Uranium	1.1

I am at present engaged in statistical work on the terrestrial hydrothermal deposits which indicates that the foregoing redistribution ratios are usually very similar to those between the mean of hydrothermal veins in the terrestrial oceanic provinces and that of the Earth's crust. The only really significant difference is the higher value for sulphur and the lower value for carbon in the terrestrial hydrothermal deposits. Such difference may be explained by the possibility that under the relatively oxidizing conditions within the crust of a comparatively smaller celestial body, sulphur would escape in the free state, and carbon would tend to persist as graphite, amorphous carbon and higher molecular organic substances. Under the relatively more reducing conditions which prevail within the crust of a body the size of the Earth the carbon tends to escape as low molecular hydrocarbons, and a higher proportion of sulphur would be retained as sulphides of iron and other heavy metals. We may therefore expect that the mean sulphur carbon ratio of the lunar hydrothermal deposits would be lower than the value of approximately 10 for the Earth, but higher than that of 1.5 for the carbonaceous meteorites.

**Sedimentary and metamorphic deposits.** No sign of sediment or metamorphosed sediment has been detected among the 2,000 or so meteorites in our hands and it seems unlikely that a relatively small celestial body can retain an atmosphere and hydrosphere for a time sufficient to produce appreciable amounts of sediments. The absence of clear indications of sedimentary rocks on the hitherto published rocket photographs of the Moon suggests that mineral deposits of sedimentary origin may be absent or very subordinate on the Moon. These include secondary concentrations of gold and platinum, minerals of zirconium, thorium, the rare earths and iron and sands, clays, bauxite, limestone, dolomite, chert, phosphorite, garnet and corundum.

**Carbonaceous deposits.** It appears that the Moon may have more carbon in its crust than the Earth has. Reconstruction of how lunar carbon is distributed is difficult because it is not easy to assess the relative importance of several factors.

I have suggested<sup>9</sup> that the mean oxygen/hydrogen ratio will increase and the hydrogen/carbon ratio of a carbonaceous complex will decrease with decreasing mass of a given celestial body. The presence of organisms of terrestrial type would increase the organic carbon and hydrogen/carbon ratio. As the presence of abundant life on the Moon seems unlikely at any stage of its history, it seems probable that the Moon's carbosphere contains more of the Moon's total carbon than Earth but in a more carbonized form (chiefly as graphite and graphitite). The highly aromatic and oxygenated nature of average lunar rock makes it unlikely that craters on the Moon would be filled with tar like hydrocarbons as envisaged by Wilson<sup>10</sup>.

On Earth the concentration of the carbonaceous complex into relatively pure and extensive deposits of coals is principally due to the abundance of living organisms. With the absence or more subordinate character of this

Table 2

Volume and grade compared to similar terrestrial deposits	Magmatic segreg.	Fumarole-evaporite	Hydrothermal	Sedimentary	Carbonaceous	Impactite
Superior	Chromium	MgSO <sub>4</sub>	Arsenic, antimony, selenium, bismuth, mercury	—	Graphite, graphitite	Iron, cobalt, nickel, platinum metals, diamonds
Equal	Iron	CaSO <sub>4</sub> , CaCO <sub>3</sub>	Copper, zinc, silver, cadmium, manganese, gold	—	Abioliths	—
Inferior	—	Sulphur, NaCl, KCl	Lead, BaSO <sub>4</sub> , phosphate	—	—	—
Very inferior or non-existent	Diamonds	—	Lithium, beryllium, boron, titanium, vanadium, niobium, molybdenum, tin, rare earths, tantalum, uranium, CaF <sub>2</sub>	Aluminium, manganese, iron, titanium, zirconium, tin, platinum metals, gold, clays, phosphate, CaCO <sub>3</sub> , SiO <sub>2</sub> , corundum, garnet	Coals, oil, asphalts, gas	—

biological factor on the Moon there may be fewer high grade organic deposits, although this trend may be partially or wholly counterbalanced by the higher overall percentage of carbonaceous matter and therefore the improved probabilities of the occasional concentration of carbonaceous matter through hydrothermal and volcanic processes. It is possible that the individual deposits have an evaporated or carbonized surface zone which may be underlain by a zone which is enriched with the products of distillation from the surface; this lower zone should also have a large hydrogen/carbon ratio.

Photographs from Surveyor spacecraft show that the lunar matter which was disturbed through the impact of one of the legs of the spacecraft was of a darker shade than the undisturbed powdery matter. This suggests either the efflorescences of salts on the surface or the leaching out of dark carbonaceous material from the surface through solar radiation. The second alternative would imply a lunar carbonaceous complex, which may originate from lunar dust, cosmic dust and carbonaceous meteorites.

**Impactites.** Because of the lack of an appreciable atmosphere the "impactites" on the surface of the Moon must be of greater importance than on the Earth. The abundance of nickel iron alloy present on the lunar surface is difficult to assess, but it may prove to be considerable. It is possible that after the impact of larger bodies secondary volcanism may bring some of the nickel iron from deeply buried impactites to the surface. Because impact on the Moon would liberate a considerable density of energy, minerals may be transformed by impact to high pressure forms unknown on Earth. The crust of the Moon may not contain diamonds but the meteoritic debris on its surface may provide a considerable source of industrial diamonds. In this connexion it may be noted that the impact of the siderites shocked by the Canon Diablo meteorite contains some 0.1 per cent of diamonds. This represents an approximate concentration 10<sup>4</sup> greater than in the richest hitherto known terrestrial concentrations from South Africa.

The systematic study of mineral deposits on the Moon should yield, in the foreseeable future, data of theoretical interest on the processes of crystallization of magmas

under gravitational fields of differing intensities and the comparison of redistribution of volatiles within celestial bodies of the mass of the Moon and the mass of the Earth. The effects of differing types of atmospheres and radiations on the zones of mineral deposits close to the surface could be studied as well.

The economic utility of the mineral deposits within the more distant future may primarily depend on how much the cost of trips to the Moon can be reduced, particularly through the advent of the atomic rocket. With the gradual exhaustion of the small number of top grade terrestrial deposits our mining techniques and metallurgy tend to become more and more adapted toward the exploration of lower grade and more extensive deposits. It may be that a considerable number of top grade deposits, including those of platinum metals, will be found on the surface of the Moon. Another potential economic advantage may be that the lunar deposits may, to some extent, compensate the terrestrial ones because of the different conditions which prevailed in the course of their genesis. For example, evaporite deposits on Earth contain chiefly sodium chloride while the deposits of the Moon may be predominantly magnesian.

Table 2 compares the suggested volume and grade of possible lunar deposits of the more important metals and non-metallic minerals, with their terrestrial genetical equivalents or quasi-equivalents.

I thank Dr Sidney W. Fox for fruitful conversations on the subject. This work was supported by the US National Aeronautics and Space Administration.

## Ice Front in the North Sea

by  
DEREK FLINN

The Jane Herdman Laboratories of Geology,  
University of Liverpool

Study of an arcuate belt of deeps with its apex to the north of Aberdeen leads to the suggestion that at the last glacial maximum Norwegian ice failed to cross the Norwegian Trench not far south of Bergen. This left an ice free area reaching across the North Sea to Scotland.

I AM constructing a bathymetric map of the continental shelf to the north of Britain. The area covered lies between 56° N., the continental slope to the west of Orkney and to the west and north of Shetland, and the western edge of the Norwegian trench. So far I have obtained about

20,000 miles of echo trace covering the area in a moderately uniform network.

Examination of these traces reveals that many of them cross deeps of a fairly well defined type, some examples of which are shown in Fig. 1. The profiles have been

redrawn from various echo traces to a common horizontal and vertical scale. The horizontal scale is based on Mercator's projection and so varies slightly from example to example. The vertical exaggeration is about  $\times 150$  and no correction has been made for error due to interaction between the slope of the sea floor and the conical form of the transmission beam of the echo sounder. With this vertical exaggeration, deeps of the type shown are easily distinguished from all other submarine valleys and show no gradation towards them. The characteristic feature of these deeps is the low width to depth ratio. The V-shaped cross-section is, in part at least, due to the uncorrected error mentioned. Another characteristic is that they are usually closed at either end with no sign of even a shallow channel like continuation.

Although echo traces from the whole of the continental shelf north of  $56^\circ$  N. and Cape Wrath were examined, these deeps were found only within the area of Fig. 2, that is to the east of Orkney, Moray Firth and Aberdeen. Within this area nearly all the deeps are concentrated in a narrow strongly arcuate belt with its apex to the north of Aberdeen. Deeply lying outside the belt are relatively small. Furthermore, all the deeps crossed by more than one echo trace (thus fixing their orientation) lie more or less parallel to radii of the arcuate belt. Many of the deeps crossed by only one echo trace may also have this orientation because they are found chiefly where echo traces run parallel to the belt.

Some of the deeps in Fig. 2 are well known by name—for example, Devil's Hole, Buchan Deep and the Fladen Ground Deep—but only the last appears to have been surveyed before the oil and gas exploration campaign. Similar but smaller deeps of the same type occur to the south of  $56^\circ$  N., and some have been surveyed. The characteristic cross section and closed ends have been described and various hypotheses offered to explain them<sup>1</sup>. At present, the most widely held view is that they formed under the front of an ice sheet as siphons through which melt water escaped under pressure.

Fig. 1. Uncorrected echo trace profiles of deeps. Vertical exaggeration  $\times 150$ .

- a,  $59^\circ 20' \text{ N.}$  b,  $59^\circ 29' \text{ N.}$  c,  $58^\circ 10' \text{ N.}$  d,  $57^\circ 50' \text{ N.}$   
 $00^\circ 35' \text{ E.}$   $02^\circ 00' \text{ E.}$   $00^\circ 50' \text{ E.}$   $01^\circ 45' \text{ W.}$   
e,  $59^\circ 10' \text{ N.}$  Fladen Ground Deep f,  $58^\circ 27' \text{ N.}$   
 $00^\circ 25' \text{ W.}$   $01^\circ 30' \text{ W.}$   
g,  $57^\circ 50' \text{ N.}$  Buchan Deep h,  $56^\circ 46' \text{ N.}$  Devil's Hole  
 $01^\circ 55' \text{ W.}$   $00^\circ 56' \text{ E.}$

If this hypothesis is correct, then the arcuate belt of deeps in the northern North Sea marks an ice front at some time in the past. The arrangement of the deeps in a belt and their radial orientation supports the ice front hypothesis. There is, however, nothing in what is at present known about the arrangement or the form of the deeps to show whether the ice free area lay inside or outside the arcuate belt.

In all the echo traces examined, only three showed penetration of the sea floor. Echo traces from two different ships showed penetration inside the arcuate belt (Fig. 2). In another echo trace made by one of the ships, penetration is shown in the belt and to the north. Although both ships cruised widely over the shelf they found no penetration elsewhere. A section of echo trace showing penetration of the sea floor, and redrawn to the same horizontal and vertical scales used in Fig. 1, is shown in Fig. 3.

The echo traces show that within the arcuate belt of deeps, in the deepest part, lies a pool of sediments deposited on a rough surface so as to level it. If the speed of sound in the sediments is about the same as in the overlying seawater, the sedimentary layer is about 18 m thick. In places the sediments fill minor deeps and are too thick to be completely penetrated by the echo sounder. Minor pools of sediment occur in the belt and to the north. In Fig. 2 a boundary has been drawn to the main pool, but this boundary is unreliable and is based only on unpublished bathymetric data.

Sediments transparent to echo sounder transmissions are usually mud. Chart No. 112 of the Deutsches Hydrographisches Institut reports a sea floor of mud in many places within the area delimited in Fig. 2 and very rarely outside it.

It is possible that the arcuate belt of deeps marks an ice front with the ice free area inside the arc. The water draining out of the ice deposited the suspended mud on the floor of the ice free area. An ice free area like this reaching across the North Sea to Scotland has not been predicted in any published reconstructions of Pleistocene ice sheets. The alternative, an ice tongue reaching across to Scotland with ice free areas to the north and south, would require the late sediments to have been deposited after the disappearance of the ice from the area. Thus there would be no known source for the late sediments, and no known reason for their present location and their absence from the rest of the North Sea.

The question arises as to whether the sediments were deposited on land or under water. They seem to have been deposited by distribution over the floor of the basin and not by settling from above, though this could have been done by subaerial streams or submarine gravity currents. If the topography of the area was exactly as it is at present, then there would have been at least 70 m of water because of a barrier to the east separating the region from the Norwegian trench. Tilting of the Earth's surface under the weight of the Scandinavian ice sheet could have lowered or even removed this barrier, allowing the melt water to escape if the ice bridged and did not entirely fill the Norwegian trench.

No ice free area such as that proposed has been predicted from glacial evidence on land, so it is not easy to relate this episode to glacial episodes known on land. It is clear that the ice front along the belt of deeps was part of a

major ice sheet and that no sheet formed since has been so extensive. The ice sheets formed in the various readvances recognizable in Scotland<sup>2</sup> were not of comparable size. It is possible that the deeps mark the ice front at or soon after the last glacial maximum. If before this and after the last interglacial, the ice sheet had completely covered the area, it would have had to melt away from most of the North Sea to be able to return and take up the position indicated by the deeps, for preferential melting of the ice sheet in this part of the North Sea area seems most unlikely. Alternatively, if as has been argued<sup>3</sup> no very extensive glaciation occurred in the last maximum the deeps must mark the ice front at the maximum before the last interglacial period.

If the arcuate belt marks the front of the last major ice sheet to occupy the area, it is of interest to study the evidence of the last major glaciation on the adjacent land masses. The nearest land to the ice free area, and lying partly within it, is the part of north-east Scotland between Aberdeen and the Moray Firth. This area has a complex glacial history<sup>3</sup>. It has suffered a number of glaciations and re-advances, but its most striking feature is "moraineless Buchan" (Fig. 4). The Buchan area is not free of moraine, but in it the moraine is so strongly weathered that it has been proposed that it belongs to a previous glacial maximum, was weathered in the last interglacial period and during the last glacial maximum was free of ice but suffered much frost shattering<sup>3</sup>. It

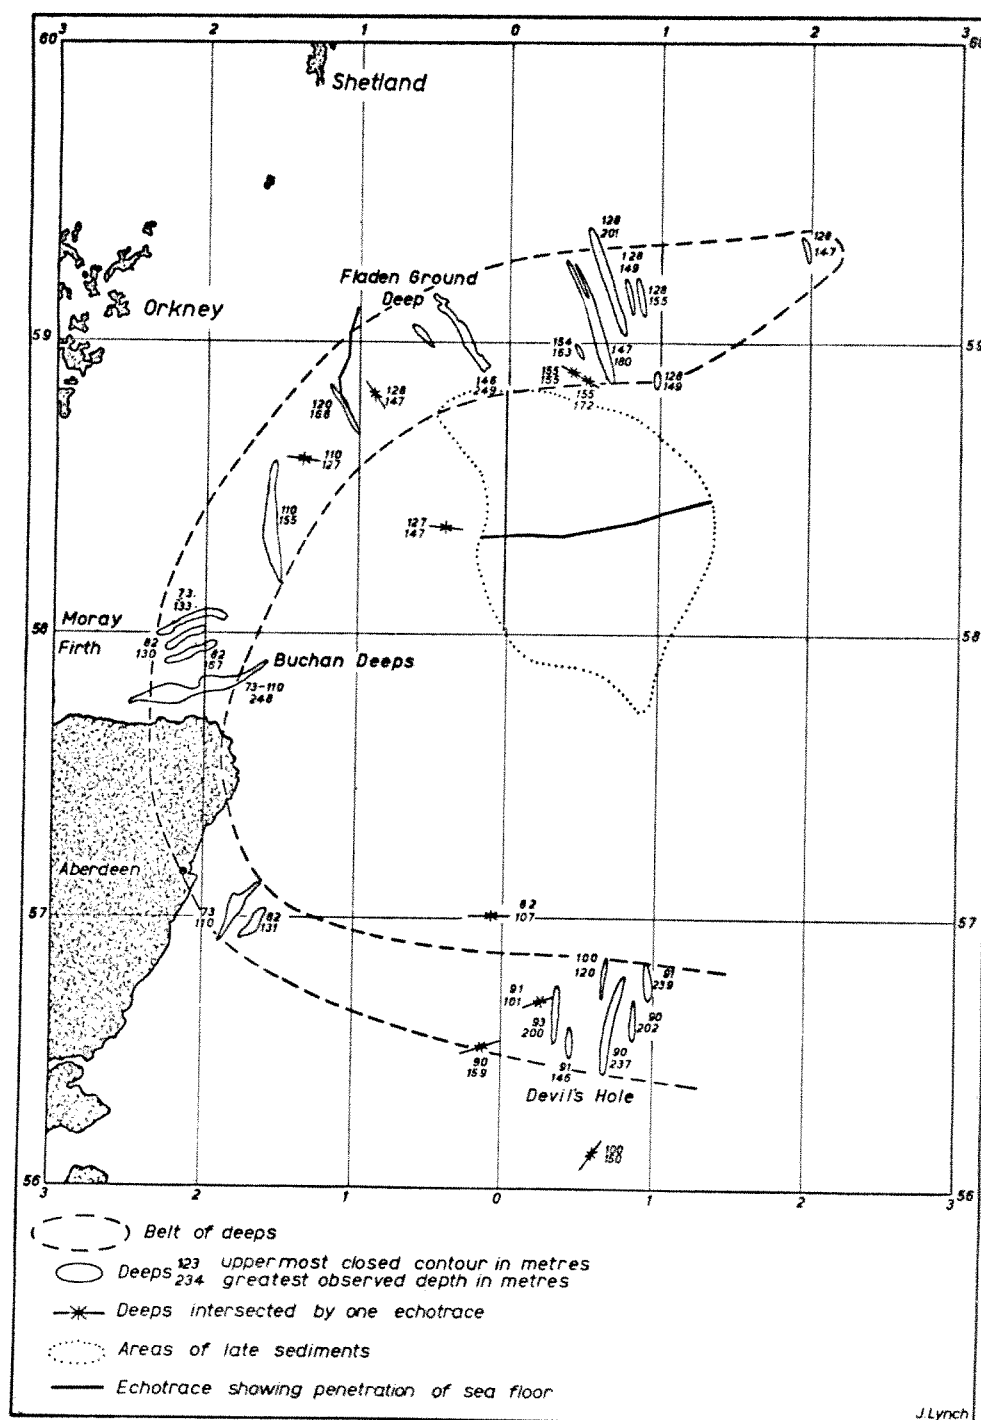

Fig. 2. Distribution of deeps and areas of late sedimentation in the northern North Sea.

Fig. 3. Echo trace made by R.V. Ernest Holt in 1964 showing penetration of the sea floor near the Fladen Ground Deep. Vertical exaggeration,  $\times 150$ .

requires only a relatively small extension to the south-east of the ice free area delimited by the belt of deeps to include "moraineless Buchan" and that extension would be on high ground which would tend to deflect ice flowing from the west.

The directions of ice flow determined from ice moulding, striae and erratics in Shetland are shown in Fig. 4 (unpublished work by Flinn and students). Contrary to Peach and Horne<sup>4</sup> the last major glaciation of Shetland was by a local ice cap<sup>5,6</sup>, but some of their evidence for ice sweeping over Shetland from the east is correct. In the extreme south some erratics have been carried over the watershed from east to west, but on the east side all the evidence is of ice moving to the east. In the extreme north (Unst) there is strong evidence of ice moving north-westwards and less

evidence of ice moving eastwards. In east central Shetland a very strong stream of ice flowed eastwards and then gradually swung north as it got further east. This deflection was probably due to pressure of Norwegian ice. The ice crossing Unst from the east may have been local ice or Norwegian ice.

A similar deflection in northern Scotland is believed to have occurred in the last glacial maximum<sup>7,8</sup>. Pressure of Scandinavian ice in the Moray Firth and to the north caused local Scottish ice flowing eastward into the Moray Firth to swing round and eventually flow north-westwards across Caithness and Orkney.

All this evidence is assembled in Fig. 4. It is proposed that in the last glacial maximum, Norwegian ice failed to cross the Norwegian Trench not far south of Bergen. Ice crossing to the north of this point flowed westwards and south-westwards across the shelf leaving a front along the northern arm of the arcuate belt of deeps. In the Shetland area, Norwegian ice was deflected to the north and south by a local ice cap but possibly overwhelmed the extremities in the early stages. In the area east of Orkney, the ice came into contact with Scottish ice and both sheets were deflected so as to flow north-westwards across Caithness and Orkney. Ice filled the Moray Firth but did not quite cover the north-east tip of Scotland. To the south of Aberdeen, Scottish ice flowed out into the North Sea leaving a front from near Aberdeen to the Devil's Holes. From there the front may have continued south to the Dogger Bank area where the front of the ice at its maximum extent in the last glacial maximum has been recognized<sup>9</sup>.

During the bathymetric survey no submarine moraines have been recognized either as topographic features or as stony grounds<sup>10</sup>.

I thank Dr J. B. Hersey of Woods Hole Oceanographic Institute, who supplied copies of echo traces made by R.V. Chain in 1963; Mr A. J. Lee of the Fisheries Laboratory, Ministry of Agriculture, Fisheries and Food, Lowestoft, who supplied echo traces made by R.V. Ernest Holt in 1963 and 1964; and NERC (and DSIR) for providing a grant which enabled me to process the echo traces.

Received April 19, 1967.

## LETTERS TO THE EDITOR

## ASTRONOMY

## Fluctuations in the Primordial Fireball

ONE of the overwhelming difficulties of realistic cosmological models is the inadequacy of Einstein's gravitational theory to explain the process of galaxy formation<sup>1-6</sup>. A means of evading this problem has been to postulate an initial spectrum of primordial fluctuations<sup>7</sup>. The interpretation of the recently discovered 3° K microwave background as being of cosmological origin<sup>8,9</sup> implies that fluctuations may not condense out of the expanding universe until an epoch when matter and radiation have decoupled<sup>4</sup>, at a temperature  $T_D$  of the order of 4,000° K. The question may then be posed: would fluctuations in the primordial fireball survive to an epoch when galaxy formation is possible?

Misner<sup>10</sup> has recently pointed out that fluctuations ranging in size from a photon mean free path up to the event horizon will be damped out by neutrino viscosity during the  $10^{10}$ – $10^{11}$  °K epochs. At  $10^{10}$  °K, however, the event horizon contains only  $10^{-4} M_\odot$  in a small amplitude ( $\delta\rho/\rho \ll 1$ ) fluctuation. The purpose of this communication is to demonstrate that a considerably more significant upper limit may be obtained by considering the effects of radiative diffusion on opaque fluctuations at subsequent epochs.

Over the temperature range  $10^{10}$  °K  $> T > T_D$ , the maximum mass  $M_T$  contained in a transparent fluctuation (that is, of scale  $\sim (\kappa\rho)^{-1}$ ) is

$$\frac{4}{3} \pi \kappa^{-3} \rho^{-2} \simeq 2.3 \times 10^{-29} \rho_0^{-2} T^{-6} M_\odot$$

where  $\kappa$  is the opacity, assumed to be due to Thomson scattering by free electrons, and  $\rho_0$  is the mean density of matter at the present epoch. In deriving this expression, we have assumed that the present value of the background radiation temperature is 3° K, and have used the relation  $\rho T^{-3} = \text{constant}$ . We consider initial fluctuations  $> 10^{-4} M_\odot$ , so that at some epoch subsequent to  $T = 10^{10}$  °K these fluctuations are encompassed within the event horizon. Indeed, the number of baryons corresponding to a galaxy cluster of  $\sim 10^{15} M_\odot$  is first contained within the event horizon at an epoch when  $T \simeq 10^{15} \rho_0^{1/3}$  °K. At this temperature,  $M_T \simeq 10 M_\odot$ , so that fluctuations of galactic dimensions are highly opaque.

We treat the damping of opaque fluctuations by radiative diffusion in the Newtonian approximation (an adequate approximation provided  $aT^4 \ll \rho c^2$ , where  $a$  is the radiation density constant, and equals  $7.6 \times 10^{-15}$  erg cm<sup>-3</sup> deg<sup>-4</sup>). The relevant equations are the equation of continuity

$$\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0$$

the equation of motion

$$\frac{d\mathbf{u}}{dt} = \nabla \varphi - \frac{1}{\rho} \nabla p$$

Poisson's equation

$$\nabla^2 \varphi = -4\pi G \rho$$

the energy equation

$$\rho \frac{d}{dt} \left( 3 \frac{kT}{m_p} + \frac{aT^4}{\rho} \right) - \frac{p}{\rho} \frac{d\rho}{dt} = \frac{c}{3} \nabla \cdot \left\{ \frac{1}{\kappa \rho} (\nabla aT^4) \right\}$$

and the equation of state

$$p = \frac{2\rho kT}{m_p} + \frac{1}{3} aT^4$$

This set of equations is linearized about the zeroth order solution (corresponding to an isotropic, homogeneous, expanding cosmological model of arbitrary curvature)

$$\mathbf{u} = \mathbf{r} \frac{\dot{R}}{R}, \quad \rho R^3 = \text{constant}, \quad \frac{\ddot{R}}{R} = -\frac{4\pi\rho G}{3}, \quad TR = \text{constant}$$

where  $R = R(t)$ ,  $\rho = \rho(t)$ . If we assume in addition that the perturbation may be expanded in plane waves of the order of  $\exp(i\mathbf{n} \cdot \mathbf{r})$  and that the heat capacity of the radiation greatly exceeds that of the matter, we obtain

$$\frac{\partial^2 s}{\partial t^2} + 2 \frac{\dot{R}}{R} \frac{\partial s}{\partial t} - \left( 4\pi G \rho - \frac{kT}{m_p} \frac{4\pi^2}{\lambda^2} \right) s = -\frac{4aT^3}{3\rho} \frac{4\pi^2}{\lambda^2} T_1 \quad (1)$$

and

$$\left( \frac{\partial}{\partial t} + \frac{c}{3\kappa\rho} \frac{4\pi^2}{\lambda^2} \right) \frac{T_1}{T} = 1/3 \frac{\partial s}{\partial t} \quad (2)$$

where  $T_1$  is the temperature perturbation,  $s$  is the relative density perturbation ( $= \rho_1/\rho$ ) and  $\lambda = 2\pi n/R$  is the co-moving wavelength. For the optically thin case ( $T_1/T \ll 1$ ) the usual Jeans criterion is recovered<sup>2,4</sup>; that is, for instability we must have

$$\lambda > \left( \frac{2\pi kT}{m_p G \rho} \right)^{1/2}$$

In the optically thick limit, however, it can readily be shown by an asymptotic treatment of equations (1) and (2) that the dominant mode in  $s$  is damped on a time-scale

$$t_d \sim 5 \frac{\kappa \rho}{c} \frac{\lambda^2}{4\pi^2}$$

We shall apply this result to two models; one with  $\rho_0 = 3 \times 10^{-29}$  g/cm<sup>3</sup>, corresponding to an Einstein-de Sitter universe, and the other with  $\rho_0 \simeq 10^{-30}$  g/cm<sup>3</sup>, corresponding to an open universe of mean density consistent with observation<sup>11</sup>.

For an Einstein-de Sitter universe, the expansion time is approximately given by  $t \simeq 1.6 \times 10^{18} T^{-3/2}$  sec, leading to

$$t_d/t = 2.2 \times 10^{-9} M_\lambda^{2/3} T^{5/2} \rho_0^{1/3}$$

where  $M_\lambda = 4/3 \pi \rho \lambda^3$  is the mass contained in a small ( $\rho/\rho_0 \ll 1$ ) fluctuation. It follows that opaque fluctuations containing up to about  $10^{12} M_\odot$  are damped (that is,  $t_d/t \ll 1$ ). In other words, any primordial fluctuation of cosmological significance must be at least of proper diameter  $\lambda$  (where  $M_\lambda \simeq 10^{12} M_\odot$ ) at the decoupling epoch, when galaxy formation may occur. Now the angular diameter subtended by a fluctuation of proper diameter  $\lambda$  is  $H_0 \lambda z_D / 2c$ , where  $z_D$  is the value of the red-shift at decoupling, and  $H_0$  is the present value of Hubble's constant. We know that  $1 + z_D \simeq T_D/3 \simeq 1.33 \times 10^3$ , and taking  $H_0 = 100$  km/sec/Mpc, we find that the angular diameter of a primordial fluctuation must be about half of a minute of arc.

In the case of an open universe, the expansion proceeds approximately linearly with time, and one has the relation  $t \simeq 1.2 \times 10^{18} T^{-1}$  sec. Therefore

$$t_d/t = 2.9 \times 10^{-9} M_\lambda^{2/3} T^{3/2} \rho_0^{1/3}$$

and it follows that the critical mass for a fluctuation to survive into an epoch when galaxy formation is possible is about  $3 \times 10^{13} M_\odot$ . One may then show\* that this corresponds to an angular diameter of at least one minute of arc.

\* For large  $z$ , the angular diameter of a source of proper diameter  $\lambda$  in an open cosmological model (with zero cosmological constant and  $p \simeq 0$ ) is given approximately by the expression

$$\frac{z}{c} \frac{\lambda \sqrt{8\pi G \rho_0}}{3} \frac{1}{\sinh \left\{ \frac{2}{H_0} \sqrt{\frac{8\pi G}{3} \rho_0} \ln \sqrt{\frac{2}{\sigma_0}} \right\}}, \quad \text{where } \sigma_0 = \frac{4\pi G \rho_0}{3H_0^2}$$

Measurement of the isotropy of the 3° K cosmic microwave background sets an upper limit on the scale and amplitude of fluctuations at the epoch when matter and radiation decouple. Indeed, angular variation in 3° K background is due essentially to intrinsic variations in the decoupling temperature, provided that no significant density fluctuations occur in the universe on a scale much greater than 1 Mpcsec<sup>6</sup>.

A recent observation<sup>12</sup> on the isotropy of the 3° K background radiation at a frequency of 10,690 Mc/s implies that the background radiation over a right ascension interval of about 4 h is structureless to less than 0.02 per cent on an angular scale of about 1°. Angular resolution of one minute of arc or better, however, is required in order to detect primordial inhomogeneities. When observations at this resolution are forthcoming, it should be possible to answer the question of whether or not galaxies may have formed from fluctuations present *ab initio*. Dr J. P. Wright has suggested to me that another critical factor in interpreting the anisotropy limit will be the mean separation distance between coherent fluctuations at decoupling. A linearized treatment does not allow such considerations; however, our calculation sets an upper limit to the scale of anisotropy expected from primordial fluctuations.

### Friedmann Cosmological Model with both Radiation and Matter

THE discovery<sup>1</sup> and investigation<sup>2,3</sup> of the cosmic black-body radiation have opened the door to fairly reliable calculations of such evolutionary phenomena as the temperature-density history of the universe, primordial element formation<sup>4</sup>, expansion anisotropy<sup>5</sup> and galaxy formation<sup>6</sup>. The isotropy of this radiation<sup>3,5</sup> supports the current practice of idealizing the universe as spatially homogeneous and isotropic and as filled with pressureless matter and isotropic radiation.

In this standard model of the universe the radiation dominates for roughly the first 2,000 years of evolution, and the matter predominates thereafter. Until now, such cosmological models have been studied numerically or by joining a radiation universe,  $p = \rho/3$ , to a matter universe,  $p = 0$ , smoothly at some particular time. (I choose throughout that  $c = G = 1$ .) I am aware of only one analytical solution to the Einstein field equations for a universe filled with radiation and matter, and we shall see that this solution<sup>7</sup> is physically unsatisfactory.

This communication presents a new<sup>8</sup> analytical solution to the cosmological model containing both radiation and matter. The assumptions of this model are: (1) spatial homogeneity and isotropy with the flat Friedmann line element

$$ds^2 = dt^2 - R^2(t) [dx^2 + dy^2 + dz^2] \quad (1)$$

Fig. 1. Comparing the observables,  $\rho_M/\rho_{M0}$ , matter mass-density,  $\rho_R/\rho_{M0}$ , radiation mass-density, and  $q$ , deceleration parameter in the new solution (1), in the standard radiation-universe-joined-to-matter-universe solution (2), and in McIntosh's solution (3). The normalizing factors are  $\rho_{M0} = 2.3 \times 10^{-29}$  g cm<sup>-3</sup> and  $\tau = 5.9 \times 10^8$  years.

(2) a stress-energy with both pressureless matter, of mass-density  $\rho_M$ , and isotropic radiation, with pressure  $p_R = \rho_R/3$ ; and (3) independent, adiabatic expansion of the radiation and matter with negligible interchange of energy between them

$$\rho_M = \rho_{M0} (R/R_0)^{-3}, \quad \rho_R = \rho_{R0} (R/R_0)^{-4} \quad (2)$$

A subscript zero denotes the value of a quantity today. If the universe is spatially homogeneous, isotropic and Euclidean this model should be an excellent approximation from about 20 sec after creation, when the thermal electron energies become non-relativistic, until today. Under these assumptions the Einstein field equations, with zero cosmological constant, become

$$3 (\dot{R}/R)^2 = 8\pi (\rho_M + \rho_R) \quad (3)$$

$$2 (\ddot{R}/R) + (\dot{R}/R)^2 = -8\pi p_R$$

The chief result of this communication is the following analytical solution to equations (2) and (3)

$$t/\tau = [(R/R_0) - 2S_0] [(R/R_0) + S_0]^{\frac{1}{2}} + 2S_0^{\frac{3}{2}} \quad (4)$$

where

$$\tau \equiv (6\pi \rho_{M0})^{-\frac{1}{2}}, \quad S_0 \equiv \rho_{R0}/\rho_{M0} \quad (5)$$

The Hubble expansion rate and deceleration parameter are

$$H \equiv (\dot{R}/R) = (2/3\tau) (R/R_0)^{-2} [(R/R_0) + S_0]^{\frac{1}{2}} \quad (6)$$

$$q \equiv -\ddot{R}/(RH^2) = \frac{1}{2} [(R/R_0) + 2S_0] [(R/R_0) + S_0]^{-1} \quad (7)$$

and the total mass-density and pressure are

$$\rho_T \equiv \rho_M + \rho_R = \rho_{M0} (R/R_0)^{-4} [(R/R_0) + S_0] \quad (8)$$

$$p_T \equiv p_R = \rho_{M0} (S_0/3) (R/R_0)^{-4} \quad (9)$$

The observed Hubble expansion rate today<sup>9</sup>,  $H_0^{-1} = (8.8 \pm 1.6) \times 10^9$  years, and the observed temperature,  $3.0 \pm 0.5$  °K, of the cosmic black-body radiation determine the constants

$$\begin{aligned}\tau &= (5.9 \pm 1.0) \times 10^9 \text{ yrs} \\ S_0 &= \left(2.9 + \frac{5.4}{-1.8}\right) \times 10^{-2} \\ \rho_{M_0} &= (2.3 \pm 0.8) \times 10^{-23} \text{ g cm}^{-3} \\ \rho_{R_0} &= \left(6.8 + \frac{5.6}{-3.3}\right) \times 10^{-24} \text{ g cm}^{-3}\end{aligned}$$

In Fig. 1 we compare this new solution (1) with (2) the standard solution, in which a matter universe is joined smoothly, both  $R(t)$  and  $H(t)$  continuous, to a radiation universe when  $\rho_R \equiv \rho_M$

$$R/R_0 = \left\{ \begin{aligned} & (16 S_0/9)^{1/3} (t/\tau)^{1/3} \\ & [(t/\tau) + \frac{1}{4} S_0^2]^{1/3} \end{aligned} \right\} \text{ for } (t/\tau) \begin{matrix} \leq \frac{3}{4} S_0^2 \\ > \frac{3}{4} S_0^2 \end{matrix} \quad (10)$$

and (3) the solution of McIntosh<sup>8</sup> derived from

$$\log R(t) = 2 \int [3t + \beta^{-1} (1 - e^{-\beta t})]^{-1} dt + \text{constant} \quad (11)$$

The quantities  $H/H_0$  and  $\rho_M/\rho_{M_0}$  are essentially identical in all three models. The differences between McIntosh's model and the other two are most apparent in the observables  $\rho_M/\rho_{M_0}$ ,  $\rho_R/\rho_{M_0}$ , and  $q$ . Note that McIntosh's model enters the matter universe about a quarter billion years after creation, while the other two models become dominated by matter after only 2,000 years of evolution. During the period of cosmic nucleosynthesis, when  $R/R_0 \approx 10^{-8}$ , the matter density in McIntosh's model is  $10^9$  times smaller than in the other models.

## Nine Million Wavelength Baseline Interferometer Measurements of 3C 273B

OBSERVATIONS on the angular dimensions of the variable radio source 3C 273B by Palmer *et al.*<sup>1</sup> using effective baselines of up to 2 million wavelengths have reduced the upper limit on its angular size to 0.025 sec of arc at a wavelength of 6 cm. A recent observation using a trans-Canadian baseline indicates that the source is unresolved at an operating frequency of 600 Mc/s and an effective baseline of 6 million wavelengths.

Predicted values of the angular dimensions of radio sources are based on Le Roux's model<sup>2</sup>. It is desirable to test the applicability of this model to variable sources exhibiting flat spectra in view of the cosmological implications which may be drawn from their dimensions.

In January 1967 we attempted to operate two of the NASA Deep Space Stations in Australia as an intensity interferometer<sup>3</sup> of exceptionally high resolution. The two stations were located at Island Lagoon, 12 miles south of Woomera and at Tidbinbilla, about 35 miles from Canberra. This gave a baseline of more than  $9 \times 10^6$  wavelengths at our operating frequency of 2,295 Mc/s. Signals from source 3C 273 were recorded in analogue

form together with appropriate timing codes derived from rubidium frequency standards. This attempt failed because of difficulties associated with subsequent analogue to digital conversion.

In early June the experiment was repeated, but this time the data were recorded in digital form at the two stations using analogue to digital converters controlled by SDS920 computers. The sampling rate (1 kc/s) was controlled by rubidium frequency standards at both stations, and sampling began at predetermined times. It is not possible to synchronize starting times accurately because of a small time difference between the station clocks that control the computers. These computers were programmed so as to sample for 96 sec every 2 min. For the remaining 24 sec the computers provided antenna pointing error information.

The pairs of tapes from the station computers were correlated in Adelaide, using the University of Adelaide computer (CDC 6400). The correlation coefficient  $\rho_r$  was computed, where

$$\rho_r = \frac{\sum_{N=r}^N X_N \cdot Y_{(N-r)}}{\left[ \sum_{N=r}^N X_N^2 \right]^{1/2} \left[ \sum_{N=r}^N Y_{(N-r)}^2 \right]^{1/2}}$$

$\rho_r$  is thus the correlation coefficient for a slip of  $r$  data points between  $X$  and  $Y$  and the data samples from the two stations.  $\rho_r$  corresponds to  $C(1, t)$  or  $\rho^2(1)$  of ref. 3.

The signal to noise ratio at the output of the square law detectors was extremely low ( $< 0.06$ ), so that the maximum possible value of  $\rho_r$  was  $4 \times 10^{-3}$ , assuming that 3C 273B has a strength of 25 flux units.

The correlogram in Fig. 1 required  $3.16 \times 10^6$  data samples from each station, which corresponds to nearly an hour of observing time. During this time the effective baseline varied between  $7.8 \times 10^6$  and  $9.1 \times 10^6$  wavelengths because of the rotation of the Earth. The observed peak value of the correlation coefficient ( $2.5 \times 10^{-3}$ ) is considerably less than its predicted maximum value ( $4 \times 10^{-3}$ ) for an unresolved source.

Except at the zenith, there is a difference in time of arrival of the signals at the two stations. This difference in arrival time is not constant. It changes with the orientation of the baseline at a rate of up to 1 msec/h when the source is near the zenith. This causes a time slip between the two sets of data which varies at the same rate. The sampling rate is one sample/msec so that continuous compensation for this slip is not possible without interpolation between samples. This was not done and we estimate the penalty to have been a 20 per cent reduction in the correlation peak.

In Fig. 1 time slips due to changing baseline orientation between observations were removed by slipping the sets of data by appropriate amounts. If the clocks at the two stations had been in synchronism, the correlation peak would have coincided with the  $Y$  axis. The difference between the clocks in milliseconds is equal to the displacement of the peak from the  $Y$  axis. In this instance it is about 2.5 data points, that is, 2.5 msec.

In addition to variations in time slip during observations, the correlation peak is very sensitive to signal strength changes such as those resulting from antenna pointing errors. A fall of 1 dB in signal strength at both antennas degrades the correlation peak by 4 dB.

The post detection bandwidth (400 c/s) was dictated by the availability of suitable filters, and the ratio of sampling speed to bandwidth is uncomfortably low. Under such conditions the correlation peak contains few points, and the determination of its amplitude is difficult. Faster sampling rates may be available in future.

There is some evidence of reduced correlation when the effective baseline exceeds  $8 \times 10^6$  wavelengths but, in view of the known sources of correlation loss, the observed

peak value of  $(2.5 \times 10^{-3})$  is not inconsistent with a totally unresolved source, that is, a source with an angular dimension less than 0.008 sec of arc.

In general, it was necessary to combine the results of a number of observations in order to produce a correlation peak that rose significantly above the noise. One exception was a 15 min ( $88 \times 10^4$  samples) observation at  $7.8 \times 10^6$  wavelengths. This is shown in Fig. 2. It is one of the results used in Fig. 1, and was apparently a period in which antenna pointing errors were negligible.

The direction of the measured dimension across the source varies with its hour angle. Measured from the axis of the Earth in a clockwise sense, this direction lay exclusively in the second quadrant. The results quoted here refer to orientations of the measured dimension between  $108^\circ$  and  $110^\circ$ .

The system we have used is applicable to any pair of stations in the Deep Space Network. At the moment these stations have duplexers, etc., in their antenna feeds. This causes a signal loss of at least 3 dB, or a reduction in the correlation peak of 12 dB.

The position of the correlation peak gives the difference between the clocks of the two stations. This provides a new method of comparing widely separated clocks. The accuracy of the measurement depends on the post detection bandwidth and the sampling speed. For example, a

20 kc/s post detection bandwidth with a 100 kc/s sampling rate should provide an accuracy of at least 10  $\mu$ sec.

Nearly an order of magnitude improvement in the resolution afforded by the Australian-based Deep Space Station pair can be obtained by using two or more DSS stations on different continents. Thus identical procedures may be applied to any such pair to ascertain whether the angular dimensions are compatible with the period of variation and the red-shift of the source.

We thank the staffs of both stations for their help, particularly A. J. Legg of DSS 41, who wrote the programme for the station computers. We also thank J. N. Weadon of the University of Adelaide for writing the correlation programme for the CDC 6400. The use of the stations was by kind permission of the US National Aeronautics and Space Administration and the Jet Propulsion Laboratories.

### NGC 5189 and the CRUX X-ray Source

Of the objects in the southern hemisphere which are generally classified as planetary nebulae<sup>1</sup> undoubtedly the two with the most strikingly anomalous forms are NGC 6302 (refs. 2, 3) and NGC 5189 (refs. 4, 5). Attention has been drawn by Minkowski and Johnson to the fact that NGC 6302 lies close to the position of the cosmic X-ray source SCO XR-2. It is interesting therefore that NGC 5189 ( $13.5h-65^\circ.7$ ) lies in the direction of the X-ray source CRUX recently discovered by Harries *et al.*<sup>6</sup>. The uncertainty in the position of this source is considerable (especially in declination), two measures giving  $13.7h-62^\circ$  and  $13.5h-66^\circ$ . Thus clearly no positive identification can yet be claimed. Nevertheless, in view of the small number of known X-ray sources it seems quite remarkable to find even approximate agreement in positions between two of them and two such highly peculiar objects as NGC 5189 and NGC 6302 unless there is indeed some physical connexion.

### PLANETARY SCIENCE

#### Molecular Fluorescence accompanying the Twilight Injection of Triethylborane into the Upper Atmosphere

A RECENT note<sup>1</sup> described the yellow-green fluorescence which resulted from the injection of triethylborane into the upper atmosphere. At that time, the radiating species which produced this fluorescence was not identified, and

a spectrum has since been obtained from a similar release of triethylborane.

Originally, a boron compound was chosen in an attempt to produce boron monoxide in the upper atmosphere. The attempt to form boron monoxide had a dual purpose: to determine temperature from the fluorescence spectra and compare this with temperature obtained from aluminium oxide; and to obtain a material with a molecular weight more nearly equal to the average molecular weight of the atmosphere. The latter would allow more reliable diffusion data to be obtained than from a release of trimethyl aluminium.

Because no spectra were obtained in the first experiment<sup>1</sup>, the experiment was repeated. The object of the second experiment was to identify the radiating species from the molecular fluorescence spectrum, and at the same time to obtain data on the upper atmospheric wind from the motion of the released material.

Fig. 1. Spectrum obtained from the sunlit release of triethylborane at height between 90 km and 178 km.

A two-stage Nike-Cajun rocket system was used to disperse 6.2 kg of triethylborane above the Sandia Corporation launch site at Kauai, Hawaii. Payload characteristics including orifice diameters and nitrogen pressure were the same as reported in ref. 1. The rocket was launched on June 2, 1967, at 1947 Hawaii standard time or on June 3 at 0547 GMT. Liquid triethylborane was continuously ejected, beginning at 90 km on the ascent and continuing through apogee at 178 km. The depression angle of the Sun at launch was  $\approx 7^\circ$  and the shadow of the Earth was at 30 km above the site.

Low resolution spectra were obtained using a photographic spectrograph with an effective aperture of  $f/0.87$  and a reciprocal linear dispersion of 208 Å/mm. Spectra were recorded on calibrated Eastman Kodak spectroscopic plates. A spectrum obtained from the sunlit release of triethylborane is shown in Fig. 1. The observed bands have been identified as the  $A^2\pi \rightarrow ^2\pi$  transition of boron oxide.

The most pronounced difference between this spectrum and published low dispersion spectral data<sup>2</sup> on boron oxide is the absence of the band at 6025 Å.

The molecular fluorescence spectrum obtained from a sunlit release of triethylboron has been identified as due to boron oxide. This molecule is not suitable for temperature measurement and is no better than aluminium oxide for obtaining diffusion data.

## PHYSICS

### Barrier to Coalescence in Stabilized Emulsions

ALTHOUGH emulsions of immiscible liquids are thermodynamically unstable, it is well known that the rate of coalescence may be reduced by adding small quantities of a third component (stabilizer) which is tensioactive. Many theories have tried to explain emulsion stability but none has been perfectly general. The most general theory is based on the stabilization of thin liquid films during approach of droplets as a result of the Gibbs-Marangoni effect<sup>1</sup>. This stabilizing effect may operate during the early stages of emulsion formation. Electrical repulsion must be a barrier to coalescence in emulsions stabilized by ionized detergents<sup>2</sup>, but many emulsions of high stability may be prepared in which no electrical potential barrier is believed to be present. The purely hypothetical "solvation barriers"<sup>3</sup> cannot explain the stability of water/oil emulsions where the oil is a paraffin, for example, in which no orientation at the interfaces would be expected. A barrier resulting from the high viscosity of the stabilizing film<sup>4</sup> cannot account for the high stability of emulsions stabilized by monolayers which do not increase the interfacial viscosity. The difficulty of flow of the continuous medium from thin films between approaching droplets results in a hydrodynamic barrier which would not be expected to be influenced very greatly by the presence of adsorbed monolayers. These latter two mechanisms do not offer an explanation of emulsion type.

If we consider the change in free energy of a system of two droplets during the process of coalescence in the presence of a third adsorbed component, we see immediately a mechanism which will tend to produce a barrier to coalescence. The coalescence of two droplets with no adsorbed substance at their interface proceeds with a decrease in free energy because the product  $\gamma A$  decreases as a result of the decrease in interfacial area ( $A$ ), the interfacial tension ( $\gamma$ ) remaining constant. With an adsorbed third substance, however, the interfacial tension may change if the rate of decrease of interfacial area is fast in comparison with the rate of desorption of the third component. It will produce a temporary displacement of the adsorption equilibrium. The chemical potential of the stabilizer in the interface is raised as a result of the compression, and it will attempt to return to its equilibrium interfacial pressure ( $\pi$ ), which it can only do by desorption or increasing the interfacial area. The compression of the monolayer in this manner produces an elastic restoring mechanism which tends to oppose coalescence.

When two droplets of radius  $0.1\mu$  coalesce, there is a decrease in interfacial area of the order of  $10^{-10}$  cm<sup>2</sup>. If the average increase of  $\pi$  during coalescence is 1 dyne/cm, the work required for compressing the monolayer ( $\int \pi dA$ ) is of the order of  $10^4 kT$ . It might appear that this mechanism would produce emulsions of greater stability and that the size of the barrier would increase with increasing size of droplets. It is, however, probable that the transition complex<sup>5</sup> corresponds only to an initial critical stage in the compression. Once a sufficiently large opening is made in the droplets, the coalescence

will proceed spontaneously. Moreover, there are two factors which will tend to lower the energy barrier as the droplet size is increased. First, for equal rates of compression ( $dA/dt$ ), the rate of increase of  $\pi$ , ( $d\pi/dt$ ), will be less for a large interface than a small one, because  $d\pi/dA$  is inversely proportional to  $A$  (the compressibility  $1/A \, dA/d\pi$  being constant). Second, the rate of decrease of interfacial area ( $dA/dt$ ) would be expected to be less for two large drops coalescing if we consider the average kinetic energy of the droplets ( $\frac{1}{2}mv^2$ ) to be constant, thus allowing more time for desorption. We conclude that for a given system, there will be an optimum droplet size which will produce a maximum barrier to coalescence. This is generally confirmed in practice for the mean particle size usually becomes stabilized during formation of emulsions.

An empirical rule which appears to be very general for the prediction of emulsion type is that the phase in which the stabilizer is more soluble becomes the continuous phase<sup>6</sup>. Thus, on the basis of the present model, when two droplets collide in a system in which the stabilizer is soluble in the dispersed phase, the adsorbed stabilizer near the point of collision is free to desorb and diffuse away into the droplets whereupon coalescence may occur more easily. On the other hand, when the stabilizer is soluble in the continuous phase, the adsorbed stabilizer near the point of collision is prevented from desorbing and diffusing away because of the displacement of the diffusion medium in this region (see Fig. 1). It must therefore remain in the interface, tending to give rise to a sudden increase in the interfacial pressure of the adsorbed monolayer.

The choice of stabilizers is usually made by a trial and error procedure, but on the basis of the model it is possible to predict fairly accurately the efficiency of a particular stabilizer (see, however, Davies, J. T., *Proc. 2nd Int. Cong. Surface Activity*, 1, 426 (London, 1957)). In principle, it is possible to map the energy barrier to coalescence for a given system. For this, we require to know the time rate of change of the interfacial area during coalescence; the equilibrium adsorption isotherm ( $\gamma$ - $C$ ) and  $\pi$ - $A$  relationships of the monolayer substance; and the rate of desorption of the monolayer as a function of  $\pi$  and time.

Although the energy barrier must be assessed for the particular system studied, some general predictions may be made on the basis of the model.

In order to produce high stability, a stabilizer should have a high free energy of adsorption. This is because for equal increments in  $\pi$  above its equilibrium value, a stabilizer with a high free energy of adsorption will

produce smaller concentration gradients near the surface than a stabilizer with a low free energy of adsorption. For high stability, the monolayer of the stabilizer should have as low a compressibility as possible. Any factor which reduces the rate of desorption of the monolayer should increase the stability. Hindered desorption has previously been suggested to be important in stabilizing of emulsions<sup>7</sup>. Thus high viscosity of the continuous phase would contribute to an increase in the size of the coalescence barrier as well as increasing the stability by reducing the frequency of collision of droplets. Strong agitation of the emulsion would contribute to lower stability because it would tend to eliminate the diffusion barrier to desorption. In the case of ionized stabilizers, the rate of desorption may be considerably reduced by addition of non-ionic surface active agents which lower the electrical potential and therefore the chemical potential of the stabilizer in the interface. Thus the efficiency of alkyl sulphates as stabilizers is greatly increased by the presence of alcohols and other non-ionic surfactants<sup>8</sup>.

It should prove interesting to compare values of the energy barrier calculated on the basis of this model with values determined experimentally from emulsion stability measurements. Unfortunately, few reliable experimental values are available<sup>9</sup>.

## Temperature of a Moving Body

LANDSBERG<sup>1,2</sup> has raised the question of the correct definition of temperature in relativistic thermodynamics. He advances<sup>3</sup> a general case against the orthodox transformation of temperature by considering the case of two systems, possessing equal proper temperatures,  $T_0$ , and in relative motion. Then observers moving with the two systems will each judge the temperature of the other system to be lower than that of the system with which he is moving. If the usual relation exists between temperature difference and heat flow, both proper temperatures should fall, a conclusion Landsberg finds unacceptable. The argument is not, however, completely convincing, and Williams<sup>4</sup> has pointed out that the direction of energy flow between two systems is, in general, dependent on the frame of reference in which the flow is observed.

Landsberg's example can be examined in the following manner. Observations made in the C.M. frame of system A show that the moving system B has a temperature of  $T_0/\beta < T_0$ , according to the orthodox transformation. Hence in this frame the system A should lose energy, and its temperature should fall, while system B should gain energy and its temperature should rise to  $T' > T_0/\beta$ . It follows then that the proper temperature of B should rise to  $\beta T' > T_0$ , unless the factor  $\beta$  has decreased to such an extent that  $\beta < T_0/T'$ . Landsberg does not examine this possibility. If, however, one requires that each system

Fig. 1. Transition complex in coalescence. a, Stabilizer soluble in continuous phase; b, stabilizer soluble in dispersed phase. A, B, Initial and final states in coalescence. Hatched area, critical work of compression of monolayer. - - - - , Diffusion layer.

remains at rest in its own C.M. frame when it acquires purely thermal energy, then  $\beta$  is unchanged by the process. If the process is now examined from the C.M. frame of  $B$  one will have to conclude that the proper temperature of  $B$  should fall. It is unacceptable that one should be able to deduce that the proper temperature of  $B$  will either rise or fall according to the frame of reference in which one chooses to examine the process.

Williams's objection to Landsberg's argument fails in this case because the two systems are required to remain at rest in their respective C.M. frames. Consequently, the sign of the energy gained by either system is invariant to a Lorentz transformation and hence the direction of energy flow is invariant. This can be seen as follows. If a system suffers a change in its energy momentum four vector of  $(c \overline{dP}, dE)$ , then the value of  $(c^2 dP^2 - dE^2)$  is invariant. In the C.M. frame this value is  $-dU^2$ , where  $dU$  is the gain in the internal energy, provided the system remains at rest in this frame. Hence

$$c^2 dP^2 - dE^2 < 0$$

If this inequality is satisfied the sign of  $dE$  cannot be reversed by a Lorentz transformation.

In Williams's examples the systems do not remain at rest in their respective C.M. frames.

## MOLECULAR STRUCTURE

### Calculation of Crystal Packing: A Novel Approach to the Phase Problem

THE structure and relative stability of helical macromolecules, consisting of repetitions of equivalent monomer units, have been analysed previously<sup>1-5</sup>. The conformational potential energy of the helices was computed as a function of the angles of rotation about the skeleton bonds, using semi-empirical potential functions to take into account intramolecular Van der Waals interactions between "non-bonded" atom pairs. The geometry of the most stable helices was deduced from the parameters corresponding to the lowest minima. It was also shown<sup>6</sup> that the crystal packing of hexamethylbenzene molecules may be predicted by locating the deepest minima of the intermolecular Van der Waals potential energy. By fixing bond lengths and angles and by knowing lattice parameters and crystal symmetries, the potential energy can be calculated for all the rotational and translational degrees of freedom which define the asymmetric unit position.

Equivalent methods, based on the analysis of intermolecular distances in molecular crystals, have been reported by Williams<sup>7,8</sup> and Rabinovich and Schmidt<sup>9</sup>. We are trying to apply this idea to the solution of the phase problem in molecular crystals when the molecular geometry is known, and have analysed the crystal structure of 5 $\alpha$ -androstane-3,17-dione (ANDR). The crystal structure of ANDR is unknown. We found the unit cell parameters of a single crystal, crystallized from normal hexane, to be in good agreement with those reported by Ohrt, Haner and Norton<sup>10</sup>, namely

$$a = 12.704 \text{ \AA}; b = 6.168 \text{ \AA}; c = 21.337 \text{ \AA}; \beta = 91^\circ 16'$$

The space group is C2, monoclinic non-centrosymmetric, with four molecules in general positions at  $x, y, z$ ;  $\bar{x}, y, \bar{z}$ ;  $\frac{1}{2} + x, \frac{1}{2} + y, z$ ;  $\frac{1}{2} - x, \frac{1}{2} + y, \bar{z}$ . Because the  $y$  co-ordinate can be fixed at zero for space group reasons, the translational

degrees of freedom are reduced to two. The experimental density,  $1.14 \text{ g cm}^{-3}$ , determined by flotation method, agrees with the calculated one,  $1.14 \text{ g cm}^{-3}$ , on the basis of four ANDR molecules per unit cell.

The conformation of ANDR was derived using bond lengths C—C =  $1.54 \text{ \AA}$ ; C—H =  $1.08 \text{ \AA}$  and C=O =  $1.23 \text{ \AA}$  and tetrahedral bond angles except for the following

$$\begin{aligned} \text{C}_2\text{C}_3\text{O}_{20} = \text{C}_4\text{C}_5\text{O}_{20} &= 125^\circ, \text{C}_{13}\text{C}_{17}\text{O}_{21} = \text{C}_{16}\text{C}_{17}\text{O}_{21} = 128^\circ, \\ \text{C}_{13}\text{C}_{17}\text{C}_{16} = \text{C}_{16}\text{C}_{15}\text{C}_{14} &= 104^\circ, \text{C}_{17}\text{C}_{16}\text{C}_{15} = 105^\circ \end{aligned}$$

and

$$\text{C}_{17}\text{C}_{13}\text{C}_{14} = \text{C}_{13}\text{C}_{14}\text{C}_{15} = 100^\circ$$

(see Fig. 1 for the atomic numbering).

The potential energy of a set of fourteen molecules in contact with the central one was calculated as a function of three rotational ( $\psi_1, \psi_2, \psi_3$ ) and two translational ( $t_x, t_z$ ) degrees of freedom, by adding the separate terms corresponding to "non bonded" pair interactions between carbon, oxygen and methyl groups. In a preliminary calculation the semi-empirical potential functions used previously<sup>2,3</sup> were adopted and the calculations were performed by means of a programme written for an IBM 7040 computer. To save computing time, angular and translational increments of  $20^\circ$  and  $1 \text{ \AA}$  respectively were used in the first run, neglecting contributions to the potential energy when the intermolecular distances were greater than  $5.5 \text{ \AA}$ . Broad regions of minima of the potential energy were analysed by means of a second run with angular and translational increments of  $10^\circ$  and  $0.5 \text{ \AA}$  respectively, including also the hydrogen atoms. All but nine minima were discarded because of some short intermolecular approaches.

All these nine minima were tested by calculating the reliability factor  $R$  for the ANDR  $h0l$  and  $0kl$  observed reflexions, which number 89 and 62 respectively, by allowing small systematic translations and rotations of ANDR molecules in the regions of the minima. Seven minima gave unsatisfactory  $R$  values, usually much greater than 0.70, and only the two deepest were considered promising. These minima have the same Eulerian angles<sup>6</sup> and translational parameters except for the  $\psi_3$  angles, which differ by  $170^\circ$  of rotation about the axis shown in Fig. 1. Moreover, most of the atoms coincide in the  $h0l$  projection, while in the  $0kl$  projection the differences are more marked.

A successive rigid body refinement by means of structure factors and Fourier synthesis calculations showed that the higher minimum should be rejected. The lower one gave the following agreement indices

$$R_{h0l} = 0.38; R_{0kl} = 0.35$$

with a mean isotropic temperature coefficient of  $3.5 \text{ \AA}$  (ref. 2). The parameters corresponding to the best  $R$  values are

$\psi_1 = -6^\circ$ ;  $\psi_2 = 343^\circ$ ;  $\psi_3 = 191^\circ$ ;  $t_x = 2.80 \text{ \AA}$ ;  $t_z = 5.21 \text{ \AA}$  and differ from those found by the potential energy analysis by

$$\begin{aligned} \Delta\psi_1 &= -4^\circ; \Delta\psi_2 = -3^\circ; \Delta\psi_3 = -1^\circ; \Delta t_x = 0.40 \text{ \AA}; \\ \Delta t_z &= 0.09 \text{ \AA} \end{aligned}$$

O21	0.1560	0.3546	0.4508

The relevant displacement along the  $x$  axis with respect to the position of the minimum brings O<sub>20</sub> into short contact with C<sub>2</sub> of the centrosymmetrical molecule and O<sub>21</sub> with C<sub>16</sub> of the molecule related by the diad axis.

The final atomic fractional co-ordinates are listed in Table 1 and the corresponding  $h0l$  and  $0kl$  electron density projections are reported in Figs. 2 and 3. Although the  $R$  values are rather high, we feel that they are adequate in view of the complexity of the structure. Fig. 4 shows the arrangement of the molecules in the crystal.

The  $h0l$  Fourier synthesis shows a low electron density of some peripheral atoms, probably due to a thermal anisotropy which is visible in the map. This effect appears to be strong and in the same direction as in the crystal structure of the parent compound 5 $\alpha$ -androstane-3 $\alpha$ -ol-17-one (ref. 11), in which the rigid body libration of the whole molecule has the largest component normal to a plane through the ring system. Moreover, the corresponding Fourier, performed with calculated diffraction amplitudes, indicates the existence of series-termination effects, which can be ascribed to the lack of  $h0l$

reflexions with  $2 \sin \theta > 1.5$ . On the other hand, the absence of spurious peaks in the Fourier syntheses, together with the good qualitative agreement between  $F_{\text{obs}}$  and  $F_{\text{calc}}$ , indicate that the structure is substantially correct. Better agreement could hardly be expected in view of the errors inherent in the molecular model of the pentacyclic ring structure. Three-dimensional data are being collected to refine both the molecular packing and the geometry.

## Reconstitution of Elastin

PARTRIDGE *et al.*<sup>1</sup> observed that hydrolysis of pure insoluble elastin from bovine ligamentum nuchae by oxalic acid gave rise to soluble elastin consisting of two fractions:  $\alpha$ -elastin with a mean molecular weight of 60,000–84,000; and  $\beta$ -elastin with a mean molecular weight of 5,000. Solutions of  $\alpha$ -elastin formed a reversible coacervate phase on heating. Hall and Czerkawski<sup>2</sup> showed that coacervation could be affected by detergents. On prolonged heating of the solutions of soluble elastin, a reconstituted product was prepared with characteristics similar in many respects to those of the original elastin<sup>3</sup>.

The reconstitution of elastin involves two steps<sup>4</sup>—the unfolding of polypeptidic chains and aggregation.

We investigated the possibility of reconstituting soluble proteins prepared by alkaline and acid hydrolysis of pure elastin from bovine ligamentum nuchae. Elastin isolated by the method of Partridge *et al.*<sup>1</sup> was either dispersed in 0.5 normal sodium hydroxide, kept at room temperature and, after the dissolution was complete, the solution dialysed against water to neutrality and lyophilized; or dissolved in hot 0.25 molar oxalic acid, dialysed against water and lyophilized.

We found that hydrolysed elastin could be precipitated in an elastic gel like sediment by heparin or heparinoids under suitable conditions.

The precipitation takes place in a very narrow range of pH, ionic strength and heparin (or heparinoid) concentration as shown in Table 1. The results were obtained with a synthetic heparinoid (disulphate ester of a high molecular fraction of starch).

Precipitation could also be achieved by dialysis of solutions containing soluble elastin and heparinoid in an appropriate ratio against 0.2 molar acetic acid.

We also tried to prepare similar products using detergents in place of heparin, but elastic gels did not form under the conditions of maximum coacervation of acidic hydrolysed elastin quoted by Hall and Czerkawski<sup>2</sup>. Changing the conditions, however, resulted in precipitation with anionic detergents (dodecylsulphate) or detergents containing both cationic and anionic groups, for example, 'Empigen OB'. Precipitation did not occur when cationic detergents were used.

Elastic gel like precipitates were also prepared by the addition of hydrochloric acid to solutions containing soluble elastin and dodecylsulphate or 'Empigen OB'. The concentration of detergent was 5 mg/ml., the final concentration of the acid was 0.1 molar. Precipitates also occurred by dialysis of solutions containing soluble elastin and detergent with acetic acid as described earlier. The products obtained were similar to those prepared with heparinoid.

The amino-acid compositions of the original elastin and the precipitated products are given in Table 2. Amino-acid analysis was carried out by the method of Spackman *et al.*<sup>5</sup>.

It is obvious that only slight differences exist between elastin and the product precipitated by heparinoid. The product prepared by precipitation with the detergent shows considerable differences in the content of glycine, valine, alanine and proline.

The precipitation by heparin involves all protein fractions in the solution; consequently even  $\beta$ -elastin must undergo this type of precipitation although it is not reconstituted by the method of Wood<sup>3</sup>. On the other hand, the precipitation by detergents is incomplete.

The fraction not precipitated is rich in those amino-acids in which the precipitate is poor. This contradicts

Table 2. AMINO-ACID COMPOSITION OF ELASTIN AND OF THE PRECIPITATED PREPARATIONS

	Elastin from ligamentum nuchae	Elastin reconstituted by heparinoid	Elastin reconstituted by dodecylsulphate

Values given as g/100g of protein.

the results given by Partridge *et al.*<sup>1</sup> and some other authors<sup>6</sup>, who found no differences in the amino-acid composition of  $\alpha$ -elastin and  $\beta$ -elastin. On the other hand, Gotte *et al.*<sup>7</sup> found that an interfibrillar protein fraction could be extracted from elastin prepared by the Partridge method, and that the composition of this fraction differed from the composition of fibrillar elastin. This might account for the different composition of the protein fractions precipitated and not precipitated by detergents.

Taking into consideration the narrow limits of pH and ionic strength in which elastic gel like sediments are formed, the results reported here support the theory that ionic interaction is involved in the reconstitution of elastin. The fact that the precipitation takes place at low values of pH suggests that an interaction occurs between strong acidic groups of the electrolyte and basic groups of polypeptides, and that the dissociation of weak acidic groups of polypeptides is suppressed.

The interaction between elastin and acidic polysaccharides may also be of importance for elastin fibrogenesis in view of the presence of acidic polysaccharides in ground substance. The fact that in identical conditions of pH and ionic strength the formation of the precipitate depends on the protein to polysaccharide ratio suggests that acidic polysaccharides contribute to the stability of elastin structure.

I thank Dr Roubal of the Research Institute of Pharmacy and Biochemistry, Prague, for providing samples of synthetic heparinoid, and the Czechoslovak Academy of Sciences for the amino-acid analysis.

Solutions in Britton-Robinson buffer, pH = 1.80; ionic strength 0.05 for the alkaline hydrolysate and 0.2 for the acidic hydrolysate.

## CHEMISTRY

### Energy Transfer from Chemiluminescent Species in Polymers

PREVIOUS work<sup>1</sup> has shown that in polymers when initiators decompose into primary free radicals chemiluminescence is produced in the visible region of the spectrum. When dicyclohexylperoxy-dicarbonate (P.C.) decomposes in polycarbonate, polystyrene and polymethyl methacrylate two maxima in the chemiluminescence spectra are observed at  $\lambda = 4500 \text{ \AA}$  and  $\lambda = 5300 \text{ \AA}$ , each apparently arising from a different elementary reaction. The short-wave-

Fig. 1. Kinetics of decay of chemiluminescence. I, Rubrene (5520); II, 9,10-dibromoanthracene (4400); III, rhodamine B (5800); IV, rhodamine 6G (5800); V, 1-5 diphenyl (3 para diphenyl) pyrazoline (4580); VI, phosphine 3R (4950); VII, quinine bisulphate (4700); VIII, naphthalene (4900); IX, pyronine Y (5600); X, pyronine G (5600). Figures in brackets show wavelength in Å of emission maxima.

length chemiluminescence probably results from cage disproportionation of radicals from the initiator

giving an electronically excited cyclohexanone molecule in its triplet state. The nature of the elementary reaction giving rise to the long-wave chemiluminescence is as yet unknown.

The present work is a study of energy transfer from the chemiluminescent species to different energy acceptors introduced into the polymers. The energy transfer was studied spectroscopically, and, in general, in the presence of a large enough concentration of acceptor a new chemiluminescence spectrum is observed which coincides with the photoluminescence spectrum of the acceptor. The effectiveness of energy transfer to different acceptors is summarized in Table 1.

The first group of molecules in Table 1 accept the energy effectively from the excited cyclohexanone molecule. Thus in the presence of 9,10-dibromoanthracene the emission due to cyclohexanone disappears and the characteristic spectrum of 9,10-dibromoanthracene appears. The long-

wavelength chemiluminescence at  $\lambda = 5300 \text{ Å}$  is, however, unaffected by the presence of the 9,10-dibromoanthracene.

The acceptors in the second group in Table 1 may also accept energy effectively from the chemiluminescent species, because the characteristic spectra of these molecules are also observed. They are, however, distinguished from the first group (labelled "good" in Table 1) because the kinetics of chemiluminescence decay are different. As was shown previously<sup>1</sup>, during the decomposition of the initiator in the absence of an acceptor, the intensity of the short-wave chemiluminescence decays exponentially, and the rate constant for the decay is identical to the first order rate constant for the decomposition of the initiator. Under these conditions the decay of the long-wave chemiluminescence is much more rapid than that of the short-wavelength. With the first group of energy acceptors in Table 1, the intensity of the chemiluminescence arising by energy transfer was also observed to decay exponentially, and with a rate constant identical to that of the rate constant for the decomposition of the initiator. The emission, however, from the second group of acceptors was observed to decrease more rapidly than that of the short-wave luminescence or the "good" acceptors. This is seen in Fig. 1 where the kinetics of the decay of these acceptors are compared with those of 9,10-dibromoanthracene. The rapid decrease may result from energy transfer from species giving rise to the long-wavelength emission, or may be due to a chemical excitation of the acceptor by another reaction, for example, a direct reaction between acceptor and peroxy-initiator. Energy transfer to the third group of molecules in Table 1 could not be observed spectroscopically.

A comparison of the spectra of photo- and chemiluminescence indicates that energy transfer produces the fluorescent states of 9,10-dibromoanthracene and rhodamine 6G and the phosphorescent states of naphthalene, diacetyl and benzil.

Fig. 2. A, Increase in luminescence with increase of concentration of acceptor in polycarbonate: ●, rhodamine 6G; ×, 9,10-dibromoanthracene; ○, benzil. B, Data from A fitted to equation (1).

Table 1. EFFECTIVENESS OF ENERGY TRANSFER FOR DIFFERENT ACCEPTORS

	Molecule	Concentration moles/l. $\times 10^2$	Intensity quanta/decomp. $\times 10^2$	Class

## MATHEMATICS—NEW AND RECENT TITLES

### Wave Propagation and Turbulent Media. R. A. Adams and E. D. Denman

R. N. Adams, *University of Kentucky*; and E. D. Denman, *Vanderbilt University, U.S.A.*

Contents: Preface; introduction; wave propagation in inhomogeneous medium; derivation of the recurrence equations using signal flow graphs; solution to the Epstein variation; turbulent medium; results and accuracy; conclusions; references; appendices; index. 65s.

### The Remarkable Sine Functions. A. I. Markushevich

*Moscow State University, U.S.S.R.*

Contents: Preface; geometric definition of circular, hyperbolic and lemniscate functions; generalized sines; integration in the complex plane; Euler's method of deriving the addition theorems; further study of complex values of the argument; zeros and poles; simple and double periodicity—the concept of an elliptic function; index. 55s.

### Entire Functions. A. I. Markushevich

*Moscow State University, U.S.S.R.*

Contents: Preface; the concept of an entire function; the maximum absolute value and the order of an entire function; the zeros of an entire function; the fundamental theorem of algebra and Picard's little theorem; algebraic relationships and addition theorems; appendix; index. 55s.

### Numerical Inversion of the Laplace Transform.

R. Bellman, R. E. Kalaba and J. A. Lockett

Richard Bellman, *University of Southern California*; Robert E. Kalaba and Jo Ann Lockett, *The RAND Corporation*

Contents: Introduction; elementary properties of the laplace transform; numerical inversion of the laplace transform; linear functional equations; nonlinear equations; dynamic programming and ill-conditioned systems; appendices; index. 80s.

### Approximations of Functions. Edited by H. L. Garabedian

*General Motors Research Laboratories, Warren, Michigan, U.S.A.*

Contents: Preface; the convergence of sequences of rational functions of best approximation with some free poles; uses of Hilbert space in approximation; applications of duality in approximation theory; inclusion theorems for the minimal distance in rational Tschebyscheff approximation with several variables; rational approximation on finite point sets; phase methods for polynomial approximation; approximation by generalized rational functions; nonlinear approximation; nonlinear sequence transformations; approximation theory in the first two decades of electronic computers; piecewise polynomial interpolation and approximation; Russian literature on approximation in 1958–1964. Index. 80s.

### The Language of Logic. Hans Freudenthal

*Professor of Pure and Applied Mathematics, Utrecht University, Utrecht, The Netherlands*

Contents: Sets and mappings; propositions; subject and predicate; formal logic; language and meta-language; solutions. 30s.

### Readings in Automatic Language Processing. Edited by David G. Hays

*The RAND Corporation*

Contents: Preface; introduction; specification languages for mechanical languages and their processors; natural language in computer form; a high-speed large-capacity dictionary system; parsing; the predictive analyser; connectability calculations, syntactic functions, and Russian syntax; the grammar of specifiers; research methodology for machine translation; on the mechanization of syntactic analysis; keyword-in-context index for technical literature; automatic phrase matching; a framework for syntactic translation; index. 80s.

## Theory of Chemical Pathology Technique

### A Guide for Medical Laboratory Technologists

By Ronald A. McAllister, FIMLT, MIBiol.

This comprehensive introduction to an important subject in any laboratory technologist's training, which is supplemented by numerous references, a thorough index and questions based on the text, will serve the student throughout his studies.

181 pages illustrated 38s.

## Ultra-Violet and Visible Spectroscopy:

### Chemical Applications

Second Edition

By C. N. R. Rao, DSc, PhD, FRIC, FASc.

For the second edition of this widely acclaimed book, extensive revisions have been made throughout and a new chapter on the absorption spectra of molecules of biological interest has been added.

223 pages illustrated 50s.

## Principles of Gas Lasers

By L. Allen, BSc, PhD, ARCS, DIC and D. G. C. Jones, BSc, PhD.

An account of gas lasers suitable for the graduate physicist and the third year undergraduate. It discusses the laser, the theory of resonant optical cavities, the interaction of radiation with matter and the analysis of population inversion and excitation mechanisms in existing gaseous lasers. Types of gas lasers are then considered and coherence is defined and discussed. A survey of the many applications of lasers completes the book.

167 pages illustrated 48s.

## Scientiae Pharmaceuticae

Edited by Dr Oldrich Hanc and Dr Josef Hubik

This two-volume work which contains 180 papers from international contributors records the Proceedings of the 25th Congress of Pharmaceutical Sciences held in Prague, 24-27th August 1965. Published by Butterworths in association with the Czechoslovak Medical Press.

In two volumes 1,157 pages illustrated £10 15s.

## INTERSCIENCE

### MECHANISMS OF INORGANIC REACTIONS: A Study of Metal Complexes in Solution, Second Edition

by FRED BASOLO, *Northwestern University*, and  
RALPH C. PEARSON, *Northwestern University*.

A book on modern inorganic chemistry with emphasis on chemical reactions rather than structure. Uses molecular orbital theory wherever possible. Now includes a chapter on reactions of the transition metal organometallics, and many results obtained as a result of the recent proliferation of rapid reaction techniques.

701 pages 144s.

### APPLICATIONS OF APPLIED STATISTICS, Volumes 1 & 2

by I. M. CHAKRAVARTI, *University of North Carolina*, R. G. LAHA, *The Catholic University of America*, and J. ROY, *The Pennsylvania State University*.

A clear exposition of basic statistical methods, illustrated by worked-out examples and many exercises drawn from various fields of application. The four parts cover: Techniques of Computation; Descriptive Methods; Statistical Inference; Planning of Surveys and Experiments. Vol. 1: 460 pages 98s.

Vol. 2: 160 pages 68s.

### SYSTEMS ENGINEERING METHODS

by HAROLD CHESTNUT, *General Electric Company*.

Discusses the importance of a broad systems approach to improve decision-making capability. Develops each systems problem under study in its entirety, from the initial system definition phase through to the operating and phase-out periods. Although oriented to engineering systems, seeks a formalized design to solve various systems development problems. (A volume in the Systems Engineering and Analysis series.) 392 pages 96s. Due September, 1967.

### ADVANCES IN ELECTROCHEMISTRY AND ELECTROCHEMICAL ENGINEERING, Volume 6

Editors: PAUL DELAHAY, *New York University*, and CHARLES W. TOBIAS, *University of California, Berkeley*.

This volume begins with an authoritative analysis of some aspects of the electrical double layer and concludes with a discussion of the novel field of organic semiconductor electrodes.

482 pages 155s. Due October, 1967

### HETEROCYCLIC COMPOUNDS, Volume 9

edited by ROBERT C. ELDERFIELD, *University of Michigan*.

The latest volume in a series that discusses the chemical principles underlying the syntheses and reactions of heterocyclic compounds. 462 pages 225s.

# A faultless sequence

## automatically

With the Carl Zeiss Photomicroscope, you can concentrate on the specimen—instead of camera work. That's done automatically by the built-in photographic system. The touch of a button selects the right exposure time, opens and closes the shutter, advances the film, actuates a film counter and re-cocks the shutter. Result: faultless sequences in color or black-and-white. □ This truly universal microscope gives you all the practical versatility you have come to expect of a Zeiss microscope. It can be equipped for transmitted or reflected illumination. There are also various exchangeable stages and optics for bright-field, dark-field, phase-contrast, polarization and transmitted-light interference work. □ The instrument has a built-in, pre-centered 6-volt lamp. But you can also use a 12-volt lamp or high-pressure mercury burner for ultra-violet or fluorescence microscopy. □ The built-in Zeiss OPTOVAR provides three different magnifications for each eyepiece/objective combination—without changing focus. □ Full details from sole

### An Introduction to the Statistical Theory of Classical Simple Dense Fluids

G. H. A. COLE, *Professor of Theoretical Physics, The University, Hull*

The emphasis throughout the book is on simplicity of mathematical argument and a wide range of comments and references is included to allow the reader to extend and follow up the arguments developed in the text.

*Chapter Headings:* Empirical considerations; Microscopic representation; Fluid statistical thermodynamics; Theory of equilibrium short-range order; Theory of equilibrium short-range order; Total correlation; Some numerical consequences of the equilibrium theory; Irreversibility; Non-equilibrium gases; Non-equilibrium liquids; References; Comments; Index.

296 pages/75s./\$12.00

### Molecular Complexes

J. ROSE, *Blackburn College of Technology and Design*

*Chapter Headings:* Introduction; Bonding and energetics of bond formation in molecular complexes; Compositions and stabilities of molecular complexes; Properties of molecular complexes; Effects of structures of donors and acceptors on complex formation; Molecular complexes of group III of the periodic table; Applications of molecular complexes.

184 pages/50s./\$8.00

### Extrusion Reactions

B. P. STARK, *Chief Research Chemist, CIBA (A.R.L.) Ltd., Duxford, Cambridge and*

A. H. DUKE, *Head of Coatings Department, Richard Thomas and Baldwins Ltd., Aylesbury*

*Partial Contents:* Extrusions and their classification; Extrusions from bridged carbonyl compounds; Other extrusions of carbon monoxide or carbon dioxide; Extrusions of sulphur dioxide and other oxidized sulphur fragments; Extrusions of the elementary chalcogens; Extrusion of nitrogen from pyrazolines and 3H-Pyrazoles; Extrusion of nitrogen from triazolines; Possible intervention of oxadiazolines and thiadiazolines in syntheses of Oxirans and thirans; Other extrusions of nitrogen; Extrusion of other inorganic fragments; Multiple extrusions; Inter-relations and conclusions.

200 pages/63s./\$10.00

### Flight Test Instrumentation, Volume 4

M. A. PERRY, *Department of Flight, College of Aeronautics, Cranfield, Bedfordshire*

This volume contains a selection of the papers presented at the 4th International Aerospace Instrumentation Symposium held at Cranfield, March 1966. The Symposium, previously known as Flight Test Instrumentation, recognized the need to take notice of the increasing importance of experiments in space, hence its new title. This series will appeal to workers and students in the fields of Aeronautical and Instrument Engineering as well as to Aerospace Industries.

*Cranfield Symposium Series, Volume 9*

292 pages/£5 5s./\$16.00

### Electromagnetic Wave Theory—In two parts

Proceedings of a Symposium held in Delft, Netherlands, September 1965

Edited by J. BROWN, *University College, London*

The contributions by specialists from many countries summarize the latest developments in the branches of electromagnetic wave theory relevant to radio wave propagation and the design of antennae. Of outstanding interest is a survey of lateral waves by Felsen. The section on scattering and diffraction provides a clear, comprehensive account of the state of the subject; among other topics of current interest, is an excellent review of diffraction theory.

*International Series of Monographs on Electromagnetic Waves*

Sold as a two-part set

Part One: 562 pages/£7/\$21.50

Part Two: 558 pages/£7/\$21.50

### Inorganic and Nuclear Chemistry Letters

*An  
International  
Journal*

Editor: JOSEPH J. KATZ

This is an international journal providing a means of rapid communication in the broad areas of inorganic and nuclear chemistry. Papers are in English, French and German, and concern synthetic and structural inorganic chemistry, co-ordination chemistry, kinetics and mechanism of inorganic reactions, nuclear properties and reactions.

Published Monthly

Table 2. DISTANCE FOR EFFECTIVE ENERGY TRANSFER

Acceptor	$V \text{ \AA}^3$	$r \text{ \AA}^3$
Benzil	42,000	10
9,10-Dibromoanthracene	30,000	19
Rhodamine 6G*	75,000	26

\* Assumes that excited rhodamine 6G molecules originate only by energy transfer from cyclohexanone.

To measure the distance across which energy transfer could occur, a study of the intensity of activated chemiluminescence as a function of concentration of three acceptors, 9,10-dibromoanthracene, benzil and rhodamine 6G, was undertaken. The data fit a modification of the Perrin equation<sup>2</sup> (Fig. 2) which we use to describe the concentration dependence.

$$\frac{I_A}{I_{A\infty}} = 1 - e^{-Vn} \quad (1)$$

where  $I_A$  and  $I_{A\infty}$  are the intensity and limiting intensity of activated chemiluminescence respectively,  $n$  is the concentration of acceptor in molecules/unit volume and  $V$  is the volume of sphere inside which energy transfer occurs. The volumes of the spheres and distances  $r$  between interacting donor and acceptor molecules on this basis are shown in Table 2.

The values obtained for benzil are in good agreement with the values obtained by Ermolaev<sup>3</sup> for triplet-triplet energy transfer between different donors and acceptors. As predicted by theory<sup>4</sup>, the triplet-singlet transfer is seen to occur at greater distances.

### Electroactive Species produced by Electrolysis at Mercury Cathodes in Aqueous Solution

THERE is evidence that in electrolysis of aqueous solutions at mercury cathodes the accumulation of atomic hydrogen dissolved in mercury as an amalgam, as suggested by Heyrovsky<sup>1</sup> and Ilkovic<sup>2</sup>. Müller<sup>3</sup> re-investigated hydronium ion discharge at dropping mercury electrodes, and attributed long term changes in volume to a slow step in the overall reaction

either elimination of hydrogen from an amalgam, or decomposition of aqueous hydrogen molecule ions. The present work confirms that hysteresis is associated with the metal phase. We also present evidence for the occurrence of electrochemical desorption

at mercury containing dissolved hydrogen atoms.

Cathodes of triply distilled mercury (Shawinigan C.P.) were polarized with respect to a 0.1 molar potassium chloride calomel reference electrode by means of a bright platinum anode, separated from the cathode by a long, narrow tube. Anaerobic conditions were maintained by use of high purity hydrogen and mercury seals. Reagent grade potassium chloride,  $\text{Na}_2\text{HPO}_4 \cdot 7\text{H}_2\text{O}$  and  $\text{NaH}_2\text{PO}_4$ .

$\text{H}_2\text{O}$  were dissolved in distilled deionized water to make 0.1 molar potassium chloride buffered<sup>4</sup> to pH 7.5. Potentiostatic and triangular voltage measurements were made using an 'Exact 301' function generator, feeding into a 'Heath EUW 401' polarography system. Current-potential curves were recorded on a Houston Instruments 'HR98-T' X-Y recorder. A Keithley 662 differential voltmeter was used to measure potentials.

During extended cathodization at constant potentials of -1.0 to -1.5 V in hydrogen stirred solution, the cathodic current declined continuously. Subsequent open circuit decays were slow, taking several hours to reach a potential near the reference value, and current-voltage curves (Fig. 1) using a triangular sweep were considerably modified. The development of peaks in the anodic and cathodic half-cycles at -1.05 V and -1.2 V respectively was the most striking change. The effects were completely, though slowly, reversible.

The current rise at -1.3 to -1.4 V (A2, 16) is evidently caused by an essentially "irreversible" cathodic process, for the cathodic area, initially larger than the anodic, became progressively smaller (compare A15, 16 with A1, 2) because of an enhanced anodic faradaic current component. This was undoubtedly caused by the accumulation of a product of cathodization, the oxidation of which led to the balancing out of the capacitive currents at > -1.0 V, the appearance of the anodic peak at -1.05 V and the increase of the anodic area to three times the cathodic area (Fig. 1, B5), after 40 h at -1.3 V (net cathodic current falling from about 1 to 0.1  $\mu\text{amp cm}^{-2}$ ). At the same time the cathodic current at -1.4 V was suppressed, along with growth of a cathodic peak, barely noticeable in A2 and A16, at -1.2 V.

The parallel growth and decay of the anodic and cathodic peaks, at -1.05 V and at -1.2 V, respectively, suggest a common origin. The evidence suggests that the anodic peak is caused by hydrogen ionization

and the cathodic peak by electrochemical desorption (1). The more positive potential of the latter, relative to hydronium ion discharge, is consistent with the easier occurrence of (1) on metals such as mercury which adsorb hydrogen only weakly<sup>5</sup>.

Fig. 1. Current-voltage curves in triangular voltage cycles at 0.1 c/s with continuous stirring by hydrogen before (curves A) and after (curves B) cathodization for 40 h at -1.3 V. Cycles A1 to A16 and B1 to B11, respectively, were consecutive without interruption. Extreme curves only illustrated, except B1, for which peaks were greater than B5. Electrode area about 2 cm<sup>2</sup>. Anodic currents are positive.

The rates of both (1) and (2) will increase with hydrogen atom coverage, while that of hydronium ion discharge is expected to decrease. During cathodization, in the absence of a recombination catalyst, the hydrogen atom coverage, initially very low<sup>6</sup>, will gradually rise, keeping pace with the bulk concentration of hydrogen atoms. Thus the rates of (1) and (2) will gradually rise, as observed.

The absence of a stirring effect on the curves of Fig. 1 is consistent with rate limitation by hydrogen atom diffusion in the metal, while the observation of a bubble of hydrogen around the platinum contact wire and below the mercury, when electrolysis was continued for about 1 week, is evidence that hydrogen can accumulate in mercury. No bubbles were observed in the shorter experiment of Fig. 1; in this the charge passed was equivalent to only 1.5  $\mu\text{g}$  of hydrogen, a quantity that would be difficult to see.

The possibility of an impurity effect is unlikely, for no important impurity was detected polarographically. Furthermore, the suppression of the cathodic current at  $-1.4$  V, along with the growth of a new cathodic peak, is difficult to explain on such a basis. An effect on the triangular voltage curves was apparent even after a very small number of sweeps and persisted for a great many sweeps after prolonged cathodization.

Equally, discharge of alkali ions at  $-1.3$  V can be discounted, the discharge potentials being considerably more negative. The potassium ion discharge current at  $-1.3$  V has been estimated from residual currents in deoxygenated potassium chloride at  $-1.9$  to  $-2.0$  V, assuming a Tafel

slope of  $\frac{2RT}{F}$  to be  $\sim 10^{-11}$  amp  $\text{cm}^{-2}$ , that is quite negli-

gible (unpublished work of H. U. Heintze and F. R. Smith).

Although at  $10^{-7.5}$  molar the rate of discharge of bulk hydronium ions (extrapolation of Bagotskii and Yablokova's<sup>8</sup> data) is unlikely to exceed  $10^{-9}$  amp  $\text{cm}^{-2}$ , this will be supplemented by rapid water and phosphate ion dissociations, of which the former can support a diffusion current<sup>9</sup> of 5  $\mu\text{amp cm}^{-2}$ . This is adequate to account for the observations.

We thank the National Research Council of Canada for support.

## BIOLOGY

### Role of Carbon Dioxide in Erythropoiesis

THE use of gas mixtures containing 5 per cent carbon dioxide gas has become a standard procedure for the cultivation of cells *in vitro*. In some systems, however, a higher concentration has proved essential<sup>1,2</sup>. In bone marrow cultures different concentrations of carbon dioxide have been used<sup>3,4</sup>, but the interest has centred on the role of oxygen and little attention has been paid to the function of the other gases in the mixtures. In the

present system for the cultivation of rat bone marrow *in vitro* 30 per cent carbon dioxide (which is considerably higher than any concentration previously reported) has been found to stimulate erythropoiesis<sup>5</sup>. This effect has now been investigated in detail.

Cultures were prepared from the femoral bone marrow of Sprague-Dawley rats weighing 120 g as described previously<sup>5</sup>. The cells were grown on a coverslip, in a small Petri dish using 75, 80 or 100 per cent isogenic serum as nutrient. The remainder of the medium was synthetic medium *M* 150 (ref. 6). In these conditions most of the immature cells remained on the coverslip while most of the reticulocytes and erythrocytes were released into the supernatant fluid. The fluid was therefore somewhat analogous to the peripheral blood *in vivo* and was used for reticulocyte counts in the conventional manner<sup>7</sup>.

Initially the cultures contained very few non-nucleated cells<sup>8</sup>, but when they were maintained in 3, 15 or 30 per cent carbon dioxide in air it was found that the highest percentage produced a consistently higher reticulocyte count throughout the life span of the culture (Fig. 1). When the gas mixture was composed of 30 per cent carbon dioxide, 20 per cent oxygen and 50 per cent nitrogen, the same high reticulocyte count was obtained which shows that the effect was not due to the concomitant decrease in oxygen.

When cultures were started in 3 per cent carbon dioxide and moved to 30 per cent carbon dioxide after different intervals *in vitro*, a surge of reticulocyte production occurred within 24 h after moving (Fig. 2). In the young cultures, where the initial percentage of reticulocytes was high, the increase was consistent but not very large. In the older cultures, however, where the reticulocyte percentage was negligible in 3 per cent carbon dioxide, the response to 30 per cent carbon dioxide was highly significant.

The beneficial effect of 30 per cent carbon dioxide on the production of reticulocytes was not due to low pH alone. Cultures in this concentration of carbon dioxide had a pH between 6.0 and 6.4. When low concentrations of serum (5–50 per cent) were used, the same pH was reached but very few mature cells were produced. The optimum conditions therefore required both high serum and high carbon dioxide.

Thus it appears that a high concentration of carbon dioxide in the presence of some serum component(s) stimulates the erythropoietic system of the marrow *in vitro*. Because no kidney tissue is available for the

Fig. 1. The effect of continuous exposure to 3 (●—●), 15 (△—△), or 30 (○—○) per cent carbon dioxide in air on percentage of reticulocytes in the supernatant fluid.

Fig. 2. Changes in percentage of reticulocytes as a result of moving cultures from 3 per cent carbon dioxide (●) to 30 per cent carbon dioxide (○) after different intervals *in vitro*.

production of erythropoietin, this response is either independent of the hormone, or involves the activation of a latent form present in the serum. An activation of erythropoietin by divalent cations has recently been suggested<sup>8</sup>. On the other hand, divalent cations are known to stimulate mitosis in bone marrow<sup>9</sup>, and prolonged exposure to high carbon dioxide stimulates the uptake of calcium by erythrocytes<sup>10</sup>. If high concentrations of carbon dioxide have the same effect on the nucleated cells of the erythron, these results could be interpreted as follows: carbon dioxide stimulates the entry of calcium into the primitive cells of the marrow, and the calcium then stimulates these cells to divide and mature. Whether or not there is any connexion between this system and activation of an inactive serum erythropoietin requires further investigation.

I thank Miss M. Lenormand and Mr R. J. Isaacs for technical assistance.

## Strontium, Calcium and Magnesium in Brown Algae

THE ion exchange properties of alginates have received some attention lately, particularly because of their potential value in connexion with therapy after strontium-90 overdoses<sup>1-3</sup>. It has been shown that alginates rich in

Sea water <sup>7</sup> of chlorinity 19		0.0102	0.0536	0.000156

gularonic acid residues have a greater affinity for calcium in the ion exchange reaction calcium-magnesium<sup>4</sup> and for strontium in the ion exchange reaction strontium-calcium<sup>5</sup>.

The proportion of mannuronic and gularonic acid in the alginates varies from one species of brown algae to another<sup>6</sup>, and also in some cases from one type of tissue to another within a plant<sup>6</sup>. We have determined the content of calcium, magnesium and strontium in some samples of brown algae and of different parts of brown algae by extraction with 0.2 normal hydrochloric acid and analysis by means of atomic absorption. The results are given in Table 1 together with the uronic acid composition of the alginate present in the samples.

The results clearly indicate a correlation between the uronic acid composition of the alginates and the relative amounts of the three divalent metals in the plants.

If we consider the brown algae as ion exchange materials immersed in sea water, and if we assume that the different ion exchange reactions can be regarded independently of

Fig. 1. Selectivity coefficients of algal samples as a function of the uronic acid composition of the alginate.  $\times$ ,  $k_{Sr-Mg}^{Sr}$ ;  $\bullet$ ,  $k_{Sr-Ca}^{Sr}$ ; —, selectivity coefficients for alginate.

each other, we can calculate the selectivity coefficients for the ion exchange reactions strontium-calcium and strontium-magnesium from the results given in Table 1.

The selectivity coefficient is defined by the equation

$$k_{\text{MeI}}^{\text{MeII}} = \frac{[\text{MeI}]_a \cdot [\text{MeII}]_w}{[\text{MeII}]_a \cdot [\text{MeI}]_w}$$

where subscripts *a* and *w* refer to algae and sea water respectively and the figures within the brackets refer to the concentration of the ions. It has been shown<sup>8,9</sup> that the activity coefficients for calcium and magnesium ions in sea water are about equal, and, assuming the same activity coefficient also for strontium ions, the ratio between the ion concentrations should be approximately equal to the ratio between the activities of the ions.

In Fig. 1 the resulting selectivity coefficients are shown as a function of the uronic acid composition of the alginates. The curves represent the results obtained from laboratory experiments with pure alginates. The agreement between the results obtained for pure alginates in salt solutions and for brown algae living in their natural environment is remarkably good. A complete agreement should not be expected, because the experiments with alginates are carried out in conditions where approximately equal amounts of the two ions are bound to the polymer; and previous results have shown that the selectivity coefficients show some dependence on the ratio of the two cations bound to the alginate<sup>10</sup>. The results therefore indicate that the content of the divalent metals calcium, magnesium and strontium in brown algae to a large extent is determined by the ion exchange taking place between the sea water and the alginate in the plants.

### Side Effects of Dimethyl Sulphoxide

IN view of the increasing interest in the therapeutic value of dimethyl sulphoxide (DMSO) (refs. 1 and 2), we felt that the recent report by Barnett and Noel<sup>3</sup> called for some comment. The only important side effect so far reported in animal experiments has been an effect on the lens<sup>4,5</sup> and it is only as a result of these reports that widespread clinical use of DMSO has been delayed.

Both in the recent paper and the original report, the doses used were far in excess of any possible level which would be considered for clinical practice. Furthermore, the doses given to monkeys were administered by gastric intubation and no systemic use for humans is contemplated at the present time. The highest daily dermal dose so far reported in work with monkeys is 11 g/kg (ref. 6). This has been given for up to 6 months without affecting the lens. Extrapolating the reported data from monkey to man would mean that, in order to achieve even slight changes in the lens, a dose of 200 g/day would be required. At levels such as these the question of impurities becomes important and no mention of the type, source or purity of the product used in these experiments is given by the authors. This omission has been pointed out on

a previous occasion<sup>7</sup> and it is regrettable that this group should continue to overlook these basic data.

DMSO has now been used in quite extensive clinical trials for periods of up to 2 years with only one lens opacity being reported<sup>8</sup>, and in this case the author considered it to be unrelated to DMSO.

It is only because of the exceptionally low general toxicity of DMSO that such massive doses can be administered at all. Indeed, we wonder what other substance with such high physiological activity could be given in the same quantity without producing much more drastic changes in many tissues.

It is important that this ocular side effect should be seen in its proper perspective.

### Invasion of Wheat Roots by *Pratylenchus thornei*

SEINHORST developed a model to relate the density of nematodes in a population and the damage caused to plants<sup>1</sup>. Later he developed another model to relate the increase in the population and the density of the population<sup>2</sup>. These models, based on the relationships between predator and prey of Nicholson and Bailey<sup>3</sup>, make two principal assumptions: (a) the "average" nematode is the same at all densities; and (b) the nematodes invade the host tissue randomly, that is they do not attract or repel each other.

The percentage of larvae of *Ditylenchus dipsaci* that invaded oat seedlings declined as the number of larvae in the inoculum increased<sup>4</sup>. Similar observations were made for *Heterodera rostochiensis* on potato<sup>5</sup> and for *Meloidogyne incognita* on tomato<sup>6</sup>. Larvae of *M. incognita* have been observed directly to enter a root through a single wound made by the first larva to invade. Attraction of larvae was stronger<sup>7</sup>, and invasion more rapid<sup>8</sup>, after the root had been punctured by the first larva. Wallace<sup>6</sup> suggested six reasons why invasion could be dependent on density and considered that the supporting evidence cast doubt on the validity of Seinhorst's assumption.

Seinhorst<sup>2</sup> states that the "second assumption could be tested by observing the distribution of nematodes in or on the roots". We have done this for *Pratylenchus thornei* Sher and Allen in wheat roots and the results cast doubt on the validity of the second assumption. Wheat seedlings were established in sand and, when 4 weeks old, each was inoculated with either 1,500 or 6,000 *P. thornei*. Two weeks later, the roots were removed, immersed in Fleming's fixative to stain embedded nematodes<sup>9</sup>, fixed in chrom-acetic acid overnight, passed through a graded series of alcohols and finally cleared in cedar wood oil.

Fifty pieces of root each 20 mm long were selected at random from plants inoculated with 1,500 nematodes. Forty-two pieces contained no nematodes, and the other eight contained between one and fifty-three nematodes. Long pieces of root were then selected at random from those containing nematodes, and the number of nematodes in each millimetre was counted with an ocular micrometer (Fig. 1).

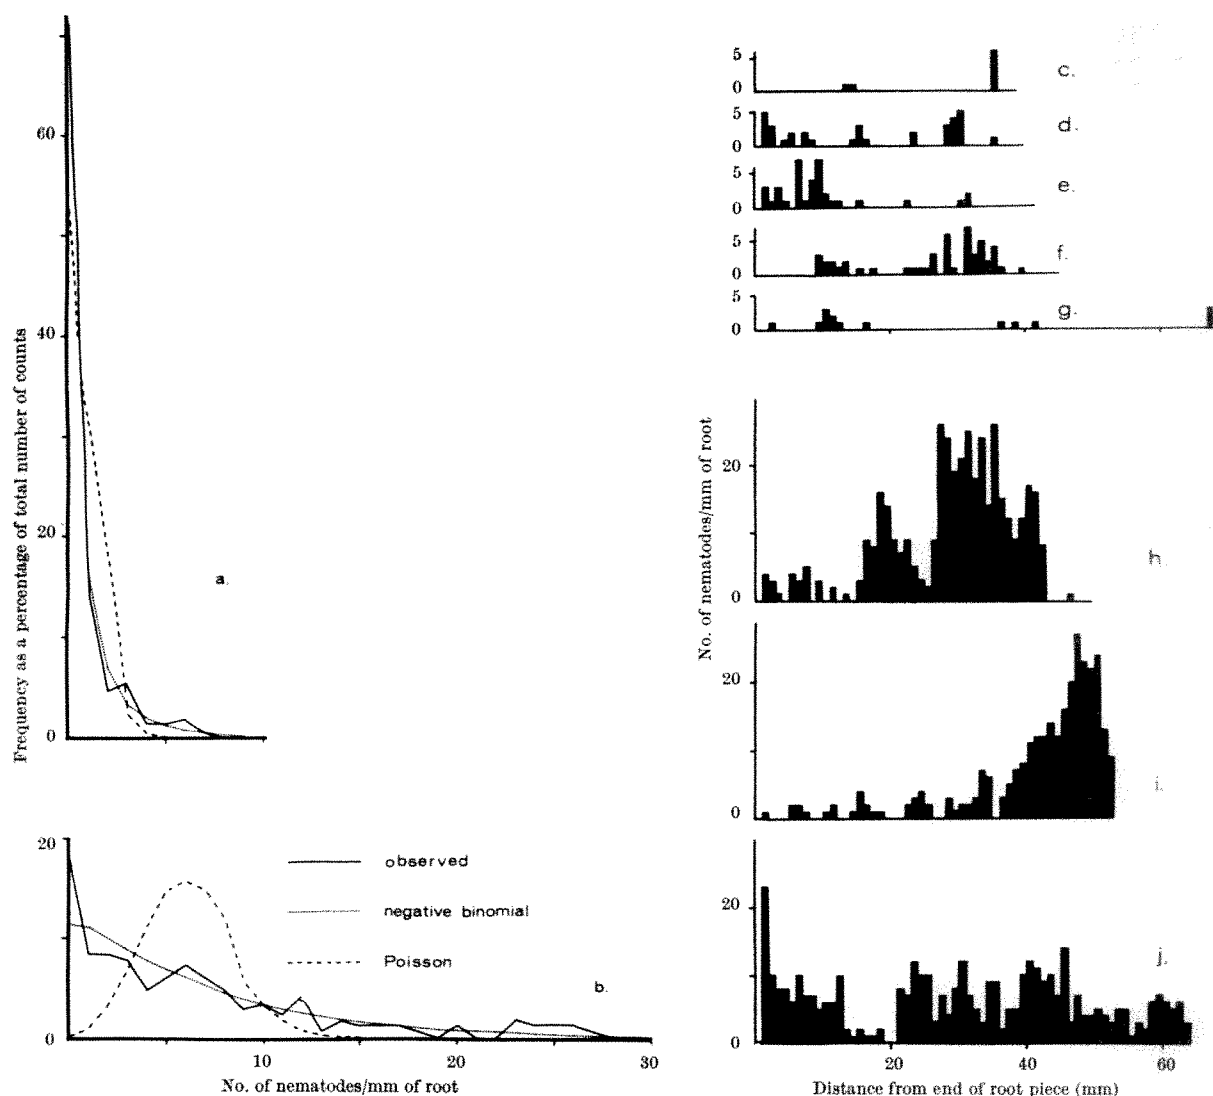

Fig. 1. The observed and calculated frequency distributions of *Pratylenchus thornei* in wheat roots of plants inoculated with (a) 1,500 and (b) 6,000 nematodes/plant. The number and distribution of *P. thornei* in lengths of wheat roots from plants inoculated with (c to g) 1,500 and (h to j) 6,000 nematodes/plant.

Because the seedlings had been inoculated for only 2 weeks the nematodes had not reproduced and, from other observations, had entered near their present site in the root. Of the roots examined, relatively few had been invaded. For the root pieces containing nematodes, if each millimetre had an equal chance of being invaded, then the observed distribution of nematodes in the root should follow a Poisson distribution. The values of  $\chi^2$  show that, for both levels of inoculum, the observed data did not fit a Poisson distribution but fitted a negative binomial distribution well (Table 1). This suggests that some parts of the root had a greater chance of being invaded than others.

Environmental differences along a root could favour invasion of some parts. The design of the experiment aimed to minimize such differences by establishing a constant temperature and moisture regime in the sand. Also, some parts of a root may have been more suitable for invasion, but no structural differences could be detected

and invasion was not constantly associated with any particular part of the root. An alternative explanation is that the initial invasion was random, but that other nematodes then entered through the wounds caused by the initial invaders. Cell contents may have escaped through such wounds and attracted other nematodes to that region of the root. These last two possibilities, both incompatible with the assumption that "nematodes act independently" during invasion, provide the most likely explanation of the localized regions of heavy invasion observed in wheat roots. These results are not unexpected because species of *Pratylenchus*<sup>9</sup> and other nematodes<sup>10</sup> orientate to chemical gradients.

### *Podocarpus* Root Nodules in Sterile Culture

THE morphology of the root nodules of *Podocarpus* has attracted more attention than that of any other non-leguminous plant, and the nodules have been regarded as a response to infection by bacteria<sup>1-4</sup> or by non-septate fungi<sup>5-10</sup>. The endophyte is considered not to be causal by recent workers<sup>11,12</sup>, but the nodules are thought to be arrested lateral roots with the cortex renewed annually. Attempts by Baylis *et al.*<sup>11</sup> to maintain *Podocarpus* seedlings in sterile culture long enough to permit nodule development were unsuccessful, although nodules were formed in cultures which proved to be entirely free from fungi. We have investigated the production of root nodules in sterile culture.

Shoot cuttings from *Podocarpus lawrencei* Hook., after surface sterilization, were planted in pots of autoclaved sand and peat (equal parts) in completely sterile conditions. The structures (Fig. 2b) of the nodules produced on the adventitious roots which arose from the cuttings were the same as those which have been described before, although in contrast to nodules on plants grown in the field (Fig. 2a) no endophyte could be seen. Staining of smears and sections for bacteria gave negative results. Malt-'Marmite' agar plates inoculated with crushed surface-sterilized nodules remained free of micro-organisms on incubation for 3 weeks at 20° C, and there was no evidence of any endophyte in sections examined by electron microscopy.

Fig. 1. Seedling (inside the culture tube) developed from excised embryo of *Podocarpus falcatus*. Note the root nodules (N). ( $\times 0.5$ .)

When the nodules were collected, however, the medium in which cuttings had been rooted was no longer sterile, a result found before<sup>11</sup>. Thus to determine whether or not nodulation is dependent on micro-organisms, excised embryos from full-size green seeds of *P. falcatus* R.Br. were grown *in vitro* on Raghavan and Torrey<sup>13</sup> tissue culture medium. When the chlorophyll had developed in the cotyledons, the embryos were transferred to a mineral agar medium. The seedlings were transferred every 4 weeks to fresh media. When 1 yr old, the roots of the seedlings nodulated (Fig. 1). The structure (Fig. 2c) of the nodules

was similar to that of field grown nodules except that no endophyte was detected in the cortical cells. Malt-'Marmite' agar plates incubated from the crushed nodules remained free of micro-organisms.

These observations suggest that unless nodulation is induced by some undetected endophyte transmitted by the embryo, nodules are a normal feature of the root system of *Podocarpus*, and that their formation is not induced by any microbiological factor. This does not exclude the possibility, suggested before<sup>11</sup>, that such nodules on which the cortex is renewed annually represent an adaptation which allows the mycorrhizal symbiont to be retained after the long roots have shed their cortex.

The idea that nodules are arrested lateral roots<sup>11,12</sup> is not supported by a comparison of the histological features of the young nodule with those of the young lateral root. Both arise endogenously but differ in their cellular configuration. The lateral root, before emergence, clearly shows a recognizable root type apical meristem with the usual open ended endodermis. The nodule, in contrast, shows, before emergence and later, a cell pattern unlike the apical meristem of any root and its new endodermis is not open-ended but over-arches the vascular system of the nodule from the beginning. Thus histologically the nodules do not seem to be modified arrested lateral roots but to be morphological features in their own right.

I thank Drs I. V. Newman and P. G. Valder for their help.

### Holographic Visualization of Plant Movement

HOLOGRAPHIC techniques have been applied to many fields with results which are adequately reported in the literature<sup>1-3</sup>. This communication describes an application of the so-called "frozen" fringe method of holography<sup>4</sup> to the visualization of plant movement or

Fig. 2. Longitudinal section of root nodules of species of *Podocarpus*. Arrows indicate over-arching endodermis. C, Cortex. (a) *P. lawrencei*, field grown nodule, with fungal endophyte in the cortex. ( $\times 65$ .) (b) *P. lawrencei*, sterile nodule from adventitious roots of cutting; absence of endophyte from cortex. ( $\times 65$ .) (c) *P. falcatus*, root nodule from sterile seedling; absence of endophyte. Note the regeneration of nodule at the tip of the vascular branch underneath the endodermis. ( $\times 80$ .)

growth. No attempt has been made to analyse in detail the particular plant movement observed, partly because of the lack of control over the specimen and partly because of the limited time devoted to this experiment. Rather, I wish to show that the method described has a potential use in this field and with correct experimental procedure could yield quantitative results.

A diverging laser beam was used to illuminate the scene which in this case was a pot containing a number of wheat coleoptiles (young shoots) grown in sand. At the time of the experiment the coleoptiles were about 3 cm long and about 2 mm in diameter. The laser was a Spectra Physics, He-Ne model with an output power of about 15 mW.

The Kodak 649F plate film used for the recording received light diffusely reflected from the plants, and these waves were made to interfere with a portion of the incident beam reflected onto the plate from a plane mirror. When this latter reference beam is made to impinge on the developed plate (the hologram), a three-dimensional image of the plants is observed through the plate. This image is produced by a reconstruction of the original wavefronts reflected from the plants. The reconstruction is made possible by the controlled scattering of the reference beam by the silver grain patterns (diffraction patterns) on the developed spectroscopic plate or hologram. The diffraction patterns are created by the interference of the light reflected from the plant and the reference beam. It should be emphasized that the hologram records not only the light amplitude distribution across its plane, but also phase distributions making the reconstructed wavefronts exact replicas of the original wavefronts emanating from the original objects being studied.

With the apparatus used it was found that an exposure of 0.25 sec was suitable to produce a reasonable hologram. The important feature of the "frozen" fringe method, however, is that multiple exposures be made.

Two 0.125 sec exposures were made with an interval of about 30 sec between them. Each exposure can be considered to produce its own train of wavefronts in the reconstruction. If there was no movement of the plant during the time between exposures, then the two trains of wavefronts would be identical, and combine to form a single train which would be indistinguishable from that produced by a single exposure of 0.25 sec. If movement does occur between exposures, however, the wave trains will not coincide and the situation can be analysed by extrapolating back to the position from which they seem to emanate, that is, the virtual images of the plants. If a point on the plant surface moves towards the observer by multiples of a half wavelength of the light being used ( $\lambda = 0.6328\mu$  for the laser used in this experiment) the radiation from the first and second positions will be out of phase and cancel. This point will thus appear dark when the reconstructed wavefronts are viewed. Similarly, if points move by multiples of wavelengths, those points will appear bright. Fig. 1 is a photograph of the virtual image of a coleoptile as seen through a doubly exposed hologram, and shows dark and bright bands which map out the points of the plant surface which have moved by multiples of half and full wavelengths respectively. Measuring the separation of two dark bands on the plant, and knowing that the plant surface moved by a wavelength between them, the tilt of the plant can be calculated as being of the order of 1/2000th of a degree. The result shown in Fig. 1 is quite reproducible, and varying the time interval between exposures gives a different number of fringes.

One point which must be mentioned here is that, for the result shown, the plant surface had to be coated with a matt white paint, because a large percentage of the laser beam penetrates the outer layers of the plant tissue and is reflected from inner layers. The effect of this complicating process is to give extremely weak fringes.

Fig. 1. Banded appearance of a coleoptile indicating movement during a 30 sec interval. (Photographed through a hologram.)

Coating the plant surface prevents this to a large extent. It is extremely debatable whether or not a plant can be coated for a controlled experiment. Researchers who might apply this technique must decide whether or not a coating of powder or paint will interfere with their experiments. Also, from some plant tissues strong reflexions might occur from the outer surfaces with little penetration. Coating in these cases would not be necessary.

A final point worth mentioning is that in some cases the "live" fringe method might be employed, that is, making a single hologram of the plant, and processing and replacing it in exactly the same position in the original apparatus so that the reconstructed image is superimposed on the plant. Any movement of the plant would give rise to fringes which in this case move as the plant moves.

I thank Professor Yemm of the Department of Botany, University of Bristol, for his interest and for the coleoptiles.

### Nomenclature of the "Eastern Lowland Gorilla"

IN discussing the sub-specific taxonomy of the gorilla, Groves<sup>1</sup> has used the name *Gorilla gorilla manyema* Rothschild, 1908, for his eastern lowland sub-species. This procedure is quite contrary to both the International Rules and current practice of taxonomic nomenclature, and if not corrected will inevitably lead to further confusion in the nomenclature of this important and much-studied species. The valid name for this sub-species is *Gorilla gorilla graueri* Matschie, 1914, and the synonymy can be expressed as follows:

*Gorilla graueri* Matschie, 1914 (ref. 2).

*Gorilla gorilla rex-pygmaeorum* Schwarz, 1927 (ref. 3).

*Gorilla gorilla manyema* Groves, 1967 (ref. 1) (following Rothschild, 1908 (ref. 4)).

Groves rejected the name *graueri* because it was based on a slightly atypical montane population, although he stated unequivocally that it was indeed part of the sub-species in question. Rothschild<sup>4</sup>, from whose paper of

1908 Groves claimed to validate the name *manyema*, clearly attributed this name to Alix and Bouvier<sup>5</sup>, who in 1877 described *G. mayema* from the River Quilo, near Landana, lower Congo (that is, in the range of the western gorilla, *G. g. gorilla*). A *lapsus* (an interpretation admitted by Groves), *manyema* of Rothschild therefore has no validity and in any case clearly referred to gorillas from "South Congo Region" which from the context clearly means the lower Congo, south of Gabon, that is, the same region as referred to by Alix and Bouvier. Rothschild nowhere mentioned the upper Congo in connexion with *manyema*.

By deliberately accepting the amended spelling *manyema* with a type locality "Upper Congo", Groves has created a junior synonym of *graueri*, which is dubiously available even in the event of future sub-division of the sub-species because he gave no characters by which his sub-species could be recognized. The supposed holotype on which it is based is a skull with no locality other than "Upper Congo" (British Museum 1939.945). This skull was acquired by Rothschild from a dealer, and although the words "*Gorilla gorilla manyema* Upper Congo" are written on the skull, no details of the specimen were published by Rothschild. This specimen has no standing as the type of any name other than *manyema* Groves, 1967.

### Nomenclature of the "Eastern Lowland Gorilla"

I GREATLY regret that I did not make myself entirely clear in my last communication<sup>1</sup>. Dr Corbet implies that I rejected the name *Gorilla graueri* because it referred to an atypical population; this is not the case. I am well aware that the name would have to stand for the sub-species were it the earliest available name. I tried to show, however, that it is not the earliest available name.

The reasons why I accepted *Gorilla gorilla manyema* Rothschild, 1908, as the valid name for the eastern lowland gorilla may be summarized as follows.

It is not clear to the casual reader of Alix and Bouvier's report<sup>2</sup> whether the locality Landana, on the banks of the Quilo (type locality of their *Gorilla mayema*), is in the (former) Belgian or French area of the Congo region. Elliot<sup>3</sup> clearly thought it was in the Belgian region, as he gives the type locality as "Upper Congo"; it is equally clear that Rothschild also did, as he<sup>4,5</sup> spells the trivial name as *manyema*—an obvious confusion with the province of that name on the Upper Congo. The specimens on which Rothschild based his description must therefore have come from the Upper Congo. Landana is in fact on the Lower Congo: so that the type localities of Alix and Bouvier's *mayema* and of Rothschild's *manyema* are not the same. This prevents the name *manyema* from coming under the heading of Emendation or of Incorrect Subsequent Spelling (International Code of Zoological Nomenclature, Art. 33, *a* and *b*), for the taxon referred to by Alix and Bouvier and by Rothschild was not the same. Also the name is not a homonym, because the difference of a single letter is sufficient to prevent homonymy (Art. 57, *d*).

In two papers, Rothschild describes his *G. g. manyema* with the characters of the Eastern lowland gorilla. In 1908 he says<sup>4</sup>, "I have recently received an adult male skull and photograph which clearly show that the Congo gorillas have . . . very sharply defined pale and dark

areas in the pelage"; while in 1923 (ref. 5) he states, "the two or three adult males examined . . . appear to have the pelage brighter in colour and more sharply contrasted". This corresponds to the difference between the eastern gorillas (both *G. g. manyema* and *beringei*) and their western relative: in the former the white "saddle-patch" of the adult male is very sharply defined from the jet black of the surrounding pelage, while in the western gorilla there is a much more gradual change. So Rothschild is clearly describing an eastern gorilla.

Rothschild never mentions more than one skull of *manyema* in his collection. He says that it is<sup>4</sup> "a still narrower and more elongated skull than those from Gabon". This is true of *B.M.* No. 1939.945 which in my communication I accepted as Rothschild's holotype: it measures 305 mm in inion-prosthion length, and 144 mm in cranial breadth, while the mean of nine Gabon skulls, all of the Rothschild collection in the British Museum, except for one which is still in Tring, is 286 mm in length and 138 mm in breadth. The Rothschild skull is certainly "narrower and more elongated". Not only is the inscription "Upper Congo" written on the skull, but application of the results of the statistical analysis to it shows that without a doubt it belongs to the Eastern lowland sub-species, most likely of the Utu deme.

This further information may make my decision to use the name *manyema* a little clearer than in my original paper; reading my paper along it is not surprising that Dr Corbet had concluded that I was at fault. It remains to be pointed out that the name *manyema* is not a *nomen oblitum* as Rothschild used it in 1923, less than fifty years ago. It is to be hoped that all is now settled satisfactorily.

### Contraceptive Action of Intrauterine Devices in the Rhesus Monkey

Kelly and Marston<sup>1</sup> have provided important information on the influence of the intrauterine device (IUD) on the distribution of ova in the spontaneously ovulating monkey.

They refer to our report<sup>2</sup> in which the influence of an intrauterine coil on ovum distribution was studied in the superovulated rhesus monkey. In this series, a 50 per cent rate of recovery of tubal ova was noted in control animals without coils. Among similarly treated animals with coils no ova were recovered from the fallopian tubes but four unfertilized ova were found in the uterine cavity. Unlike the animals used by Kelly and Marston all animals in this series were superovulated with gonadotropin, and the IUD was applied by the vaginal route. These studies have now been extended. Among eleven animals with coils which had forty-nine ovulation points, no tubal ova but seven uterine ova were recovered. The non-coil group revealed fifty-five ovulation points, sixteen tubal ova and no uterine ova. Thus, in the superovulated monkey, the coil appears to speed the rate of transfer of ova from the tube, and ova are not extruded promptly from the uterine cavity. Kelly and Marston did not find ova in the uterus in their coil group which had ovulated spontaneously.

Among spontaneously ovulating coil monkeys recently studied in our laboratory, tubal ova have been recovered. Thus our recent data<sup>3</sup> also support the conclusion that in the spontaneously ovulating animal, ova are not delivered

to the uterus immediately after arrival in the tube. The time relationship between ovulation and entry into the uterine cavity is, however, worthy of further scrutiny. A 12–24 h difference in the duration of tubal life may be crucial in terms of ability to implant.

Inasmuch as in our initial series superovulation was used, the evidence of Kelly and Marston does not “contradict” our findings. Their published studies and our studies in the spontaneously ovulating animal reveal findings which are substantially different from those obtained in the superovulated monkey. The mechanism behind the postulated enhanced speed of tubal transport in the superovulated coil animal is of great interest and worthy of further study.

## PHYSIOLOGY

### Diffusion Coefficient of Oxygen through Tissues

THE measurement of the diffusion coefficient of oxygen through actively respiring tissue is of considerable interest but presents some practical difficulty. From the work of Krogh in 1918 until the present time, a very wide range of values for oxygen diffusion coefficients has been reported<sup>1–5</sup> ranging from  $1.1 \times 10^{-4}$  to  $4 \times 10^{-8}$  cm<sup>2</sup> sec<sup>-1</sup>. Because of this very wide range of reported values we decided to measure this value again by a technique essentially similar to that described by Longmuir<sup>5</sup>, but with the difference that the measurements were made on one slice of tissue at a time without the intrusion of “edge” effects.

Tissue slices were cut under sterile conditions to 1.5 mm thickness either by hand or using a tissue slicer and the slices were then cultured in 20 per cent horse serum in ‘Medium 199’ by the organ culture method of MacDougall and Coupland<sup>6</sup>. The external oxygen tension was controlled at a steady value between 0.2 and 3.0 atmospheres pressure. The slices were left for periods varying between 4 h and 5 days at 37° C. It was found that a sharp differentiation between a superficial compact layer of approximately normal cells and a central area of obviously abnormal cells was evident as early as 8 h after slicing.

At the conclusion of an experiment, the tissues were fixed in Bouin’s solution and 8 $\mu$  paraffin sections were prepared and stained with Ehrlich’s haematoxylin and eosin. During the processing care was taken to ensure that the block of tissue was embedded so that subsequent sectioning took place at 90° to the plane of the tissue surface which had been in contact with oxygen. In some instances this surface was marked for identification with indian ink.

Measurement of the thickness of the superficial compact zone was carried out by microscopy using a calibrated eyepiece. In expressing the results allowance was made for a 20 per cent shrinkage of the tissue by the histological processing. This value was previously determined on similar tissue samples.

The results obtained using slices of rat liver are shown in Table 1. Warburg’s equation<sup>7</sup> relates the concentration of oxygen outside the tissue slices to that at any point inside the tissue in terms of the diffusion coefficient of oxygen and the respiration rate of the tissue, that is,

$$U = C - \frac{a}{2D} (Hx - x^2)$$

where  $U$  is the oxygen tension in atmospheres at a point distance  $x$  cm inside the surface,  $C$  is the external oxygen tension in atmospheres,  $a$  is the respiration rate of the tissue (in ml. of oxygen consumed/min./ml. of tissue),  $H$  is the slice thickness in cm and  $D$  is the diffusion coefficient for oxygen in Krogh’s units.

From this equation it can be shown that oxygen will diffuse into a slice of respiring tissue to a depth  $x$  given by

$$x = \left( \frac{2D}{a}, C \right)^{\frac{1}{2}}$$

Thus a plot of  $x^2$  against  $C$  should give a straight line of slope =  $\frac{2D}{a}$ , which passes through the origin. The results are shown plotted in this way in Fig. 1.

Table 1. SHOWING THE THICKNESS OF THE SURVIVING ZONE AS A FUNCTION OF THE OXYGEN PARTIAL PRESSURE DURING INCUBATION

PO <sub>2</sub> (atmospheres)	$x^1$ (cm)	$x$ (cm)	$x^2$ (cm <sup>2</sup> ) $\times 10^{-4}$
0.2	0.007	0.0087	0.76
0.6	0.018	0.023	5.3
1.0	0.020	0.025	6.25
1.5	0.025	0.031	9.6
2.0	0.030	0.0375	14.0
3.0	0.034	0.0425	18.0

$x^1$  is the measured value of the fixed and stained compact zone and  $x$  is this value corrected for shrinkage during the preparation of the slices.

In deriving his equation Warburg made the simplifying assumption that the affinity for oxygen of the terminal oxidases in the tissues is infinite. Clearly, this is not the case; while the oxygen “ $K_m$ ” needed for cytochrome oxidase is of the order of only a few millimetres of mercury<sup>8</sup>, the flavoprotein oxidases and oxygenases which contribute up to 10 per cent of the total respiration have very low oxygen affinities, that is,  $K_m$ ’s of about 150 mm of mercury of oxygen<sup>9</sup>. This makes it difficult to select a theoretically justifiable value for “ $a$ ”, the respiration rate; however, in measuring the thickness of the surviving layer it has been observed that a vacuolated zone of poorly surviving cells (see Fig. 2) lies inside the compact layer of cells of normal appearance and it is suggested that this layer represents a zone where some oxygen is supplied to the tissue but at a partial pressure insufficient for the optimal functioning of the mitochondria. Thus it seems probable that all of the zone which is measured is respiring at, or very near to, its maximum rate under the experimental conditions. This respiration rate has been measured, using very thin slices and with the same substrate, in a Cruickshank differential micro-respirometer which has the advantage that the conditions of measurement closely resemble the conditions of culture.

Fig. 1. Showing the relationship between the thickness (squared) of the surviving tissue and the external oxygen pressure during culture.

Fig. 2. Sections of liver cultured for 24 h at the oxygen pressures shown (in atmospheres absolute). Note the increasing thickness of the surviving compact zone with increasing oxygen pressure. F.T. is a section of fresh tissue for comparison. Haematoxylin and eosin,  $\times c. 68$ .

Substitution of a mean value for these results in the equation gives a value for  $D$  of  $5.2 \times 10^{-5}$  Krogh units. These units of diffusion coefficient are related to the more usual Fick units by the relation  $D_f = \frac{Dk}{60\alpha}$ , where  $\alpha$  is

the absorption coefficient of the gas in the tissue expressed in ml. gas/ml. tissue at the temperature of the experiment.

The value for  $D$  ( $O_2$ ) Fick obtained is shown in Table 2 together with several other values obtained from other sources.

Source (ref. No.)	Tissue	$D_f$ ( $O_2$ ) $cm^2 \text{ sec}^{-1}$
10	Water (25° C)	$2.12 \times 10^{-5}$
1	Rat diaphragm (37° C)	$1.4 \times 10^{-5}$
12	Bacteria	$4 \times 10^{-6}$
5	Rat liver (37°)	$1.1 \times 10^{-4}$
This work	Rat liver (37°)	$3.6 \times 10^{-5}$

It can be seen that the value is somewhat higher than that through free water<sup>10</sup> and also higher than the value obtained by Krogh<sup>1</sup>, but rather lower than the results of Longmuir<sup>5</sup>.

It is not difficult to imagine a facilitated transport of oxygen through cells as the actively respiring mitochondria have a pumping action which promotes microturbulence of the cell protoplasm. Also the presence of haem like groups may facilitate the transport of oxygen across the cells and these factors may account, as Longmuir has suggested<sup>5</sup>, for a value higher than that through free water.

On the other hand Krogh's experiments were conducted with slices of tissue exposed to haemoglobin solution which has been shown to be toxic for several tissues<sup>11</sup> while the experiments of A. V. Hill<sup>2</sup> were performed on muscle just recovering from a period of anoxia. Thus in both these experiments one might well expect a reduction of the metabolic activity of the cells including protoplasmic stirring.

The experiments of Longmuir, on the other hand, were conducted in virtually optimum conditions for respiratory activity because his slices were well oxygenated and the substrate used was carefully chosen for maximum respiration rates; and it may be that his higher values (approximately three-fold higher) are related to the higher respiration rate (approximately six times greater) of his biological system.

This work was supported by a grant from the Medical Research Council.

### Inhibitory Action of Sodium Ions on Transmitter Release at the Motor End-plate

SEVERAL inorganic cations are important in the liberation of acetylcholine during neuromuscular transmission. Extracellular calcium ions are essential for the transmitter release during the depolarization of the nerve terminals<sup>1</sup>. The mean number of packets of transmitter liberated (quantal content  $m$ ) depends on the external concentration of calcium<sup>2</sup>. In this process magnesium ions compete with calcium ions<sup>3</sup>. Extracellular sodium ions also take part in the process of transmitter release by the nerve impulse. A reduction in the extracellular sodium concentration produces a large increase in the end-plate potential amplitude, and in  $m$ , at least under conditions of low external concentrations of calcium (refs. 4 and 5).

The effects of calcium and magnesium ions on the transmitter release by a nerve impulse have been ascribed to reactions between calcium (or magnesium) ions and a specific site  $X$  on the nerve terminal, forming  $CaX$  (or  $MgX$ ); while  $CaX$  is necessary for the release,  $MgX$  is ineffective<sup>6</sup>. It has been suggested that the effect of sodium ions can be explained in a similar way, that is, that calcium and sodium ions compete for this "strategic site" at the presynaptic membrane<sup>4,5</sup>. At low concentrations of calcium the e.p.p. amplitude (or  $m$ ) is a fourth power function of the presumptive  $[CaX]$  complex<sup>7,8</sup>. On the basis of these results it was concluded that the process of liberation of a quantum of transmitter requires a co-operative action of four calcium ions.

Thus there are at least two possible alternative explanations for the inhibitory action of sodium ions on transmitter release: they can either compete with calcium for the presumptive  $X$  sites, or they can change the number of calcium ions required for release. With normal concentrations of calcium, co-operation of four calcium ions is necessary to release a unit of acetylcholine<sup>7,8</sup>. If in low concentrations of sodium a co-operative action of a smaller number of calcium ions is needed, then the probability of release would be increased. To decide between these possibilities, the quantitative relationship between the concentration of calcium and release, at normal and low concentration of sodium, was examined.

End-plate potentials from surface fibres of frog sartorius muscle were recorded intracellularly with potassium chloride micropipettes. Conventional d.c. amplifier, cathode ray oscilloscope and photographic records were made. All experiments were performed at room temperature (19°–24° C). Solutions containing low concentrations of sodium ions were prepared by isotonic substitution of sucrose for sodium chloride. The experiments were performed in low extracellular concentrations of calcium ions; end-plate potentials were therefore fluctuating in amplitude (Fig. 1) as predicted by the quantal hypothesis<sup>9</sup>. In order to obtain a statistically reliable measure of  $m$ , a large number of end-plate potentials was averaged (256 when  $m$  was less than 3, 128 when  $m$  was between 3 and 10, and 64 when  $m$  was greater than 10). This was usually done by means of a computer for averaging transients ('Biomac 500').

Fig. 1. End-plate potentials at normal (left) and low—60 per cent (right) concentrations of sodium.  $A_1$  and  $A_2$  are samples of individual records.  $B_1$  and  $B_2$  are automatically averaged responses to 256 stimuli. Averaging step 80  $\mu$ sec. Magnesium ions (2 mmolar) were present throughout the experiment.

When lowering the concentration of sodium, end-plate potential amplitudes are not a reliable measure of the amount of transmitter release, because there is a decrease in the postsynaptic sensitivity to acetylcholine<sup>10,11</sup>. This was also seen when measuring the mean amplitude of the miniature end-plate potential ( $\bar{a}$ ). It is interesting that in addition to the immediate reduction of  $\bar{a}$  after changing the medium to 60 per cent sodium, there was an additional slow reduction of  $\bar{a}$ . While the initial diminution in  $\bar{a}$  is probably caused by changes in the equilibrium potential<sup>11</sup>, the explanation of the second phase of decrease is still obscure. For this reason, in the subsequent analysis, only direct determinations of  $m$  were accepted as a measure of transmitter release. These were obtained from the ratio of the average end-plate potential and  $\bar{a}$  (ref. 9), which requires that all the experiments were made on uncurarized preparations.

The records in Fig. 1 illustrate the inhibitory effect of sodium ions on transmitter release. Decreasing the concentration of sodium ions from normal (116 mmolar) to 60 per cent of the normal (69.6 mmolar) causes the mean end-plate potential amplitude to increase by 87 per cent, and  $m$  to increase by 142 per cent (there was a simultaneous 23 per cent decrease in  $\bar{a}$ ). Qualitatively, these are similar to earlier results<sup>4,5</sup>.

The quantitative relation between calcium and release was examined at the same end-plate at normal and low concentrations of sodium (Fig. 2A). The non-linear relations obtained are similar to those reported before<sup>3,7,8</sup>.

It has been suggested<sup>8</sup> that the relation between calcium and release follows a co-operative equation

$$m = K \left( \frac{\text{Ca}}{1 + \frac{\text{Ca}}{K_1} + \frac{\text{Mg}}{K_2}} \right)^4 \quad (1)$$

where  $K_1$  and  $K_2$  are dissociation coefficients of  $\text{CaX}$  and  $\text{MgX}$  complexes, respectively, and  $K$  is a constant. It should be noted that in equation (1) no account is taken of possible competitive interactions between ions other than magnesium and calcium; if there is competition between sodium and calcium, this would give a spurious value of  $K_1$ .

In order to test whether sodium ions affect the power index between calcium and  $m$ , or one of the other para-

Fig. 2. Relation between concentration of calcium ion and  $m$  at 100 per cent (O) and 60 per cent (●) concentrations of sodium. All points obtained at the same end-plate. Each point represents the average response to 256, 128 or 64 stimuli. (A) Linear plot; (B) same as A on double-logarithmic co-ordinates. Magnesium (1 mmolar) was present throughout the experiment.

Table 1. EFFECT OF REDUCING THE CONCENTRATION OF SODIUM ON  $m$ 

	1 mmolar magnesium	8 mmolar magnesium
Average quantal content at normal [Na]—	11.08	0.64
$m_{1.0}$	(64)	(256)
Average quantal content at low [Na]—	27.62	0.79
$m_{0.4}$	(64)	(256)
$m_{1.0}$	2.49	1.24

The concentration of calcium was kept at 0.4 mmolar. Numbers in parentheses are averages of responses.

meters of equation (1), the experimental results were plotted on log-log scale (Fig. 2B). The resulting straight lines in low and high concentrations of sodium have almost the same slope, indicating that sodium ions do not change the power relationship between calcium and  $m$ , but only shift the relation along the abscissa. Thus it can be concluded that the requirement for a co-operative action of four calcium ions is not altered even in low external concentrations of sodium, when the release is greatly augmented. The observed shift in the log calcium-log  $m$  relation could result either from an effect of sodium on the parameter which determines the maximal release ( $K$ ), or by competition between sodium and calcium (and therefore also with magnesium) in combining with  $X$ .

In this respect some evidence was obtained by studying the interaction between sodium and magnesium ions, at a constant calcium concentration. If sodium ions compete with calcium and magnesium for  $X$ , then this would lead to equation (2)

$$m = K \left( \frac{Ca}{1 + \frac{Ca}{K^*_1} + \frac{Mg}{K_2} + f(Na)} \right)^4 \quad (2)$$

where  $f(Na)$  is a function of  $[Na]$  or  $[Na]^2$  and  $K^*_1$  is the "true" dissociation coefficient of  $CaX$  complex. From equation (2) it is expected that the increase in  $m$  caused by reduction in the concentration of sodium would be smaller at high than at low concentrations of magnesium. Table 1 shows that this is so. While reducing the concentration of sodium at 8.0 mmolar magnesium produces only a 24 per cent increase in  $m$ , at 1.0 mmolar the increase is 149 per cent. It is suggested therefore that the inhibitory effect of sodium ions on transmitter release arises from competition with calcium ions on the postulated critical sites  $X$ .

### Unitary Excitatory Postsynaptic Potentials in Clarke's Column Neurones

It is generally believed that synaptic transmission is effected by a quantal release of transmitter substances, such as has been demonstrated for the neuromuscular junction<sup>1</sup>. The quantal nature of synaptic transmission in the central nervous system is more difficult to investi-

gate, one reason being that many presynaptic fibres usually contribute to the EPSP (excitatory postsynaptic potential), whereas at the neuromuscular junction the entire effect is evoked from a single presynaptic fibre. Thus at central synapses the total synaptic action should be described both in terms of the number of unitary EPSPs (the EPSP contributed by a single presynaptic fibre) and the quantal composition of each unitary EPSP. In motoneurones, impulses in Ia afferents (large muscle spindle afferents) usually evoke small unitary EPSPs with a low quantal content<sup>2</sup>, but larger unitary Ia EPSPs with quantal content "possibly as high as ten or fifteen" have also been found<sup>3</sup>.

The work reported here deals with transmission to Clarke's column cells giving rise to the dorsal spinocerebellar tract. These cells are effectively monosynaptically activated from primary afferents, some from Ia afferents<sup>4</sup>. Previous recordings of the EPSPs in Clarke's column cells evoked by graded stimulation of muscle afferents show a large convergence (about twenty presynaptic fibres) and suggest small unitary EPSPs (less than 1 mV)<sup>5</sup>. From an analysis of the irregularity in firing in response to muscle stretch, on the other hand, it has been suggested that large unitary EPSPs may exist in Clarke's column cells<sup>6</sup>.

The experiments were performed on spinal cats, anaesthetized with chloralose and immobilized with 'Flaxedil'. One hindlimb was denervated except for the nerves of the ankle muscles. The tendons of these muscles were cut near their insertions and by means of threads and pulleys the individual tendons could be loaded with weights. Intracellular records of Clarke's column cell were obtained in spinal segments LIV to LII by micropipettes filled with potassium citrate or potassium chloride. All neurones were identified by antidromic activation from the dissected dorsolateral funicle of the cord and by group I monosynaptic activation from one of the muscle nerves.

The impaled cells analysed had a resting membrane potential of 35–60 mV. At the lower levels the spike mechanism was inactivated, but local responses occurred which could be confused with "synaptic noise". When the cells were hyperpolarized this "noise" disappeared and a resting discharge occurred. For the analysis of unitary EPSPs the cells were hyperpolarized to a level at which no firing was produced by a moderate muscle stretch. Stronger hyperpolarization was used to prevent the firing evoked by a synchronous group I volley in muscle afferents. A maximal volley may produce an EPSP of 25–30 mV. Graded stimulation reveals steps of widely different sizes. We found it difficult to determine the exact degree of convergence with this technique but have confirmed that there is a considerable degree of convergence of primary afferents onto each Clarke's column cell. A more convenient technique in the study of unitary EPSPs is to investigate the asynchronous effect of muscle stretch<sup>7</sup>. The records in Fig. 1 are from a cell that was monosynaptically activated by group I afferents from the soleus muscle. With the tendon slack there were only very small fluctuations in membrane potential. A load of 20 g on the tendon produced rhythmic short-lasting depolarization consisting of a rapid rising phase followed by a slower approximately exponential return to the resting level (Fig. 1A). They have all the characteristics of unitary EPSPs produced by afferent impulses from muscle stretch receptors. Their time course resembles that of the electrically evoked EPSP and they occur at very regular intervals as long as the muscle stretch is constant (compare interval distribution in Fig. 1C). From its amplitude and time course the unit of Fig. 1A could be recognized at a higher degree of muscle stretch (Fig. 1B). Its rate of appearance is higher and now it appears alternately with other units of smaller amplitude. When coinciding in time the EPSPs summate. The mean amplitude of the large unitary EPSP in Fig. 1A is 4.3 mV.

Three other unitary EPSPs of the same cell identifiable by the rhythmicity and time course had mean amplitude of 2.4, 1.8 and 1.4 mV. Unitary EPSPs of smaller size, which were difficult to identify individually, were frequently evoked by stretch.

Other group I activated Clarke's column cells showed an appreciable unitary synaptic activity even with the activating muscle slack. Such resting activity may originate in muscle stretch receptors because primary endings of the muscle spindles commonly have a resting discharge in the slack muscle. We could usually demonstrate that a greater part of the resting synaptic activity did originate in the muscle stretch receptors by its disappearance in the period immediately following release of the muscle from a strong pull. In the cells with a resting synaptic activity it was difficult to recognize the individual unitary EPSPs evoked by muscle stretch.

We conclude that many primary afferents contribute excitatory action to each Clarke's column cell. The unitary EPSPs range from a maximal size of about 5 mV down to a fraction of 1 mV.

The amplitude of a unitary EPSP shows appreciable fluctuations (Fig. 1A). Assuming that the release of the quanta of transmitter occurs with a certain probability the fluctuation in amplitude of an individual unitary EPSP is a function of the number of quanta released by each presynaptic action potential. If the average probability of release of an individual quantum is small the number of quanta released and accordingly the distribution of amplitudes of an individual unitary EPSP are described by Poisson's distribution. Without any information on the size of the individual quanta in the unitary EPSP of the Clarke's column cells the estimation of their quantal content could be based on the frequency of occurrence of complete failures in a rhythmic series like that of Fig. 1. We found no failures in our observations of unitary EPSPs. The unit of Fig. 1A was followed for more than 450 occurrences, and the absence of failures gives only an estimate of the minimal quantal content of more than seven.

In the absence of failures the quantal content ( $m$ ) can be estimated from the coefficient of variation

$$CV = \frac{S.D.}{\text{Mean}}$$

Fig. 1. Intracellular record from Clarke's column cell. The resting membrane potential was 60 mV and the cell hyperpolarized by passage of 10 nAmp through the recording microelectrode. A, Rhythmic unitary EPSP evoked by a load of 20 g on soleus tendon. B, Same as A with a load of 50 g on soleus tendon. The largest unitary EPSP is marked with dots, and is the same as that in A. C, Distribution of intervals between consecutive unitary EPSPs, measured from record like A with a load of 20 g on tendon. Ordinate, No. of observations in each class. Abscissa, duration of intervals. Class size 5 msec. D, Distribution of amplitudes of unitary EPSPs of A. Total No. of observations 151. Mean amplitude 4.3 mV. S.D. 0.42 mV. Ordinate as in C. Abscissa, amplitude of EPSP.

of the distribution of amplitudes. In the simplest case<sup>7</sup> the relationship is the following

$$m = \frac{1}{(CV)^2}$$

Fig. 1D illustrates the distribution of amplitudes of the unitary EPSP of Fig. 1A. The distribution is fairly symmetrical and approximately Gaussian. Because the Poisson distribution approximates the normal distribution for large average numbers of events, the form of the amplitude distribution indicates that many transmitter quanta are liberated by each presynaptic impulse. The mean amplitude of the EPSP of Fig. 1D was 4.3 mV and the S.D. 0.42 mV. This gives quantal content of approximately 100. For five other large unitary EPSPs the CV varied between 16 and 11 per cent, which corresponds to a mean quantal content of 39 to 83. The estimates are subject to the assumption of a Poisson law governing quantal transmitter release and certain additional approximations<sup>7</sup>. It seems reasonable to accept the Poisson model because it has proved adequate at the neuromuscular junction where its implications have been tested directly. The accuracy of the present estimate of  $m$  is reduced by a number of factors<sup>7</sup>. A rough appreciation of the importance of these suggests that the true number of quanta released is not less than half of the estimate. Accordingly, the number of quanta released by an impulse in a group I afferent fibre producing a large unitary EPSP in a Clarke's column cell would be at least between 20 and 50. Such a large quantal content, perhaps half of that released by an impulse at the mammalian neuromuscular end-plate, might be correlated with the extensive synaptic contacts between primary afferent fibres and Clarke's column cells<sup>8</sup>.

### Influence of Denervation on Localization of Neurotoxins from Clapid Venoms in Rat Diaphragm

$\alpha$ -BUNGAROTOXIN<sup>1,2</sup> isolated from the venom of *Bungarus multicinctus*, as well as cobra neurotoxin<sup>3,4</sup> from the venom of *Naja naja atra*, has been found to block neuromuscular transmission by an antidepolarizing action similar to that of *d*-tubocurarine. These conclusions have been further supported by the autoradiographic findings that  $\alpha$ -bungarotoxin labelled with iodine-131 (ref. 5), as well as cobra neurotoxin<sup>6</sup>, accumulates on the motor end-plate zone of the mouse diaphragm in the same way as *d*-tubocurarine<sup>7</sup>.

In the rat diaphragm preparation treated with either labelled  $\alpha$ -bungarotoxin ( $5 \times 10^{-6}$  g/ml.) or cobra neurotoxin ( $10^{-6}$  g/ml.) *in vitro*, the radioactivity on the motor

Fig. 1. Effect of phrenicotomy on fixation by  $\alpha$ -bungarotoxin labelled with iodine-131 after 14 days (a) and 60 days (b). Right side: innervated hemidiaphragm; left side: phrenicotomized hemidiaphragm. Each rat was injected subcutaneously with 0.3  $\mu$ g/g of  $\alpha$ -bungarotoxin and died at 75 min (a) and 110 min (b) respectively after the injection.

end-plate zone remained unchanged even after more than 4 h of washing with Tyrode solution, whereas the portion of toxins taken up non-specifically by the muscle tissue other than the motor end-plate zone disappeared almost completely after washing. This finding is consistent with the irreversible nature of the neuromuscular block by these toxins.

By cutting the left phrenic nerve we examined the influence of denervation on the localization of these toxins in the rat diaphragm. At 14 and 60 days respectively after phrenicotomy, the labelled toxins were injected subcutaneously in a dose of 0.3  $\mu$ g/g body weight and the autoradiograph of the denervated side was compared with that of the intact right side of the diaphragm. In the hemidiaphragms denervated for 14 days, the radioactivity spread over the whole area of the muscle tissue, although a well defined motor end-plate zone could still be distinguished (Fig. 1a). This finding, together with that of Waser<sup>8</sup> using C14-curarine, gives support to the contention that supersensitivity of denervated muscles to acetylcholine results from an increase in the receptor area rather than from a marked change in the receptors themselves<sup>9,10</sup>. In contrast to the finding of Waser<sup>8</sup> that in the denervated diaphragms the radioactivity disappeared completely within 60–120 days, we found almost the same pattern of localization of radioactivity in the hemidiaphragm denervated for 60 days (Fig. 1b).

### Progesterone in Cerebrospinal Fluid during Human Pregnancy

PROGESTERONE has been found to be an effective anaesthetic agent when given intraperitoneally to animals<sup>1,2</sup> and 21 hydroxy pregnandione succinate has been used clinically for general anaesthesia<sup>3</sup>. Of practical importance in clinical anaesthesia is the fact that in animals progesterone potentiated the effect of ether and chloroform<sup>2</sup>.

No clinical confirmation of this effect in humans is, however, available. Paradoxically, it is believed that progesterone renders the respiratory centre more sensitive to carbon dioxide and that this may account for the lowered  $p\text{CO}_2$  in blood during pregnancy.

In view of the higher concentration of progesterone in the peripheral circulation during pregnancy and the apparent lack of clinical effects on the central nervous system, we were interested to obtain some information concerning the concentration of progesterone in the cerebrospinal fluid especially in pregnancies approaching term. A search of the literature revealed that this information had not previously been reported.

The method which we used to assay the progesterone in cerebrospinal fluid was identical to that used for plasma<sup>4</sup>. The highest reliable sensitivity obtained with the method was 0.004  $\mu$ g/ml. Using this method we confirmed that the concentration of progesterone in the peripheral blood rises progressively during pregnancy and that there is no reduction in concentration until separation of the placenta<sup>5</sup>. It is now generally believed that there is no reduction of progesterone in the peripheral blood before the onset of labour at term.

Peripheral blood and cerebrospinal fluid were obtained at the same time from each of four patients at term. In each case the cerebrospinal fluid was obtained before the administration of spinal anaesthesia. The results of the assays are shown in Table 1.

Table 1		
Patient	Progesterone in plasma ( $\mu$ g/100 ml.)	Progesterone in cerebrospinal fluid ( $\mu$ g/100 ml.)
A	10.00	Undetectable
B	8.74	0.30
C	9.00	0.55
D	11.10	Undetectable

The results strongly suggest that there is an effective blood-brain barrier for progesterone and this may explain the lack of apparent effect on the central nervous system as pregnancy advances. The marked difference in concentration of progesterone has also been shown to exist for cortisol<sup>6</sup>, and it is interesting that the concentration of cortisol found by Baron and Abelson in cerebrospinal fluid is similar to that reported here for progesterone.

### Effects of Norepinephrine on Tissues of the Frog Heart Atrium poisoned by Tetrodotoxin

THE acceleration of the sinus venosus of the frog's heart induced by epinephrine may be the result of an increase in the conductance of sodium<sup>1</sup>. We also know that the action potential of the frog atrium is abolished in sodium

free solutions<sup>2</sup>. We have tested the effects of tetrodotoxin on these responses because this poison selectively blocks the increase in the conductance of sodium which is responsible for the generation of action potentials in many tissues<sup>3</sup>.

The excised frog atrium and sinus venosus were immersed in oxygenated Ringer's solution (115 mmolar sodium chloride; 3 mmolar potassium chloride; 1.0 mmolar calcium chloride; 2.0 mmolar sodium bicarbonate; and 0.05 mmolar sodium phosphate, pH 7.2). We used pairs of small platinum wires for stimulation and extracellular recording. Intracellular recordings were made by means of conventional microelectrode techniques.

When  $10^{-8}$  g/ml. of tetrodotoxin was added to the bath the electrical activity of atrial muscle was abolished without eliminating the initiation of impulses at the sinus venosus (Fig. 1A and B). In the experiment illustrated here, the rate of activity in the sinus venosus decreased from 44 to 28 beats/min after the addition of tetrodotoxin. When norepinephrine ( $5 \times 10^{-6}$  g/ml.) was added, the sinus rate increased to 47 beats/min. More striking than the increase in rate was the recovery of excitability of atrial muscle. It now propagated action potentials in response to impulses from the sinus venosus (Fig. 1C) or to electrical stimuli.

The propagation in the atria treated with tetrodotoxin plus norepinephrine was sluggish. In the experiment illustrated in Fig. 1, the conduction time before treatment was 80 msec. After treating the preparation with tetrodotoxin plus norepinephrine the time was 400 msec. In two other preparations a similar prolongation of conduction time was observed.

The most striking effect observed in intracellular records of atrial muscle treated with tetrodotoxin plus norepinephrine was a slowing of the rate of rise of the action potential (Fig. 2A and B). In nineteen cells in three atria penetrated before treatment the rate of rise was  $37.7 \pm 11.4$  V/sec (mean  $\pm$  S.E.). In eighteen cells of the same atria impaled after adding  $10^{-8}$  g/ml. of tetrodotoxin plus  $5 \times 10^{-6}$  g/ml. of norepinephrine the rate of rise was  $8.1 \pm 3.5$  V/sec.

The minimal dose of norepinephrine sufficient to recover atrial excitability varied between 2 and  $8 \times 10^{-6}$

Fig. 2. Intracellular records of two cells of the same atrium. The upper tracing is the action potential. A horizontal line was drawn through the zero potential level. The lower tracing is the electrically differentiated record of the action potential. (Time constant of the differentiating network: 100  $\mu$ sec.) (A) Control; (B) after treatment with tetrodotoxin plus norepinephrine.

g/ml. In several experiments, we tried to find whether this minimal dose of norepinephrine necessary for recovery was modified by varying the concentration of tetrodotoxin. We found that the minimal dose of norepinephrine that caused a given atrium to recover was not altered by increasing the tetrodotoxin from  $10^{-8}$  to  $10^{-6}$  g/ml.

Of the most likely explanations for these results are: (a) much of the acceleration of sinusal rate caused by norepinephrine results either from an increase in the conductance of sodium through a site insensitive to tetrodotoxin or from a change in conductance to an ion other than sodium; (b) in atrial muscle norepinephrine increases the voltage dependent changes in conductance through sites different from those carrying the currents responsible for the normal action potential. An alternative explanation would be that norepinephrine restores in a non-competitive manner the ability of the site poisoned with tetrodotoxin to increase the conductance of sodium ions in response to depolarization of the membrane.

Fig. 1. Tracings of the extracellular activity of the excised atrium. (A) Control record: the sinusal action potential (s) and atrial muscle action potential (a) can be clearly distinguished. (B) After the addition of  $10^{-8}$  g/ml. of tetrodotoxin, the atrial muscle action potential is abolished while spontaneous sinusal activity continues, although at a lower rate. (C) After treatment with norepinephrine ( $5 \times 10^{-6}$  g/ml.) the sinusal rate increased and the atrial muscle propagated impulses again.

## Interaction of "Stress" and the Response to Mescaline

THE clinical effect of mescaline is very variable both between different subjects and in the same subject at various times. One factor that has been noted to play a part here is the anxiety proneness of the subject. Klerman<sup>1</sup> has shown in a double blind study that passive, anxious, intellectual introverts react in a far more psychotic manner to mescaline than do non-anxious extroverts. Our clinical experience confirms this.

The formula of mescaline suggests that it might act on some biochemical mechanism concerned with the catecholamines—in particular catechol-O-methyl transferase. There might therefore be an exacerbation in its effects

if we increase the central adrenergic activity associated with anxiety. In order to gain further data on this point we have investigated in the rat the effect of mescaline on a stable behavioural baseline before and after the instigation of the conditioned emotional response (CER). Previous to this, experiments in our laboratory had shown that on positive reinforcement schedules, animals with prior negative reinforcement history (Sidman avoidance) showed a much heightened susceptibility to the effects of mescaline.

In the experiments described a rat deprived of water is first trained to press a lever for water reward on a differential reinforcement of a low rate, limited hold (DRL-LH) schedule. Fig. 1A shows the response obtained after more than 100 daily training sessions. The rat is now producing a characteristic DRL type inter-response time distribution with a mode around the lower bound of the reinforced interval. Fig. 1B shows that a dose of 8.5 mg/kg mescaline intraperitoneally has no effect on this lever-pressing response. A higher dose of mescaline (at least 12.5 mg/kg) will induce a dose dependent period of inhibition with time of onset between 5 and 10 min after injection. The CER was then established by repeated presentation of a 2 min buzzer conditioned stimulus (CS) terminated by brief electric shock (0.5 m.amp, 0.5 sec). Response shock pairings were preceded by habituation to the conditioned stimulus and CER procedure was maintained for forty daily sessions. The rat quickly adapts by complete suppression of lever pressing during the CS periods but with no apparent disruption of the baseline behaviour (Fig. 1C).

Fig. 1D shows that mescaline (at the previously inactive dose level) now has a profound effect on behaviour, suppressing all responding for about 30 min. The figures show the response of one animal from a group of three,

Fig. 1. The effects of 8.5 mg/kg mescaline before and after the establishment of the conditioned emotional response. Pre-CER: Each response step the record in the vertical direction. A downward slash indicates reinforcement. A, Control saline injection; B, 8.5 mg/kg mescaline intraperitoneally. Post-CER: In the top record periods of deflection represent the 2 min CS presentations. Reinforcements are shown on the bottom horizontal record. C, Control saline injection; D, 8.5 mg/kg mescaline intraperitoneally.

all of which showed this interaction. Thus the behaviour disrupting effect of mescaline is markedly potentiated following the establishment and maintenance of the CER procedure. This is compatible with the hypothesis that the mescaline acts on the central mechanisms mediating "anxiety" or "stress".

An alternative hypothesis would be that the effect is caused by summation of disruption of behaviour by two independent processes because both mescaline (at higher doses) and the CER schedule (at higher shock intensities) may by themselves disrupt behaviour. It is difficult, however, to distinguish between two hypotheses using any behavioural studies where the behavioural dependent variable is influenced in the same direction by both manipulations. Nevertheless the experimental design used here, and these results obtained, offer a way of determining the interaction between mescaline and central adrenergic activity if additional biochemical data are obtained.

### Cell Proliferation during the Development of Stress Erosions in Mouse Stomach

THE surface of the gastric mucosa, which is continually replaced by rapidly proliferating epithelial cells<sup>1</sup>, is prone to erosion under stress. These lesions occur in man<sup>2,3</sup> and are induced in animals by various experimental procedures<sup>4,5</sup>. Stress of short duration decreases the frequency of mitosis in the stomach of the rodent<sup>6</sup>.

We have measured the number of cells incorporating tritiated thymidine and entering into mitosis in the stomach of the mouse during prolonged stress, before and during the development of erosions. Experimental and control groups, each of thirteen male CFW mice weighing 25–30 g, were housed in individual cages for one week. After this period, each mouse in the experimental group was restrained at midnight in a wire mesh apparatus<sup>7</sup>, and mice were deprived of food and water. Beginning 12 h later, at intervals of 1–3 h two mice, one under stress and one control, were injected with tritiated thymidine, (25  $\mu$ Ci/mouse, specific activity 6.7 Ci/mmole). All animals were killed 1 h after injection, so the first mouse killed in the experimental group had been under stress for 13 h and the last mouse for 42 h.

Stomachs were removed from all animals, opened along the greater curvature, placed on a cork board, and sectioned through the mid-portion of the gastric body. The specimens were fixed in neutral formalin, embedded in paraffin and sectioned at 3  $\mu$  with tissues oriented to pass longitudinally through the columns of the gastric pit. Microautoradiographs were prepared by dipping the sections in 'NTB' liquid emulsion (Kodak). Slides were then exposed for two months in darkness, in a sealed dry box, developed with Kodak 'D'19, and stained with haematoxylin and eosin. Additional slides were prepared with periodic acid-Schiff (PAS) stain.

Histological examination of gastric mucosa under light microscopy after stress caused by restraint revealed scattered focal areas containing moderate vacuolization of cytoplasm in epithelial cells and slight to moderate decrease in PAS-positive mucopolysaccharide. Desquamation of surface cells was increased, and in a few areas early collapse of the mucosa was seen, the cells having an

abnormal eosinophilic cytoplasm with pyknotic nuclei; there was no oedema, inflammatory exudate or necrosis.

Counts of metaphase figures, cells labelled with tritiated thymidine and unlabelled cells were made. Background levels averaged one grain in an area occupied by twenty nuclei in these sections. In each specimen 4,000 epithelial cells were counted randomly. Eleven of the thirteen animals which had been under stress had reduced mitoses compared with the controls, and twelve of the thirteen had reductions in labelled cells. Table 1 compares the group averages of controls and all animals under stress from 13–42 h, and gives the counts made of cells in metaphase and cells labelled with tritiated thymidine, together with standard errors of the group averages. The level of  $P$  for differences between control and experimental groups indicates that the frequencies of mitoses and labelled cells were significantly decreased in the stress group. These decreases were in areas of mucosa containing no histological changes, and were pronounced in areas showing the histological alterations mentioned earlier. Despite cell damage and loss therefore, during the development of the erosions the rate of replacement of epithelial cells was significantly lower than that of the non-stressed controls.

Table 1. COUNTS OF MITOSES AND LABELLED CELLS

Group averages and standard errors of counts made on cells in metaphase and cells labelled with tritiated thymidine					
No.	Average count/ 1,000 ( $\pm$ S.E.)	Stress	$t$ ratio and associated $P$ level for difference between control and stress groups		
Stomach					
Mitosis	13	4.1 $\pm$ 0.39	2.7 $\pm$ 0.39	$t_{24} = 2.536$	0.02 $> P > 0.01$
Labelled cells	13	96.0 $\pm$ 7.74	53.9 $\pm$ 14.9	$t_{24} = 2.506$	0.02 $> P > 0.01$

Four thousand cells counted in each stomach specimen of the thirteen animals in each group. The counts for each group were examined for distribution properties and these were found to be consistent with the normal distribution.

Tritiated L-leucine-4,5 (specific activity 5 c./mmole, 100  $\mu$ C./mouse) was also injected intraperitoneally into two additional groups of stressed and control animals maintained under the same conditions; animals were again killed 1 h after injection. Using microautoradiography, the comparative rates of protein synthesis in intestinal epithelial cells were estimated\*. The results showed active incorporation of leucine into all cell types. Grain counts over cytoplasm indicated equivalent amounts of leucine incorporated in both groups (epithelial cells 12.9 and 11.7 grains/cell, respectively, in control and experimental mucosa; parietal cells 44.2 and 40.9 grains; zymogen cells 44.4 and 45.8 grains, always with  $P > 0.5$ ). Throughout the mucosa, epithelial cells showing histological abnormalities were well labelled with leucine, as seen after early radiation damage\*.

This investigation was supported by the US Public Health Service, National Institute of Arthritis and Metabolic Diseases. We thank Dr George Teebor for assistance in interpreting the pathological abnormalities.

## Effect of Calcium and Phosphates on Gastrointestinal Absorption of Strontium and Calcium in Newborn Rats

An increase in the calcium and phosphate in the diet has been shown to cause decreased absorption of strontium from the gastrointestinal tract in growing rats<sup>1-4</sup>. The same effect of phosphates on strontium absorption was also observed in pregnant female rats and in their litters, suggesting that an increased phosphate intake into the nursing mother provides an effective means of decreasing the uptake of radioactive strontium in her litter<sup>5</sup>. This effect could be caused by either the action of the higher phosphate content in mothers' milk on calcium and strontium absorption from the gastrointestinal tract in newborn rats, or by a decreased ratio of strontium to calcium in the milk, caused by the influence of phosphates on calcium and strontium metabolism in the nursing mother. We have tried to clarify this point.

Our experiments were carried out on rats 5 days old which were artificially fed on cows' milk and on cows' milk to which  $\text{KH}_2\text{PO}_4$  or  $\text{CaCl}_2$  and  $\text{KH}_2\text{PO}_4$  had been added to increase dietary phosphorus only (Table 1) or

Table 1. INFLUENCE OF PHOSPHATE ADDITIVES TO MILK IN ARTIFICIALLY FED RATS ON CALCIUM AND STRONTIUM ABSORPTION FROM THE GASTROINTESTINAL TRACT IN 5-DAY-OLD ANIMALS

Milk (mg/100 ml.)		No. of rats	Retention in carcass % oral dose		
P	Ca		Strontium-85	Calcium-45	Strontium-85/ Calcium-45
45	140	52	82.32 $\pm$ 1.47	81.93 $\pm$ 1.46	1.01 $\pm$ 0.005
230	140	68	82.35 $\pm$ 1.27	82.81 $\pm$ 1.55	1.00 $\pm$ 0.072
500	140	59	82.84 $\pm$ 1.46	84.52 $\pm$ 1.67	0.97 $\pm$ 0.014

Strontium-85, calcium-45 and  $\text{KH}_2\text{PO}_4$  were added to cows' milk, which was fed to rats by means of a dropper; each rat received an average of twenty-five drops (0.5 ml.) during 12 h.

Table 2. INFLUENCE OF CALCIUM AND PHOSPHATE ADDITIVES TO MILK IN ARTIFICIALLY FED RATS ON CALCIUM-45 AND STRONTIUM-85 ABSORPTION FROM THE GASTROINTESTINAL TRACT IN 5-DAY-OLD ANIMALS

Milk (mg/100 ml.)		No. of rats	Retention in carcass % oral dose		
P	Ca		Strontium-85	Calcium-45	Strontium-85/ Calcium-45
95	140	30	86.55 $\pm$ 1.16	85.87 $\pm$ 1.18	1.00 $\pm$ 0.006
230	400	30	76.05 $\pm$ 2.29	74.49 $\pm$ 2.13	1.02 $\pm$ 0.010
500	1,000	37	65.85 $\pm$ 2.36	67.00 $\pm$ 2.61	0.98 $\pm$ 0.009

Strontium-45, calcium-45,  $\text{CaCl}_2$  and  $\text{KH}_2\text{PO}_4$  were added to cows' milk, which was fed to rats by means of a dropper during 12 h; each rat received an average of twenty-five drops (0.5 ml.).

to increase both the calcium and phosphate intake (Table 2). Tracer amounts of carrier free calcium-45 and strontium-85 were added to the milk.

The average concentration of calcium and phosphate in cows' milk used in these experiments was 140 and 95 mg/100 ml., respectively, as analysed by standard methods<sup>6,7</sup>. By adjusting the concentration of calcium and phosphate in the milk to 400 mg and 230 mg/100 ml., respectively, the normal concentration of calcium and phosphorus in rats' milk was found<sup>8</sup>. The milk with the highest content of calcium and phosphate (1,000 mg of calcium and 500 mg of phosphate/100 ml.) corresponds to the calcium and phosphate concentration in the diet of a normal adult rat. The baby rats were fed by means of a dropper for a period of 12 h, each rat receiving 25 "standard" drops equivalent to 0.5 ml. They were returned to their nursing mothers overnight and killed 12 h later. The content of strontium-85 and calcium-45 in the carcass was determined after removal of the gastrointestinal tract. The results are presented as percentage of the oral dose retained in the carcass.

Increase in the phosphate content of the milk had no effect on the retention of either strontium or calcium in 5-day-old rats as shown in Table 1. A simultaneous increase of both calcium and phosphate in the diet caused a small but statistically significant reduction in the absorption of radioactive strontium and calcium from the gastrointestinal tract (Table 2). The absorption of calcium-45 was only some 20 per cent less in rats fed on milk with a seven times greater calcium content (1,000 mg/100 ml.) and so the total absorption of calcium was some

five to six times greater in this group of animals. The ratio of strontium-85:calcium-45 in the carcass, if corrected for the calcium content of the diet, would be seven times lower in the same group of animals.

These results confirm the earlier findings of a relatively high absorption of strontium and calcium from the gastrointestinal tract in young babies<sup>9</sup> and very young animals of other species<sup>10</sup>.

Despite this high absorption efficiency and almost complete lack of discrimination against strontium in animals of this age, an increased content of calcium and phosphate in the milk seems to influence strontium and calcium absorption in the gut.

These experiments, however, indicate that the much greater reduction of the retention of radioactive strontium in baby rats observed in our previous experiment<sup>9</sup> was caused by the decreased ratio of strontium to calcium in mothers' milk caused by the increased content of phosphate in the diet of the mother.

The possibility of influencing the absorption of strontium from the gastrointestinal tract of the newborn rat is still being investigated.

### Correlation between Kinetically Defined Calcium Compartments and Contractile Response in Rabbit Atrium

THE importance of calcium ions in the contraction mechanism of skeletal and cardiac muscle has been established on the basis of previous work<sup>1-15</sup>. Calcium seems to be stored in the sarcoplasmic reticulum and plays a critical part in coupling excitation with contraction when released into the sarcoplasm of these tissues after depolarization of the membrane. The exact way in which calcium performs this function is not clear, and, furthermore, calcium in cardiac tissue is divided into at least two components by kinetic studies with calcium-45 (refs. 16-19). This communication presents evidence for the applicability of kinetic analysis to the contraction process in cardiac tissue.

Left atria removed from freshly dissected rabbit hearts were inflated with a gas mixture containing 95 per cent oxygen and 5 per cent carbon dioxide. They were depleted of calcium by soaking in a Krebs-Henseleit solution containing 0.2 mmolar calcium for 2 h and then treated in one of two ways; either soaked for 3 min (group 1a) or 2 h (group 2a) in a Krebs-Henseleit solution containing 5 mmolar calcium chloride. When the atria are returned to a low calcium solution (0.2 mmolar) and stimulated

electrically at a frequency of once a min, an initial rapid decline in tension is noted in both groups. But only the atria of group 2a show a slow linear decline in tension, with a half-time approximating 60 min (Fig. 1). Apparently, initial decline in tension in this experiment results from release of calcium from superficial binding sites, whereas the continuous linear response is caused by a release of a calcium moiety more firmly bound and stored within cellular compartments.

To corroborate kinetic analysis with results of the twitch-tension study, a time course of calcium loss from the tissue after soaking for short and long periods in isotopic calcium was determined. The atria so employed were also depleted of calcium and then soaked for either 3 min (group 1b) or 2 h (group 2b) in a Krebs-Henseleit solution containing calcium-45. Washout in successive changes of non-isotopic Krebs-Henseleit solution followed.

The efflux of calcium-45 occurs rapidly in group 1b while the half-time of desaturation of group 2b is about 90 min (Fig. 2). Thus the time course of loss of tension in the twitch-tension studies can be explained on the basis of a two compartment (superficial and intracellular) concept of calcium storage. Furthermore, Fig. 2 shows that, when the linear portion of curve 2b is extrapolated to zero time and subtracted from the original curve, a second curve which corresponds to the slope of curve 1b is obtained. The calcium-45 washout curve for group 2b is therefore approximated as the sum of two separate functions: (a) a fast component similar to group 1b representing superficially bound calcium, and (b) a slower one with first order kinetics, representing calcium stored within cell compartments.

There is a correlation between kinetically defined calcium compartments and twitch-tension response in cardiac muscle. Initial rapid loss of contraction in these experiments is caused probably by release of calcium from superficial binding sites, whereas slow linear decrease in tension is an effect of slow release of calcium from the intracellular compartments.

Fig. 1. Comparison of the decline of twitch-tension of rabbit atria previously depleted of calcium and then soaked for either 3 min (●, group 1a) or 2 h (○, group 2a) in a Krebs solution containing 5 mmolar calcium chloride. Electric stimulation was applied at a frequency of once each min in a Krebs solution containing low calcium (0.2 mmolar). Each point is the mean of four experiments. Vertical bars represent standard error of the mean.

Fig. 2. Desaturation curve of calcium-45 for rabbit atria washed out in non-isotopic Krebs solution after soaking in Krebs solution containing tracer amounts of calcium-45 for 3 min (●, group 1b) and for 2 h (○, group 2b). Each point is the mean of five experiments. Vertical bars represent standard error of the mean. △, Curve obtained after linear portion of group 2b curve is extrapolated to zero time and then subtracted from original curve.

## PATHOLOGY

### Effect of Chlordiazepoxide on Stomach Ulcers in Rabbit Induced by Stress

In an earlier communication<sup>1</sup> we reported that premedication with chlordiazepoxide (CDP), a 1,4-benzodiazepine derivative, prevented the eosinopenia caused by emotional stress in rabbits, acting in a manner antagonistic to adrenocorticotrophic hormone (ACTH). Furthermore,

CDP behaves antagonistically towards another hormone involved in stress, namely, antidiuretic hormone<sup>2</sup>. The effect of premedication with CDP on stomach ulcers induced by stress has now been investigated.

Male rabbits weighing 1.5–2.0 kg were used. Emotional stress was applied daily for 21 days as previously described<sup>1</sup> using the method of Colfer *et al.*<sup>3</sup>. Three rabbits received electroshock only and acted as controls. Three rabbits received daily intraperitoneal injections of CDP (50 mg/kg) 30 min before electroshock. Daily blood counts showed that eosinopenia occurred in the control group only. After 21 days the animals were killed and the stomachs examined with a hand lens. Stomachs from the control group all showed extensive congestion, numerous haemorrhages, shedding of the epithelium over large areas and distinct ulceration. Among the experimental group there was slight shedding of epithelium in one rabbit and some congestion in all three, but no haemorrhage and no ulceration.

It thus appears that premedication with CDP affords protection against the effects on the stomach of emotional stress. It is unlikely that gastric acidity played any part in these experiments, because the pH of the stomach contents was the same in both groups. In a separate investigation<sup>4</sup>, it has been shown that premedication with CDP prevents the stomach damage in rats usually caused by the stress of restraint. In other experiments, we have found that stomach ulcers produced by chronic administration of cortisone to rats were not prevented by similar premedication with CDP.

It may be assumed that stomach lesions following emotional stress are caused by adrenocortical hormone released in response to increased concentrations of ACTH in the blood. It seems reasonable to infer from the present investigations that the antagonism between CDP and ACTH prevents the release of adrenocortical hormones in amounts sufficient to damage the stomach.

### Pyrogen in the Urine of Febrile Patients with Hodgkin's Disease

THE mechanism whereby bacterial infections induce fever has been elucidated in some detail<sup>1,2</sup>. Bacteria and bacterial pyrogens (exogenous pyrogen) interact with polymorphonuclear granulocytes of the host, resulting in release into the circulation of a soluble product of the granulocyte (endogenous pyrogen) which is the proximate cause of the fever through its action on the temperature control centre of the host. Exogenous pyrogen and endogenous pyrogen may be distinguished in several ways, but the most striking difference between their actions is that tolerance to the first develops rapidly, whereas endogenous pyrogen continues to cause fever after a long sequence of daily injections.

Less is known about the mechanisms responsible for fever not associated with bacterial infection. Such fever is frequently seen in patients with Hodgkin's disease. This study was undertaken to determine whether an analogous mechanism (that is a circulating pyrogen of the "endo-

Fig. 1. Rectal temperature of rabbits injected with urine concentrates representing 0.4 per cent of 24 h collections from a febrile patient with Hodgkin's disease and a healthy control.

genous" type) could be demonstrated during febrile episodes in uncontrolled Hodgkin's disease. Initial studies were similar to those described by Snell<sup>3</sup>. Plasma was obtained from febrile patients, stored, and re-infused into the same individuals after remission of Hodgkin's disease had been induced. Although the results of a few experiments of this type were more encouraging than those described by Snell, the same conclusion was reached, namely, that this was not a feasible technique for the study of circulating pyrogens in man. We then investigated the possibility that the presumed pyrogen in Hodgkin's disease might be excreted in urine and might induce fever in a foreign species.

Urine was collected in glassware free of pyrogen in the presence of antibiotics, dialysed and concentrated by ultrafiltration to 10–15 per cent of its original volume. Urine processing was monitored bacteriologically and sterility of the final product was demonstrated before use. Urine concentrates were injected intravenously in volumes of 2–3 ml. (representing 0.03–1.0 per cent of 24 h urine collections) into trained rabbits, known to maintain stable rectal temperatures during 8 h of restraint in the pyrogen laboratory. Temperatures were determined by an electronic thermometer, coupled to sensors in rectal probes. Usually, groups of three animals were used for assay of individual doses of urine concentrate. Controls were injected with concentrates from urine of healthy individuals, collected and processed under similar conditions. These doses of urine concentrate were well tolerated by the rabbits.

Fig. 1 presents data from a representative experiment. Doses of concentrate representing 0.4 per cent of the respective 24 h urine collections from a febrile patient with Hodgkin's disease and a healthy physician were administered to groups of three rabbits. No rise in temperature followed injection of the control material. A prompt monophasic fever with a peak temperature elevation of 2.1° C, however, was induced by the Hodgkin's urine concentrate. This fever persisted throughout the experiment.

Urine concentrates from six of seven patients with uncontrolled Hodgkin's disease and temperatures exceeding 102° F daily regularly induced fever in rabbits. Unequivocal fever followed injection of concentrate representing as little as 0.06 per cent of some 24 h urine collections. Material from two different collections from the seventh patient, in amounts representing up to 1 per cent of the 24 h urine volumes, did not induce fever. Concentrates of urine from four different healthy individuals, injected in amounts representing 0.4–1 per cent of the 24 h

urine volumes, failed to induce fever. Both monophasic and biphasic fevers were induced by pyrogenic urine fractions. The degree of temperature elevation and the shape of the fever curve appeared to reflect, at least in part, individual differences among rabbits as well as characteristics of the material injected; thus the same urine concentrate injected in the same dose might induce monophasic fever in some rabbits and biphasic fever in others.

These urinary pyrogens were compared with two types of exogenous pyrogen in the following experiment. Four groups of three rabbits received daily injections for one month as follows: group 1, typhoid-paratyphoid vaccine, USP, 0.01 ml. daily; group 2, partially purified lipopolysaccharide from *Escherichia coli* 026-B6, 0.3 µg daily; group 3, pyrogenic urine concentrate from a febrile patient with Hodgkin's disease in a daily dose representing 0.063 per cent of a 24 h urine collection; group 4, pyrogenic urine concentrate from another febrile patient in a daily dose representing 0.25 per cent of a 24 h urine collection. These doses were chosen after preliminary testing in other rabbits had shown that they produced comparable febrile responses. Fig. 2 presents temperature curves obtained on different days of the experiment, in groups 2 and 3. The upper panel shows the febrile responses to *E. coli* endotoxin on the first, third and eighth days. A biphasic fever which lasted almost 5 h was observed on the first day. On the third day, the fever was monophasic and lasted a little less than 3 h. By the eighth day, all 3 rabbits were tolerant to this dose of endotoxin; this tolerance was maintained during the remainder of the experiment. The lower panel presents temperature curves for group 3. On the first day, a biphasic fever, almost identical to that obtained in group 2, was observed. On the third day, the fever was monophasic and lasted about 3 h. On the eighth day, the febrile peak was slightly lower and somewhat delayed. The response on the twenty-eighth day of consecutive injections was indistinguishable from that on the eighth day. Fever curves for group 1 were very similar to those shown for the *E. coli* endotoxin; all rabbits became tolerant to the

Fig. 2. Rectal temperature on various days of rabbits receiving daily injections of *E. coli* endotoxin (above) and urine concentrate from a febrile patient with Hodgkin's disease (below).

pyrogenic effects of typhoid-paratyphoid vaccine within 8 days. The curves for group 4 resembled those obtained with the more potent pyrogenic concentrate used for group 3; although a decrease in the duration of the febrile response occurred during the first week of daily injections this material continued to induce fever throughout the month long experiment.

Pyrogenic urine concentrates were then administered to rabbits which had been proved to be completely tolerant to the pyrogenic effects of *E. coli* endotoxin, typhoid-paratyphoid vaccine, or both. Febrile responses were observed in five of six experiments. The maximal temperature elevations were very similar to those obtained in non-tolerant rabbits given the same doses, but the duration of clear cut fever was distinctly shorter. Fig. 3 presents data from a typical experiment. Urine concentrate from patient S.S., in a dose representing 0.13 per cent of a 24 h collection, induced peak temperature elevations of 1.2° C both in non-tolerant rabbits and in animals tolerant to both *E. coli* endotoxin and typhoid-paratyphoid vaccine. A biphasic fever lasting 5 h was observed in the former, however, whereas the latter manifested a shorter, monophasic response. These results are similar to those obtained by Atkins and Huang<sup>4</sup> with administration of endogenous (serum) pyrogen to rabbits tolerant to an exogenous pyrogen.

Fig. 3. Effect of the same dose (0.13 per cent of a 24 h collection) of a pyrogenic urine concentrate from a patient with Hodgkin's disease on temperature of normal and bacterial pyrogen tolerant rabbits. Controls received a urine concentrate representing 1 per cent of a 24 h collection from a healthy individual.

Our inability to induce tolerance to the pyrogenic effect of urine from patients with Hodgkin's disease, and the production of fever by these urine concentrates in rabbits completely tolerant to two bacterial pyrogens, indicate that the material excreted by these patients resembles "endogenous" rather than "exogenous" pyrogen. These results would appear to exclude bacterial pyrogen, whether derived from unrecognized infection in the patients or from contamination during urine processing, as the cause of the febrile responses observed in test animals. We conclude therefore that many febrile patients with uncontrolled Hodgkin's disease excrete in their urine a material which has some of the characteristics of endogenous pyrogen. Such material was not found in urine collected from healthy individuals and tested in equal or greater doses. Work is currently in progress to identify some of the biochemical characteristics of this pyrogen and to determine whether it is specific for Hodgkin's disease or whether it may reflect the presence in the circulation of a final common mediator for the production of various types of fever in man.

This investigation was supported in part by the American Cancer Society.

## MICROBIOLOGY

### Isolation of Half Molecules of DNA from Gram-negative Bacteria

THE isolation of intact DNA of the same size and form as that present in the organism is possible in the case of viruses<sup>1</sup> but presents problems in bacteria and higher organisms, principally as a result of the action of degrading enzymes and mechanical shear. Isolated bacterial DNA usually has a relatively low molecular weight ( $S^{20,w}$  between 11–33)<sup>2,3</sup> except in the cases of *E. coli*<sup>4</sup>, *B. subtilis*<sup>4</sup> ( $S^{20,w}$  of 81) and *H. influenzae*<sup>5</sup> ( $S^{20,w}$  of 94).

We report the results of attempts to minimize the degrading factors in preparations of DNA from Gram-negative bacteria. The organisms used were strains of *Salmonella typhimurium*, *Proteus mirabilis*, *Alcaligenes faecalis*, *Pseudomonas aeruginosa*, *Escherichia coli* and *Shigella flexneri*. Organisms were grown overnight in 4 l. Difco nutrient broth at 37° C and cells were collected by centrifugation in the cold. The yield of about 10 g packed cells was suspended at room temperature in 50 ml. of 0.1 molar *tris*-0.015 molar NaCl buffer, pH 9.0. To this sodium dodecyl-sulphate was added at a final concentration of 1 per cent. With gentle agitation the mixture assumed a jelly like viscous consistency as a result of massive cell lysis. Fifty ml. of a 90 per cent freshly distilled phenol solution<sup>4</sup>, at 55° C, was added to deproteinize the mixture which was shaken at 5 r.p.m. for 20 min and then centrifuged at 3,000*g* for 60 min. The mixture separated into three layers. Between the upper phase and the lower brown phenol fraction a white gel like material consisting chiefly of denatured protein was present. The upper, very viscous, layer was carefully removed by means of a special pipette with an orifice of 5 mm to minimize shearing. The phenol and other interfering substances of low molecular weight were removed by dialysis against a 0.15 molar NaCl-0.015 molar citrate buffer, pH 7.0. Four changes of the buffer at intervals of 4 h were sufficient. The crude DNA was incubated for 1 h at 37° C with 50  $\mu$ g RNase/ml. solution. The mixture was cautiously agitated for 20 min at room temperature after the addition of 0.79 g activated charcoal<sup>6</sup>/ml. of solution. The charcoal was removed by spinning at 10,000*g* for 10 min. The absence of RNA and protein was established by the Smellie and Krotkov method<sup>7</sup> and the Folin-Ciocalteu reaction<sup>8</sup>. The concentration of DNA was determined according to the modified Burton method<sup>9</sup>. Sedimentation velocity centrifugation in the Beckman model *E* analytical centrifuge, using ultra-violet optics, indicated a homogeneous preparation. Sedimentation coefficients were determined in the same apparatus. To minimize shear forces, DNA solutions were placed in the centrifuge cell with a wide bore pipette while one of the quartz windows was removed. All runs were conducted at 9,945 r.p.m. to avoid the anomalous effects observed with large DNA molecules<sup>10</sup>. Films were traced on a Beckman analytical Type R6 microdensitometer. The results are shown in Fig. 1.

Fig. 1. Reciprocal of the sedimentation coefficient as a function of concentration. *S. typhimurium*, *P. mirabilis*, *A. faecalis*, *P. aeruginosa*, *E. coli* and *S. flexneri* are presented by  $\circ$ ,  $\square$ ,  $\triangle$ ,  $\bullet$ ,  $\blacksquare$  and  $\bullet$  respectively.

As can be seen, all results fall almost on the same line which extrapolates to give  $S_{20,w}^0$  equal to 62.5. For the sake of interest, this value is in good agreement with the  $S_{20,w}^0$  of whole DNA molecules from bacteriophages  $T_2$  and  $T_4$  (refs. 2,11,12), which does not necessarily imply that phage DNA occurs in units half the size of bacterial DNA. When the value of 62.5 is compared with that of Massie and Zimm<sup>4</sup> and Berns and Thomas<sup>5</sup>, it is obvious that degradation due to shearing has taken place. The most probable step at which shear degradation could have occurred is the removal of RNA by charcoal.

If the value of 62.5 is assumed to be the  $S_{20,w}^0$  for half molecules, a value of about 83 should be obtained for whole molecules. The value of 83 is in good agreement with the result of Massie and Zimm<sup>4</sup> but not with the value according to Berns and Thomas<sup>5</sup>. When the DNAs for *P. mirabilis* and *E. coli* were subjected to increasing shear forces, the molecules were shear degraded to molecules with  $S_{20,w}^0$  of 45, 31 and 22, respectively. These values correspond then to quarter, eighth and sixteenth molecules.

Taking all these results into consideration it seems that half molecules were isolated with a  $S_{20,w}^0$  of 62.5 and a molecular weight of about 120 million as calculated according to the equation of Crothers and Zimm<sup>11</sup>. Furthermore, it appears that the so-called whole or intact DNA molecules of bacteria have a  $S_{20,w}^0$  of approximately 81 and a molecular weight in the region of 250 million. It is thus hard to avoid concluding that in bacteria the DNA occurs in the organism in an assembly of sub-units of about  $250 \times 10^6$  molecular weight probably held together by protein.

We thank Professor J. N. Coetzee for supplying the strains *S. typhimurium*, *P. mirabilis*, *P. aeruginosa*, *E. coli* and *S. flexneri*.

## Association of AAV-1 with Simian Adenoviruses

THE discovery of small virus particles resembling AAV<sup>1</sup> in preparations of the simian adenoviruses SV<sub>11</sub>, SV<sub>15</sub> and SV<sub>34</sub> (refs. 1-4) suggested that these agents might be widely distributed among the simian adenovirus group. We therefore examined electron microscopic preparations<sup>1</sup> of several recognized simian adenoviruses for the presence of these agents and tested hyperimmune simian adenovirus antisera for the presence of complement-fixing (CF) and precipitating antibodies to AAV-1 (ref. 5), a serotype first isolated from a simian adenovirus stock<sup>1</sup>. In addition, it was of interest to determine whether normal monkey sera contained antibodies to AAV-1 and whether the presence of these antibodies would correlate with the presence of adenovirus antibodies.

A compilation of our results on the correlation between the demonstration of AAV-like particles on one hand and the demonstration of antibodies to AAV-1 in hyperimmune rabbit sera on the other is presented in Table 1. Small particles resembling AAV were found in seven out of sixteen adenovirus preparations examined by electron microscopy. All these adenoviruses had been purified by terminal dilution in rhesus kidney cells in the presence of SV<sub>5</sub> and SV<sub>40</sub> antisera. Thus it does not seem that this method of purification eliminated the small viral particles from these adenovirus stocks. This is interesting in view of the communication of Hoggan *et al.*<sup>6</sup>, who reported that AAV could be eliminated from human adenovirus stocks by limiting dilutions as well as by plating.

\* Less than 2.

† Anti-complementary.

‡ Not tested.

Antibodies to AAV-1 were detected in eight out of fifteen hyperimmune sera examined by the CF test and in four out of fifteen sera examined by the Ouchterlony method (Table 1). Of the seven simian adenoviruses found by electron microscopy to contain AAV-like particles, CF antibodies were demonstrated in four out of seven hyperimmune rabbit sera prepared against these agents (three out of seven were anti-complementary) while only two out of seven of these sera were positive by the Ouchterlony test when AAV-1 was used as antigen. It is interesting that four additional simian adenovirus sera were found to contain CF antibodies to AAV-1, although no AAV-like particles were seen in the simian adenovirus preparations examined by electron microscopy. One of these four sera was also positive by the Ouchterlony test. Finally, one serum, too anti-complementary for significant CF testing, was found to contain precipitating

antibodies for AAV-1. Because the successful demonstration of the small viral particles by electron microscopy would require the presence of approximately  $10^6$  particles/ml. in the original material, it was not surprising to find that although several of the sera reacted by complement fixation and/or Ouchterlony tests with AAV-1, no AAV-like particles were discerned by electron microscopy. Apparently, in these instances there was, none the less, sufficient AAV-1 to act as antigen in stimulating the production of specific antibodies in the inoculated animals.

Several AAV serotypes have been found in human adenovirus stocks<sup>6-8</sup>. Passage of the SV<sub>15</sub> stock reported here (3464) three times with AAV-1 antiserum in African green of LLC-MK<sub>2</sub> cells has failed to eliminate all of the small viral particles, in spite of the demonstration of AAV-1 antibodies in SV<sub>15</sub> (3464) hyperimmune sera. This suggests that this stock was contaminated by at least two AAV serotypes, one of which was type 1. Contamination of human adenovirus stocks by two or more AAV serotypes has been observed<sup>6</sup>, and a type 4 serotype has been isolated from a strain of SV<sub>15</sub> (ref. 4). Attempts are now being made to isolate and identify the second AAV contaminant in SV<sub>15</sub> (3464).

Table 2. DEMONSTRATION OF COMPLEMENT FIXING ANTIBODY TO AAV-1 AND ADENOVIRUS GROUP-SPECIFIC CF ANTIGEN IN NORMAL MONKEY SERA

Serum	No. positive*/No. examined AAV-1	Adenovirus group-specific
Rhesus	7/14	9/14
Grivet	0/12	0/12
Vervet	0/5	2/5
Patas	0/3	0/3

\* Titre equal to or greater than 1:4.

The results of complement fixation tests on a small number of monkey sera collected from our animal quarters are presented in Table 2. Of fourteen rhesus sera examined, nine contained adenovirus group-specific CF antibodies and, of these, seven also had CF antibodies to AAV-1. Complement fixing titres for AAV-1 and adenovirus varied in these animals from 1:4 to 1:32. Although adenovirus CF antibodies were detected in certain grivet and vervet sera (titres varying from 1:4 to 1:128), no AAV-1 antibodies were demonstrated. The three patas sera examined did not contain CF antibodies for either of the two antigens.

While the origin of AAV contaminants in simian and human adenovirus preparations is uncertain, these findings suggest that AAV-1 (and perhaps other serotypes as well) may be a defective, covert agent of rhesus kidney cells the presence of which cannot be detected without the aid of an adenovirus "helper". Thus tests of uninoculated control cultures for the presence of adventitious agents may have to include examination of these cultures after inoculation of a test adenovirus "helper", previously shown to be free of AAV. It is interesting that field isolates of human adenovirus are apparently free of AAV, but many AAV-1 contaminated stocks have been passaged in monkey kidney cells<sup>9</sup>. Failure to find AAV in adenovirus preparations examined by the electron microscope is, obviously, no guarantee of the purity of the stock. Other criteria should also be satisfied such as failure to elicit antibodies to any known AAV serotype on hyperimmunization of a competent animal (for example, rabbit, guinea-pig), or failure to demonstrate any immunofluorescence with known AAV antisera in tissue culture cells infected with the stock adenovirus. Finally, the demonstration of AAV-1 antibodies in rhesus sera and the finding of AAV-1 virus in human adenovirus stocks suggested that it might be fruitful to conduct a survey of human as well as rhesus sera for AAV-1 antibodies. Such a survey has been completed and in a preliminary account it was reported that AAV-1 antibodies were found in nineteen out of ninety-two normal human sera<sup>5</sup>.

### Immunogenicity of an Attenuated Strain of Vaccinia Virus on Rabbits and Monkeys

WE have made a study of a virus preparation which shows some promise as a potentially safer live smallpox vaccine. The virus, called the DI<sub>1</sub> strain, is a highly attenuated mutant of dermovaccinia virus which has been isolated<sup>1</sup> by successive 1 day egg passages of the DIE virus—a strain at present authorized for smallpox vaccination in Japan. The DI<sub>1</sub> strain is characterized by the production of tiny pocks on chicken chorioallantoic membrane and is distinguished from DIE by its reaction to fluorocarbon (unpublished results). DI<sub>1</sub> is not pathogenic for mice, guinea-pigs or rabbits, and produces more interferon when irradiated with ultra-violet light and inoculated onto chick embryo fibroblast cultures<sup>2</sup>. We have studied the pathogenicity of DI<sub>1</sub> in monkeys and the immunogenicity of the strain in rabbits and monkeys.

The immunogenicity of the DI<sub>1</sub> strain in rabbits seems to be poor. In our study, pairs of albino rabbits (2.0–2.5 kg) free from pox virus antibody were inoculated either with DI<sub>1</sub> or with DIE subcutaneously and intradermally, with and without Freund's adjuvant. In all cases the inoculum was obtained from infected chorioallantoic membrane, equal parts inoculated at four consecutive weekly intervals and antibody formation was determined<sup>3,4</sup> 6 weeks after the last injections. Antibody formation was insignificant except with subcutaneous inoculation associated with adjuvant. Pathogenic changes were not observed, and the transient local reddening within 30 h of inoculation was presumably a consequence of a non-specific reaction of the treated site.

Inoculation of monkeys with DI<sub>1</sub> preparations gives markedly different results. In our study, two female cynomolgus monkeys (about 3.5 kg) were inoculated with DI<sub>1</sub> virus and one, a control, with DIE (Table 1). Reactions were observed for 7 days and serum antibody was extracted for 6 weeks after inoculation. It is clear from the results in Table 1 that DI<sub>1</sub> strain is pathogenic to cynomolgus monkeys by dermal inoculation. The reaction was characteristic of dermovaccinia virus but less severe than that due to the original strain DIE, whether the inoculation was carried out by multiple pressure, intradermal injections or scarification. Dermal pulp taken from the scarified lesion of monkey No. 2 7 days after inoculation contained  $3.4 \times 10^6$  pock-forming

Fig. 1. Antibody response of cynomolgus monkeys to the primary inoculation of vaccinia virus, strain DIs or DIE. ○—○, Monkey 1 (DIs); ●—●, monkey 2 (DIs); △—△, monkey 3 (DIE). A, Neutralizing antibody; B, complement-fixing antibody; C, haemagglutination-inhibiting antibody.

units/g, which suggests that the virus had replicated there. The antibody response of the monkeys inoculated with DIs was similar to that inoculated with DIE (Fig. 1) and roughly proportional to the dose of virus administered. Neutralizing antibody was more or less constant after the second week, but complement-fixing and haemagglutination-inhibiting antibodies decreased after that time.

These results demonstrate that even though the DIs strain is remarkably non-pathogenic in certain experimental animals and cell cultures, the strain is pathogenic in cynomolgus monkeys and gives an immunity which is comparable with that provided by the original strain DIE. Our data suggest but do not substantiate the possibility

that DIs is less pathogenic in monkeys than DIE. The possibility that DIs may be a strain of variola virus such as alastrim, suggested by the characteristic host range which is at present confined to chick embryo and monkey, can be excluded because DIs does not form hyperplastic foci in the HeLa monolayers<sup>1,5</sup>.

Because of the serious complications of smallpox vaccination with live vaccinia virus, which is pathogenic for several species of animals, several workers are seeking a different procedure using either inactivated or attenuated virus. The DIs strain, which has not yet been tested in humans, is a promising candidate for a safer live smallpox vaccine, for our experiments with laboratory animals show that the virus is highly attenuated but that it is potentially immunogenic in at least one species of primates.

We thank Mr Toshihiko Komatsu for veterinary help in the monkey experiment.

## BIOCHEMISTRY

### Inhibition of RNA Polymerase by Histones

*In vitro* nucleohistones are known to be less efficient templates for RNA polymerase than free DNA<sup>1-3</sup>, but there has been some disagreement as to whether this is due to a real inhibition of RNA synthesis by histones or to their aggregation into precipitates which the reagents cannot penetrate<sup>4</sup>. Sonnenberg and Zubay<sup>5</sup> supported the second suggestion by showing that ultrasonication of nucleohistone which was initially inactive as a template for RNA synthesis caused an increase in activity to about one-third that of free DNA, and Roy and Zubay<sup>6</sup> have recently made similar observations using a mammalian polymerase. Bonner and Huang<sup>7</sup>, however, have repeated their claim that it is possible to prepare soluble nucleohistones which show the inhibition by histones.

In an attempt to resolve this, we have compared the decrease in template activity caused by histones and the precipitation of DNA under similar conditions.

*Escherichia coli* RNA polymerase (fraction 4) was prepared by the method of Chamberlin and Berg<sup>8</sup> and DNA and whole histone were prepared from calf thymus<sup>9,10</sup>. The template activity was measured at two concentrations of DNA. At the higher concentration, which was close to the quantity required to saturate the enzyme, the ratio of histone to DNA was varied between 0.04 and 0.4, and at the lower concentration between 0.2 and 2.0. The reaction mixtures, which contained 10 µg or 50 µg DNA, histone as indicated, 1 mg bovine plasma albumin, 200 µmoles each of ATP, CTP, GTP and UTP, 0.2 µc. tritiated UTP (Schwarz) and 40 µg RNA polymerase in 0.5 ml. 0.01 molar magnesium chloride, 0.01 molar *tris*-HCl (pH 7.9), 0.002 molar β-mercaptoethanol and 0.0001 molar EDTA, were incubated for 10 min at 37° C and assayed essentially as described by Barr and Butler<sup>11</sup>: incorporation in the absence of primer was subtracted. The same solvent was used for the precipitation experi-

ments except for the omission of  $\beta$ -mercaptoethanol and the four nucleotide triphosphates, all of which would interfere with the estimation of DNA by its optical density at 260 m $\mu$ . The precipitation of DNA (40  $\mu$ g/ml.) was measured after centrifugation at 2,000g for 30 min.

The reduction in template activity is by no means parallel with the amount of DNA precipitated, as Fig. 1 clearly shows. We conclude that histone causes a real decrease in the template activity.

Table 1. EFFECT OF ULTRASONICATION ON THE TEMPLATE ACTIVITY AND SOLUBILITY OF CALF THYMUS NUCLEOHISTONE

Primer	Sonication time (min)	Incorporation of UMP ( $\mu$ moles)	Solubility of nucleohistone (percentage of whole)

"	1	23.8	0.04
"	2	20.2	0.06
"	3	15.6	—
"	4	17.5	0.08

Calf thymus nucleohistone prepared by the method of Zubay and Doty<sup>17</sup> was treated with ultrasonication for the periods shown, using an MSE-Mullard 60 W ultrasonic drill: template activity and solubility were measured as described in the text.

Experiments were also carried out in which native nucleohistone was ultrasonicated for varying times. After a short period of sonication there was an increase in template activity but no corresponding increase in solubility (Table 1). The template activity decreased somewhat with the longer periods of sonication and the solubility increased only slightly. The results suggest that once the larger particles are broken further sonication in the conditions used has little effect. We did not use longer periods or more intense sonication, because it is well known that DNA may be degraded by such treatment<sup>12</sup>. It is possible that the increases of activity observed in these experiments and those of Sonnenberg and Zubay<sup>5</sup> are due to the loss of small amounts of histone, especially near the ends of the DNA fibres.

The solubility of nucleohistones in our conditions is very low. Like Sonnenberg and Zubay<sup>5</sup> we have been unable to prepare native "soluble" nucleohistones from calf thymus by the methods described by Bonner and Huang<sup>7</sup>.

The conclusion to be drawn is that the inhibition of RNA polymerase by histones is not related to the solubility as estimated by the criterion which we have chosen. This result, like those obtained with rather different experi-

mental approaches<sup>13-15</sup>, is in accord with the hypothesis that histones are true gene-repressors<sup>16</sup>.

### Incorporation of <sup>14</sup>C-Choline and Tritiated Inositol into Rat Adipose Tissue Phospholipid *in vitro*

PHOSPHATIDIC acid is known to be the only labelled phospholipid which is produced in significant amounts in rat white adipose tissue *in vitro*<sup>1</sup> from 1-<sup>14</sup>C-palmitate, 1-<sup>14</sup>C- or <sup>32</sup>P-glycerophosphate. Steinberg *et al.*<sup>2</sup>, on the other hand, reported that a certain amount of the radioactivity (9-25 per cent) of the total phospholipid, after incubation of adipose tissue homogenates with 1-<sup>14</sup>C-palmitate, was not in the phosphatidic acid fraction. We have investigated the problem of phospholipid biosynthesis in rat adipose tissue and have shown that, together with phosphatidic acid, phosphatidylcholine and monophosphoinositide are probably formed<sup>3</sup>.

In this communication, we present evidence to show that phosphatidylcholine and monophosphoinositide are synthesized *in vitro* in the white adipose tissue of rats from labelled 1,2-<sup>14</sup>C-choline and tritiated inositol, respectively, as precursors.

As shown in Table 1, phosphatidylcholine is formed in white adipose tissue from radioactive choline, but at a very low rate. Weak incorporation into the same lipid has also been obtained from labelled phosphorylcholine incubated under similar experimental conditions.

Inositol is also utilized by adipose tissue for phospholipid biosynthesis (see Table 2). Uptake of inositol into monophosphoinositide is even lower than that of choline into phosphatidylcholine and has been related in these experiments to the phosphorus content of the total phospholipid extract because the quantity of monophosphoinositide detected in the adipose tissue was too low to be reliable. Synthesis of diphosphoinositide or triphosphoinositide from labelled inositol has never been observed when these two phosphatides were properly extracted,

neither has phospholipid formation been detected *in vitro* from either ethanolamine, phosphorylethanolamine or serine under various experimental conditions.

Phosphatidylcholine and monophosphoinositide have been identified by comparison of the radioactive material with authentic reference samples on thin-layer chromatograms and by analyses of the water-soluble phosphorylated products obtained after mild hydrolysis<sup>8</sup> of pooled spots of the phospholipid synthesized from several chromatograms. Glycerolphosphorylethanolamine and glycerolphosphorylinositol were the only labelled products which could be detected and which retained all of the original radioactivity of the parent phospholipid.

Thus our results and those of previous workers<sup>1-3</sup> indicate that phosphatidic acid takes up 10-12 per cent of the <sup>32</sup>P-glycerophosphate radioactivity after 30 min of incubation with rat adipose tissue, while phosphatidylcholine and monophosphoinositide take up at the most 0.5-1 per cent of the radioactivity from labelled choline and inositol, respectively. These findings must be interpreted with some caution, however, because for each phospholipid the nature of the precursor and the composition of the incubation system are different. Low activities of the enzyme systems concerned with the synthesis of phosphorylethanolamine, cytidine-diphosphatidylglyceride and cytidine-diphosphate-choline, which are biological intermediates of the corresponding phospholipid moieties, may explain the weak incorporation of the label into phosphatidylcholine and monophosphoinositide.

Experimental evidence has been reported recently<sup>9,10</sup> which shows that rat adipose tissue phospholipid may be formed *in vitro* from <sup>32</sup>P-orthophosphate as a precursor. Detectable synthesis has been observed for phosphatidyl-inositol, phosphatidylcholine, phosphatidic acid, lyso-phosphatidylcholine and possibly phosphatidylglycerol. Because of the different nature of the precursors the results cannot, however, be strictly compared with those reported here.

4	90	4.5

The homogenates (400 mg of wet weight of tissue), prepared as "defatted homogenates"<sup>11</sup>, were incubated in a final volume of 3 ml. in the following incubation mixture: Krebs-Ringer bicarbonate (equilibrated with 95 per cent O<sub>2</sub> and 5 per cent CO<sub>2</sub>) buffer, pH 7.4; glucose, 10 mmolar; MgCl<sub>2</sub>, 12 mmolar; CTP, 2 mmolar; ATP, 4 mmolar; Na<sub>2</sub>HPO<sub>4</sub>-NaH<sub>2</sub>PO<sub>4</sub>, pH 7.4, 10 mmolar; cysteine, 12 mmolar; Na malate, 2.5 mmolar; 1,2-<sup>14</sup>C-choline chloride, 1 mmolar (6  $\mu$ Ci). Temperature, 37° C. Incubation in air.

Phospholipid was extracted and washed after incubation according to standard procedures<sup>12</sup>. Phosphatidylcholine was revealed by autoradiography of silica gel G thin-layer chromatograms developed in chloroform, methanol, 35 per cent aqueous ammonia (14:6:1 vol.), and identified by comparison with an authentic reference sample. The radioactivity was determined by liquid scintillation of the phosphatidylcholine scraped from the plate<sup>13</sup>, and accordingly corrected for quenching. The phosphorus of the phosphatidylcholine spot was estimated by a micro-scale modification of the method of Strickland *et al.*<sup>14</sup>. The results are expressed as nc. labelled choline/ $\mu$ g of phosphatidylcholine P.

Table 2. PHOSPHATIDYLINOSITOL BIOSYNTHESIS FROM TRITIATED-INOSITOL BY RAT EPIDIDYMAL FAT PADS *in vitro*

Experiment	Time (min)	C.p.m. tritiated-inositol incorporated/ $\mu$ g of P
1	30	505
2	30	461
3	90	601

The homogenates (400 mg of fresh weight of tissue) prepared as described in Table 1, were incubated in a final volume of 3 ml. in the following incubation mixture: *tris* buffer, pH 7.4, 50 mmolar; potassium phosphate, pH 7.4, 10 mmolar; MgCl<sub>2</sub>, 14 mmolar; CTP, 1 mmolar; ATP, 1 mmolar; glucose, 10 mmolar; NAD, 1 mmolar; <sup>3</sup>H-inositol, 0.5 mmolar (3  $\times$  10<sup>6</sup> c.p.m.). Incubation in air at 37° C.

The phospholipid material was extracted with chloroform, methanol (1:1 vol.), and the phospholipids then separated on 'Whatman No. 1' formaldehyde treated paper<sup>15</sup> using, as developing solvent, the upper phase of a mixture of butanol, acetic acid, water and diethyl ether (20:5:25:6, v/v/v/v). The radioactivity of the separated and identified monophosphoinositide (*R<sub>F</sub>* = 0.47) was determined as reported in Table 1. Phosphorus of the total phospholipid extract estimated as described in Table 1. The results are expressed as c.p.m. labelled inositol incorporated/ $\mu$ g of total phospholipid P.

Our results on the *in vitro* biosynthesis of phospholipid in the adipose tissue show that these compounds are formed *in situ* from the appropriate precursors, although at a slow rate. These findings imply that phosphatides in the adipose tissue have an important function. The recent work of Morril and Rapport<sup>11</sup> on the determination of the phospholipid content of newborn rat adipose tissue has shown that both the phospholipid concentration and the DNA content rise at the beginning of the lipid deposition, thus indicating that a net synthesis of phospholipid per cell unit takes place during the time of the lipid deposition, at least in the neonatal period.

### Selective Purification of Phosphoserine Peptides by Diagonal Electrophoresis

WHEN a mixture of amino-acids and/or peptides is separated on paper by ionophoresis and a strip containing all of them is sewn to a new sheet of paper and run again by ionophoresis, under the same conditions, in a direction at right angles to the first, the amino-acids or peptides will finally lie in a diagonal line because the mobility in both dimensions is the same. If the compounds are subjected to some chemical reaction before being run for the second time, however, all those with an altered ratio of charge to mass will have a different electrophoretic mobility and so should not appear on the diagonal line. This technique has been used to identify different kinds of peptides, namely, histidine peptides of the active site of phosphoglucomutase<sup>1</sup>, C-terminal peptides of the  $\gamma$  chain of human foetal haemoglobin<sup>2</sup>, and disulphide bridges of chymotrypsinogen A (ref. 3). In these cases the treatments before the second ionophoretic run were, respectively, photo-oxidation, digestion with carboxypeptidase B *in situ* and performic acid oxidation.

I have applied this method to the identification of phosphoserine peptides, which have in the past been studied either by radioactive techniques, in which the phosphate can be labelled, or by running the partial acid hydrolysate of a protein through a 'Dowex 50' column in the acid form<sup>4</sup>. The second method has the disadvantage that it is not specific and that it is not suitable for peptides which include a basic residue, as could be the case for tryptic peptides (which usually have a basic residue as the C-terminal amino-acid). In the case of phosphoglucomutase, for example, when studying the amino-acid sequence around the active site, the peptide obtained by tryptic hydrolysis contains basic residues and is not retained by a 'Dowex 50' column. Furthermore, Flavin<sup>4</sup>, applying his method of separation in acid hydrolysates of ovalbumin, could not find the dipeptide SerP.Ala; he found Glu.SerP.Ala in one experiment and in very low yields, in spite of the fact that his hydrolysis conditions

Fig. 1. Ovalbumin oxidized with performic acid and digested with pepsin in 0.01 normal hydrochloric acid for 17 h at 37° C. Protein concentration 2.5 mg/ml., enzyme-substrate ratio 1 : 100 by weight. Hydrolysate was run at pH 6.5, 53 V/cm for 1 h, the strip was treated with alkaline phosphatase, as described in the text, and run in the second dimension at right angles, under the same conditions. Arrows show peptides which lost the phosphate group and became more basic.

(11 normal hydrochloric acid, 37° C for 3–4 days) would cause minimum inversion of dipeptide sequences. This type of difficulty is overcome by the technique described here which, besides being selective for phosphoserine peptides, possesses all the advantages of sensitivity and speed offered by paper ionophoresis.

The procedure as applied to a protein hydrolysate is as follows. The hydrolysate is first run in one direction at a given pH and then a marker strip is digested with alkaline phosphatase. This treatment releases the phosphate from the serine phosphate peptides and the negative charges of the phosphate are therefore lost, so that when the strip is run in the second dimension those peptides which are affected by the enzyme undergo a change in mobility and do not appear on the diagonal line.

The method has been tested with serine phosphate which is hydrolysed by alkaline phosphatase from *Escherichia coli* into serine and inorganic phosphate. Several samples, each 10 µl. of a 5 mmolar solution of serine phosphate, were applied in bands of 1 cm on strips (3 × 2 cm) of chromatography paper (Whatman No. 1) and carefully wetted with a solution of the enzyme in 0.2 molar ammonium carbonate, pH 8.8. The strips were kept in a damp chamber at room temperature, dried and sewn to a new sheet of chromatography paper. Serine and serine phosphate were identified by their different electrophoretic mobilities after running the samples by high voltage electrophoresis at pH 3.5, 3 kV for 20 min, and staining with ninhydrin. Different concentrations of enzyme and different times of incubation were tried; 0.3 mg/ml.—the concentration which gave total hydrolysis of serine phosphate in 1 h—was selected for further experiments.

The method has been successfully applied to ovalbumin. The protein was first oxidized with performic acid and then digested with different proteolytic enzymes. One sample was digested with trypsin, one with chymotrypsin and one with pepsin. Each digest was treated as described earlier and when the papers were developed with cadmium-ninhydrin reagent<sup>5</sup> the number of peptides which did not

appear on the diagonal was different in each case. Two principal peptides were obtained in the tryptic digest. The chymotryptic digest gave two principal peptides and the peptic (Fig. 1) four. The peptides were purified and their amino-acid analysis showed that they were fairly large (10 to 20 residues). Two of the peptic peptides had a closely related amino-acid composition and seem to be related to the more acidic of the two principal tryptic peptides. They were found to contain the sequence SerP.Ala reported by Flavin<sup>4</sup> and Shaw<sup>6</sup>. This is the sequence which according to Flavin<sup>4</sup> is susceptible to the action of prostatic alkaline phosphatase.

The other principal tryptic peptide obtained seems to be related to a third peptic peptide and to one of the chymotryptic peptides. They probably include the sequence Asp.SerP. Work on the elucidation of the two sequences is now in progress.

### Solubilization of Insoluble Collagens by Rat Liver Lysosomes

AN enzyme or enzyme system which can degrade calf skin collagen soluble in acid at an acid pH is present in the lysosomes of rat liver cells<sup>1–4</sup>. It has also been shown<sup>5–8</sup> that there is a collagenolytic enzyme system in homogenates of rat bone, and that this system, which can convert rat bone collagen to a soluble form, is localized in sub-cellular particles with some of the properties of lysosomes<sup>6,7</sup>. Experiments with radioactively labelled rat bone collagen<sup>8</sup> suggested that this material is not made appreciably soluble by treatment with large granule fractions from homogenates of kidney, brain, leucocytes and liver at pH 7.4. In this report, the effect of rat liver lysosomes on various insoluble collagens at a variety of pH values is described.

Enzyme activity was released from rat liver lysosomes<sup>9</sup> by five cycles of freezing at –60° C and thawing at 37° C, and the mixture was clarified by centrifuging at 100,000g for 30 min. Collagen fibrils isolated by the Nishihara procedure<sup>10</sup> from the Achilles tendons of ox and aged human and from aged human thigh skin were used as substrate. In addition, rat tail tendons which had been exhaustively extracted with cold 0.5 molar acetic acid were used. The course of the reaction was followed by determination of hydroxyproline in the soluble fraction. In practice, 10 mg of insoluble collagen was incubated with a quantity of lysosomal extract containing 0.25 mg protein for 18 h in 0.2 molar acetate buffer. At each pH collagen was also incubated without enzyme. Hydroxyproline was determined<sup>11</sup> after the removal of undissolved collagen by centrifugation at 0° C for 30 min at 120,000g and hydrolysis with 6 normal hydrochloric acid at 103° C for 20 h. For comparison, collagen was also incubated with 1 mg of crystalline pepsin.

The degradation caused by lysosomes varies from one kind of collagen to another (Table 1). Insoluble rat tail tendon collagen, in many ways an atypical collagen, is most easily solubilized. At the other extreme, collagen from aged human tendon is not affected. It may be significant that the least affected collagens are those which are reported to embody the greatest degree of cross-linkage (ref. 12 and F. S. Steven, personal communication).

Table 1. EFFECT OF LYSOSOMES AND PEPSIN ON VARIOUS COLLAGEN PREPARATIONS AT DIFFERING TEMPERATURES AND pH

5. Human thigh skin Nishihara	"	35	4.0	0.5	0.2

Pepsin conc., 2 mg/ml. Lysosome protein conc., 0.5 mg/ml. Collagen: pepsin, 10:1. Collagen: lysosomal protein, 40:1.

The collagenolytic system is active at pH 4.0. This result contrasts with those of Woods and Nichols<sup>7</sup>, who showed optimum solubilization at pH 6.0 with rat bone homogenates. In their study of rat liver lysosomes these authors determined the solubilization at pH 7.4 (ref. 8). Pepsin has considerably less effect on ox tendon Nishihara collagen than lysosomal extract. At 35° C only 4.2 per cent of the collagen is solubilized by pepsin, whereas 8.0 per cent is solubilized by the lysosomes, in spite of the fact that the total concentration of protein in the crude lysosomal extract is only one quarter of the concentration of crystalline pepsin. To minimize the risk of collagen denaturation, some experiments were performed at both 18° and 35° C. Significant solubilization by lysosomal extracts was observed at 18° C.

These experiments demonstrate conclusively that there is present in rat liver lysosomes an enzyme or enzyme system which degrades undenatured insoluble collagen. The small amount of collagen released may be due to the heterogeneity of the incubation mixture where the available surface area of the substrate is small. A preliminary examination of the solubilized products of ox tendon collagen on polyacrylamide gel electrophoresis<sup>13</sup> suggests that the molecular weight of the larger portion is considerably less than that of the  $\alpha$ -chains of collagen.

Two types of collagenase activity have now been reported in mammals, one having an acid pH optimum<sup>3</sup>, the other showing maximum activity at a pH value which is nearer neutrality<sup>7</sup>. The second enzyme, found chiefly in bone in rats, appears to be similar in its properties to that found in tadpoles<sup>14</sup>. The tadpole enzyme is not stored in the cell but released continuously in tissue culture into the culture medium. It is interesting to suggest that the collagenase acting at neutral pH is essentially extracellular in its action whereas the acidic collagenase can find suitable conditions for action in the phagosome within the cell.

I thank Dr F. S. Steven for his gift of Nishihara collagens and Miss C. Faulkner for technical assistance.

## Sequential Appearance of Phosphoglycerides and Protein in Developing Myelin

MYELINATION is not a sudden event but rather the gradual assembly of various chemical components which appear at the same or different times to form mature myelin. Electron microscopy has shown the gradual morphological development which occurs during myelination<sup>1,2</sup>. The purpose of this study was to inquire into some aspects of the chemical development of myelination of the corpus callosum of the rat, with the use of reliable histochemical techniques.

The brains of sixty rats, 1–16 days after birth, were fixed in various fixatives and embedded in paraffin or cut as frozen sections, as the methods required.

Three methods were used for this study; (a) the gold hydroxamate method for phosphoglycerides; (b) 'Luxol'-fast blue for protein; and (c) osmium tetroxide for unsaturated lipids.

Phosphoglycerides were demonstrated by the gold-hydroxamate method devised by Adams and Davison<sup>3</sup>, modified<sup>4</sup> and remodified<sup>5</sup>; proteins were stained with 'Luxol'-fast blue<sup>6</sup> and the unsaturated lipids were demonstrated with osmium tetroxide<sup>7</sup>. Control sections were also stained by these methods after extraction of lipid with chloroform-methanol (1:3). The phosphoglycerides and unsaturated lipids were thus eliminated whereas the proteinaceous material, stained with 'Luxol'-fast blue (frozen and paraffin section), was not.

Fig. 1. Phosphoglycerides in the "pre-myelin" fibres of the corpus callosum of the developing rat on the first day. C, Cortex; H, hippocampus; cc, corpus callosum. The gold hydroxamate method was used. ( $\times$  c. 100.)

Fig. 2. A protein component of "pre-myelin" fibres in the corpus callosum of a young rat on the eighth day, demonstrated by the 'Luxol'-fast blue technique. ( $\times$  c. 50.)

Fig. 3. Osmophilia of myelin in the fibres of the corpus callosum of a young rat on the twelfth day. ( $\times c. 50$ .)

Sections were also stained with haematoxylin and eosin, silver-iodate, periodic acid-Schiff, myelin and sudan black B.

Phosphoglycerides are present in the "pre-myelin" fibres of the corpus callosum on the first day. 'Luxol'-fast blue demonstrated "pre-myelin" fibres on the eighth day and not before. Koenig<sup>8</sup> and Clasen *et al.*<sup>9</sup> have shown that after extraction of lipid 'Luxol'-fast blue stains a protein related to neurokeratin in myelin and not phospholipids as was previously supposed. Osmophilia demonstrates the presence of unsaturated lipids for the first time on the twelfth day and suggests that the myelin is mature<sup>10</sup>.

This work supports the suggestion that the chemical correlate of myelination is a sequential rather than a simultaneous process.

### Degradation of Human Serum Proteins in the Digestive Tract of Mosquitoes

In the course of investigations aimed at finding the origin of blood ingested by mosquitoes, we took the opportunity of observing the sequence of breakdown of serum proteins in mosquito stomachs. This breakdown may be watched by means of conventional immunological techniques using specific precipitating antisera. We used immunoelectrophoresis and double diffusion in agar gel. The digestive tracts of freshly killed mosquitoes provided the antigen; the tracts were teased apart and placed directly into wells (1.5 mm in diameter) containing agar gel. Antisera prepared against whole human serum and against the following single human proteins, albumin,  $\alpha 2$ -macroglobulin, transferrin, IgM and IgG, have been

used. The results reported here concern only albumin and IgG.

When mosquitoes are killed shortly after ingestion of blood, serum proteins can easily be demonstrated in the stomach by the occurrence of specific precipitation in agar gel. Precipitin reactions, however, become progressively less obvious the longer the time-lapse between feeding and death, and ultimately the reactions become negative. This sequence is likely to indicate digestion of the blood meal. Using *Culex fatigans*, the following observations were made. (a) The rate of disappearance of the different serum proteins varies with the nature of the protein and with the experimental conditions. Sixteen mosquitoes reared in the laboratory were allowed to gorge on several human volunteers and were then kept in a cage. They were killed at various intervals after feeding. Between 24 and 48 h after feeding the albumin could not be detected but IgG continued to react with the specific antiserum for 4 days and sometimes 5 days after feeding. Mosquitoes caught in the wild were similarly allowed to gorge on volunteers but were then left free in a room for 48 h. Eight of these mosquitoes were subsequently captured, killed and dissected. These gave different results: the reactions for albumin were strongly positive but reactions for IgG were negative. The stomach contents were tested from two mosquitoes which had been caught in the wild and fed on human blood in the same house, then kept in a tube in a humid atmosphere for 4 days. The results were similar to those obtained with mosquitoes reared in the laboratory.

(b) When stomach contents were tested with a specific human IgG antiserum, it was found that for all mosquitoes, including those reared in the laboratory, digestion of IgG seems to begin about 5 h after engorgement of blood. At this time a single precipitin line occurring in double diffusion systems is replaced by two lines (Figs. 1 and 2). Because the change from single to multiple lines is reminiscent of the change which occurs when human IgG is exposed to proteolytic enzymes such as papain or trypsin, further double diffusion studies were made to compare the immunological identity of fragments obtained from mosquitoes' stomachs with those produced by enzyme digestion. Pure human IgG was digested with papain after the method of Porter<sup>1</sup> and with trypsin according to Burtin<sup>2</sup>, and the sequence of enzyme digestion followed immunoelectrophoretically. The two fractions obtained by enzyme digestion were then compared in double diffusion systems with the two fractions obtained from the

Fig. 1. Immunoelectrophoretic analysis of a mosquito blood meal developed by a rabbit anti-human IgG serum.

Fig. 2. Agar double diffusion system. M, Mosquito digestive tract; P, human IgG treated with papain; T, human IgG treated with trypsin; AS, anti-human IgG serum (from rabbit).

stomach contents of mosquitoes. The fragments formed during the different digestion process were not identical. Fig. 2 illustrates the broad similarity of the fractions obtained by digestion with papain and trypsin and the obvious dissimilarity of the fractions resulting from digestion of IgG by mosquitoes. This finding suggests that protein cleavage occurring in the stomach of mosquitoes is quite different from that produced by papain or trypsin.

Immunological techniques have been widely used to identify the host on whom mosquitoes feed<sup>3</sup>. Our present findings indicate that the interpretation of the results obtained by such techniques must be made carefully. Environmental conditions could materially influence the rate of protein digestion in mosquitoes and possibly even its sequence. The value of immunological techniques depends largely on the nature of the antiserum used. Our findings indicate that the best results are likely to follow the use of a combination of highly specific antisera rather than the commonly used single polyvalent antiserum.

In our studies the digestion of IgG by the alimentary enzymes of mosquitoes yielded protein fragments which differed from those formed during digestion with papain and trypsin. Further investigation of proteolytic enzymes existing in mosquitoes seems to be merited.

We thank D. Lobe, M. Foy and M. Valade for technical assistance. We also thank Dr I. McGregor for help.

## Deuterium Exchange in Wool

GRAVIMETRIC hydrogen exchange measurements with purified wool confirm an estimate<sup>1</sup> of the amount of crystalline  $\alpha$ -helical material in keratin fibres made from measurements of the intensities of the wide angle X-ray diffraction pattern. Between 90 and 95 per cent of the cross sectional area of wool is occupied by cortical cells and these cells are largely filled with the characteristic keratin matrix-microfibril structure<sup>2</sup>. The deuterium exchange technique may therefore give an approximate estimate of the proportion of crystalline  $\alpha$ -helical material in the matrix-microfibril composite structure.

We believe we can make a clear distinction between two classes of labile hydrogen atoms using the gravimetric technique. The sample of wool contained 0.75 equiv. of labile hydrogen atoms in the side chains and 0.86 equiv. of main chain imide hydrogen atoms, a total of 1.62 equiv. of labile hydrogen atoms/100 g of wool (Table 1). The clear plateaux in Fig. 1 show that in our experiments 1.40 equiv. of labile hydrogen atoms/100 g of wool exchanged with deuterium oxide either instantaneously or at a measurable rate. The remaining 0.22 equiv. exchanged much more slowly. A reasonable interpretation is that all the labile hydrogen atoms in the side chains exchanged instantaneously or at measurable rates, but that parts of the main protein chains were held strongly in stable configurations and so exchanged only very slowly. Thus, in our sample, a fraction 0.22/0.86, or 26 per cent, of the protein chains were in a very stable configuration. We have made experiments with other types of wool and obtained values between 21 and 52

per cent for the fraction of main chain imide hydrogen atoms which exchange only very slowly.

Turner and Woods<sup>1</sup> examined the equatorial X-ray diffraction pattern from Lincoln wool at various extensions up to 100 per cent. Making certain assumptions, they estimated the ratio at each extension of the total amount of crystalline material,  $\alpha$ -helix plus  $\beta$  extended chain, to the original amount of  $\alpha$ -helical material in the unextended fibre. This ratio fell to a minimum, 0.75, at 45 per cent extension. They estimated the amount of non-crystalline material in the unextended fibre and at various extensions from the scattered intensity at 6 Å. During extension this increased to a maximum of 11 per cent above the value at zero extension. From these two results they calculated the fraction of crystalline  $\alpha$ -helical material in unextended Lincoln wool to be about 0.3, and in a merino wool sample 0.24.

We conclude from our deuterium exchange experiments that 26 per cent of the main chain imide hydrogen atoms in merino wool are in very stable regions of the wool protein structure and not freely exposed to solvent. We suggest therefore that these hydrogen atoms are taking part in intramolecular hydrogen bonds between the turns of the helix in the crystalline  $\alpha$ -helical regions of wool<sup>3</sup>. Crystalline  $\alpha$ -helical regions may be so stable that small changes in conformation are almost impossible, exposure of main chain imide hydrogen atoms to the solvent extremely rare, and replacement of imide hydrogen atoms by deuterium therefore very slow<sup>4</sup>.

Fig. 1. The rate of increase in weight of a merino wool sample exposed to deuterium oxide at 0°C (—●—), at 20°C (—×—), and at 37°C (—○—). The rate of deuterium exchange with purified wool was measured with a quartz spring microbalance, as described by Burley *et al.*<sup>5</sup>, modified by surrounding the spring (sensitivity 1,000 cm/g) with a water jacket held at a controlled temperature. The spring chamber can be evacuated by means of a mercury diffusion pump protected by liquid nitrogen traps and backed by a rotary pump, which gave a vacuum better than 10<sup>-4</sup> mm mercury. In the exchange experiments at 37°C a sample of purified wool weighing 20–30 mg was hung on the quartz spring. The spring tube was evacuated for 24 h. Because there was no measurable change in weight after 12 h the sample was assumed to be completely dry. The spring tube was isolated from the pumps, and deuterium oxide (99.97 per cent, Norsk-Hydro) was carefully distilled into the tube. It condensed on the wool sample. Exchange was allowed to occur for 1 h and then the tube was evacuated for 24 h. The new dry weight of the sample was noted, and then it was exposed again for 1 h to deuterium oxide, and dried as before. The procedure was repeated in six stages until the wool had been exposed to deuterium oxide for a cumulative time of 24 h. In the experiments at 20°C a new sample of wool was first dried for 24 h at 37°C, then the water jacket was brought to 20°C before the deuterium oxide was admitted to the spring tube. After each period of exchange the tube was evacuated at 20°C for 1 h and then at 37°C for 23 h. In the exchange experiments at 0°C, exchange and the first hour of drying were carried out at 0°C. Drying was completed at 37°C for 23 h. In one experiment a sample was exposed to deuterium oxide for 108 h at 20°C. There was no detectable difference between the dry weight after exposure for 24 h and 108 h.

Table 1. AMINO-ACID ANALYSIS OF SOUTH AFRICAN MERINO WOOL

	mmoles/g	Hydrogen atoms attached to nitrogen or oxygen atoms equiv./100 g	
		Imide	Side chain
Alanine	0.462	0.0462	—
Arginine	0.608	0.0608	0.2432

Totals:	—	0.863	0.753

\* 0.0644 is the sum of the values for aspartic and glutamic acids minus half the value for amide groups.

The wool was purified as follows. The tips of the fibres were removed, and the wool was extracted with ether in a Soxhlet apparatus. Burrs and vegetable contaminants were removed by hand, and the wool was rinsed several times in cold ethanol and several times in distilled water. It was carefully dried between filter papers and then in air at room temperature. The dry weight of about 25 mg of purified wool was accurately measured, before deuterium exchange, with the quartz spring microbalance. After the exchange experiments it was placed in a phial and 1 ml. 5.7 normal hydrochloric acid/10 mg of wool was added. Dissolved air was removed from the hydrochloric acid by repeated freezing and thawing. Then the phial was sealed under vacuum and the wool hydrolysed for 24 h at 105° C. In parallel experiments samples were hydrolysed for 48 and 72 h. Amino-acid analyses were carried out with a Technicon analyser. Peak areas were calibrated with Technicon standard amino-acids and standard norleucine. Hydrolysis of wool for three different times allowed us to correct for slow decomposition of serine, threonine and cystine, and the corrected analysis is given in the first column. Amide groups were estimated by the method of Corfield and Robson<sup>6</sup> and tryptophan by the method of Graham and Statham<sup>7</sup>. Fletcher, Robson and Todd<sup>8</sup> showed that the cysteine content of wool is about 0.003 equiv./100 g, which is negligible in our experiments. In 12 analyses of different wool samples, the sum of the weights of the component amino-acid residues, after correction for decomposition of serine, threonine and cystine during hydrolysis, was always within 1.5 per cent of the weight of wool contained in the volume of hydrolysate applied to the analyser column. This indicates the accuracy of the analyses and shows that not more than 1.5 per cent of wool is non-protein material, for example lipid or nucleic acid.

This suggestion is supported by an experiment in which a sample of merino wool was reduced overnight at 4° C in 0.2 molar thioglycolic acid, 0.1 molar disodium hydrogen phosphate adjusted to pH 10.5. About half the protein dissolved from the fibres in these conditions. The fibrous residue was re-oxidized by immersing it in 0.45 normal magnesium chloride, 0.15 normal potassium phosphate adjusted to pH 7.0, and bubbling air through the buffer for 24 h. The re-oxidized fibres were rinsed in distilled water. They did not show any sharp wide angle X-ray diffraction pattern: the protein chains appeared to be completely disordered by this treatment. An amino-acid analysis showed 1.57 equiv. of labile hydrogen atoms/100 g of disordered fibres. In an exchange experiment, all the labile hydrogen atoms were replaced by deuterium after 24 h at 37° C.

Bendit<sup>5</sup> has recorded the changes which take place in the infra-red spectrum of a longitudinal section of horse-hair exposed to deuterium oxide, when the radiation is polarized parallel or perpendicular to the fibre axis. There is evidence that in 16 h at 35° C some exchange of imide hydrogen by deuterium occurs in  $\alpha$ -helices. It is possible that these may be single helices approximately aligned with the fibre axis, and not part of the crystallites. There is also evidence that exchange of the labile hydrogen atoms in arginine side chains may not be instantaneous at 35° C. If the proportion of imide groups in crystalline  $\alpha$ -helices which exchange in several hours at 35° C, and the proportion of arginine side chains which do not exchange, are not negligible, then the agreement we found between X-ray and gravimetric deuterium exchange measurements of the proportion of crystalline  $\alpha$ -helix in wool may be fortuitous. Bendit points out, however, that it is difficult to make the infra-red method quantitative and to be certain of the assignment of wavelengths.

### Concentrations of RNA in the Brain during Oestrus in the Deermouse

THERE has recently been extensive research into the role of nucleic acids in biological systems, and the part played by RNA in protein synthesis has now been established as has that by oestrogen in protein synthesis of certain tissues.

With this in mind, we have analysed the hypothalamus, amygdala and frontal cortex of adult female deermice (*Peromyscus maniculatus bairdii*) for total RNA content during dioestrous, pro-oestrous and oestrous stages of the oestrous cycle. Vaginal smears were made daily to determine the stage of oestrus. As soon as the stage of the oestrous cycle was established, the mice were killed by decapitation and their brains quickly removed; the hypothalamus, amygdala and frontal cortex were dissected out, frozen in acetone-dry ice, and weighed to the nearest 0.1 mg. About eight identical brain areas from deermice in identical stages of the oestrous cycle were pooled to obtain sufficient tissue for each analysis. At each stage of the oestrous cycle, twelve such pools of tissue were made for a total of 288 deermice in the three oestrous stages. The total content of RNA of the different brain areas was determined by the specific extraction procedure for brain tissue<sup>1</sup> and a quantitative estimation of RNA was made<sup>2</sup> using yeast RNA, Type XI (Sigma), as the standard. Data were analysed statistically by means of a standard *t* test and standard deviations were also determined.

The results indicate that total concentrations of RNA in all three areas studied were the same during the dioestrous stage (Table 1). With the onset of pro-oestrus, there was a significant increase ( $P < 0.01$ ) in total RNA in these three areas, ranging from a minimum of 19 per cent in the amygdala to a maximum of 28 per cent in the frontal cortex. With the onset of oestrus no further changes occurred in the RNA content of the hypothalamus and frontal cortex. There was a significant decline ( $P < 0.001$ ) in RNA content, however, in the amygdala.

This is the first attempt to correlate the concentrations of RNA in the brain with different stages of the oestrous cycle, so any attempt to explain the significance of the changes found would be mere conjecture. They may, however, reflect increased RNA turnover and stimulation of protein synthesis as a result of increased production of ovarian oestrogen with the onset of pro-oestrus and oestrus<sup>3-5</sup>. Another possibility is that changes in con-

Table 1. TOTAL CONCENTRATION OF RNA (IN  $\mu$ g/100 MG) IN THE HYPOTHALAMUS, AMYGDALA AND FRONTAL CORTEX DURING THE OESTROUS CYCLE IN THE FEMALE DEERMOUSE (*Peromyscus maniculatus bairdii*) ( $\pm$  S.D.)

Oestrous condition	Hypothalamus	Amygdala	Frontal cortex
Dioestrus	178.1 $\pm$ 9.4	187.4 $\pm$ 10.2	178.5 $\pm$ 5.3
Pro-oestrus	224.2 $\pm$ 4.2	223.2 $\pm$ 3.4	229.5 $\pm$ 8.3
Oestrus	236.3 $\pm$ 6.8	166.7 $\pm$ 7.4	227.0 $\pm$ 5.9

centrations of RNA reflect a differential increase in neural activity associated with the onset of oestrus.

### Mechanism of the Toxic Effects of Hyperbaric Oxygen

THE mechanism of the toxic effects of hyperbaric oxygen has long been a subject of discussion and Haugaard<sup>1</sup> has summarized the evidence in favour of the view that the toxicity is due to oxidation of sulphhydryl groups. More recently, however, Chance *et al.*<sup>2</sup> observed that 11–17 atm. of oxygen selectively inhibit the energy-linked reduction by succinate of nicotinamide-adenine dinucleotide (NAD). Because this inhibition occurs much more rapidly than oxidation of sulphhydryl groups, Chance *et al.* suggested the energy-linked reduction of NAD by succinate as the site of the toxic effects of hyperbaric oxygen. The oxygen pressures used by Chance, however, were much greater than those customarily used therapeutically<sup>3</sup>—that is 3 atm. Because toxicity is also observed at these pressures, it seemed desirable to examine the effects of oxygen at 3 atm. on the energy-linked reduction of NAD by succinate.

In the experiments described here, the reduction of NAD was studied by coupling it to a system which utilizes NADH, namely the synthesis of glutamate from  $\alpha$ -oxoglutarate and ammonia<sup>4</sup>. Table 1 shows that oxygen at 3 atm. has no effect on the synthesis of glutamate, even after pre-incubation for 60 min at 25° C. The reaction at 3 atm. of oxygen was carried out in the high-pressure chamber described by Boerema<sup>5</sup>.

A sensitive method of following the state of oxidation-reduction of the nicotinamide nucleotides in rat liver mitochondria is to measure the deamination of glutamate. Papa *et al.*<sup>6</sup> have shown that deamination is slight when the mitochondrial NADP is kept low by the combined action of the energy-linked reduction of NAD by succinate and the nicotinamide nucleotide transhydrogenase. Inhibition of the former by malonate, for example, causes extensive deamination. The amount of ammonia formed after oxidation of glutamate for 60 min was found to be the same with 3 atm. of oxygen as with 0.2 atm.

Thus according to both tests used, oxygen at 3 atm. was found to have no effect on the energy-linked reduction of NAD by succinate in rat liver mitochondria, and so this system does not appear to be the site of the toxic action of oxygen at this pressure.

### Preparation Parameter for Macromolecules

SOME measurable parameter which could characterize the methods of isolation of a natural macromolecule from its source would be useful. Such a parameter, it seems, could be provided by a measure of the polydispersity of the buoyant density of the molecules when in solution and subjected to ultracentrifugation. The parameter of interest is the standard deviation  $\gamma$  of the Gaussian distribution of buoyant densities and can be obtained from centrifugation experiments alone if an empirical relationship between sedimentation coefficient  $s$  and molecular weight  $M$  is known for the material being investigated. In this communication, the theoretical basis for the use of  $\gamma$  is suggested and some preliminary experimental results for various samples of DNA are given.

If a steady density gradient is created within a liquid held in a cell which is itself subject to centrifugal forces and a macromolecular solute be present, then, provided the solute is either homogeneous or has a Gaussian distribution in buoyant density, the variation of concentration of the solute particles with distance down the cell will follow a Gaussian distribution. According to Sueoka<sup>1</sup>, the density  $\rho$  varies with the distance  $r$  from the axis of rotation according to the expression

$$\rho = \rho_0 + A(r^2 - r_0^2) \quad (1)$$

where  $\rho_0$  is the mean density at distance  $r_0$  and  $A$  is a constant for the particular gradient.

According to Meselson *et al.*<sup>2</sup>, if  $\sigma$  is the standard deviation of the concentration versus distance curve, the spread of which results from thermal agitation alone, then for a sample homogeneous in both molecular weight and density,

$$M = RT \{ \bar{v} \omega^2 r_0 \sigma^2 (d\rho/dr)_{r=r_0} \}^{-1} \quad (2)$$

in which  $\bar{v}$  is the apparent partial specific volume of the macromolecules,  $\omega$  is the angular velocity and the other symbols have their usual meanings. If, however, the isolation procedure is such as to produce material which

Rat liver mitochondria, isolated by the method of Myers and Slater<sup>4</sup>, were suspended in a medium containing 15 mmolar KCl, 2 mmolar EDTA, 25 mmolar *tris*-HCl buffer (pH 7.4), 10–15 mmolar potassium phosphate buffer (pH 7.1), 0.1 mmolar ADP, 25 mmolar sucrose (derived from the mitochondrial suspension), 24 mmolar  $\alpha$ -oxoglutarate, 24 mmolar NH<sub>4</sub>Cl, 1 mmolar arsenite, 25 mmolar succinate, and, in series 2, 10 mmolar ATP. The concentration of mitochondria varied between 3 and 6 mg protein/ml. In series 3, the suspension was pre-incubated for 1 h at 25° C before addition of succinate. Reaction at 25° C for 60 min. Uptake of oxygen was measured in Warburg flasks with 0.1 ml. 30 per cent (w/v) potassium hydroxide in the centre well. The reaction was stopped with 0.3 ml. 35 per cent (w/v) perchloric acid, and glutamate determined according to Bernt and Bergmeyer<sup>7</sup>. The values given are means  $\pm$  standard error.

is heterogeneous in density, then the observed standard deviation becomes  $\varphi$  where<sup>3</sup>

$$\varphi^2 = \sigma^2 + \delta^2 \quad (3)$$

and

$$\delta = \gamma / (d\rho/dr) \quad (4)$$

Here  $\gamma$  is the standard deviation of the distribution in buoyant densities.  $\varphi^2$  can be found directly from the concentration distribution curves;  $\sigma^2$  can be determined using equation (2) if  $M$  and  $\bar{v}$  are known. Then from equations (3) and (4) a value for  $\gamma$  can be found.  $M$  can be determined using an independent technique or more readily from measurements of the sedimentation coefficient, using an equation of the form

$$s = \alpha M^\beta \quad (5)$$

in which  $\alpha$  and  $\beta$  are predetermined constants.

Studies have been made using a Spinco model *E* ultracentrifuge on samples of DNA from *Micrococcus lysodeikticus* and *Escherichia coli* prepared by the method of Marmur<sup>4</sup> and on four strains from *Protomyces inundatus* and one from *E. coli* which were isolated by the procedure of Ahmad (in preparation). These groups are designated 1 and 2, respectively. The group 1 *E. coli* DNA was used to calibrate the density gradient by taking its buoyant density as 1.710 g cm<sup>-3</sup> as recommended by Schildkraut *et al.*<sup>5</sup> For the gradient experiments, buffered aqueous solutions of optical grade caesium chloride (Harshaw Chemical Co., Cleveland, Ohio) were used as the density gradient liquid. The procedure outlined by Schildkraut *et al.*<sup>5</sup> was followed. The centrifuge was run at 44,770 r.p.m., which corresponded to a value of 0.0092 for  $A$  (equation (1)). The values of  $\alpha$  and  $\beta$  (equation (5)) were taken as 0.063 and 0.37, respectively<sup>6</sup>, but here it is strictly the weight average molecular weight  $\bar{M}_w$  which is obtained. For samples which are monodisperse in  $M$ ,  $\bar{M}_w \equiv M$ .

Table 1. DENSITY GRADIENT AND VELOCITY SEDIMENTATION RESULTS FOR DNA

Source	Isolation procedure	Buoyant density (g cm <sup>-3</sup> )	$S_{20,w}^0$	$\bar{M}_w(10^{-5})$
<i>M. lysodeikticus</i>	1	1.731	24.1	94
<i>E. coli</i>	1	1.710*	27.0	130
<i>E. coli</i>	2	1.710	10.3	9.9
<i>Protomyces inundatus</i>				
(1) Haploid +	2	1.717	9.7	9.5
(2) Haploid -	2	1.717	8.1	8.4
(3) Natural diploid	2	1.732	9.4	9.4
(4) Artificial diploid	2	1.711	10.2	9.1

Haploids are designated +, -, for convenience. Buoyant densities are to  $\pm 0.001$  except for haploid - which is to  $\pm 0.002$ .

\* Assumed value used to calibrate the density gradient.

All results are shown in Table 1. The buoyant density of *M. lysodeikticus* DNA agrees with the value obtained by Schildkraut *et al.*, confirming the gradient calibration. All group samples gave a value of  $5.1 \times 10^{-4}$  cm<sup>2</sup> for  $\delta^2$  from which  $\gamma = 0.0028$  g cm<sup>-3</sup>, while for group 2 samples  $\gamma = 0$ . The latter value implies samples which have constant buoyant density although they may be polydisperse in molecular weight. For group 2 *E. coli* DNA, however,  $\bar{M}_w$  was also obtained from the density gradient data by performing the vigorous integration over the whole band<sup>2</sup>. The value obtained was, within the experimental uncertainty, that obtained from the sedimentation velocity experiments (equation (5)).

In equation (2) the apparent partial specific volume is used, and its average value may vary with the spread in buoyant density of the macromolecules. For different samples of a single material, each with the same density distribution, the average value of  $\bar{v}$  is not likely to alter significantly. It may, however, vary from distribution to distribution. The values of  $\gamma$  reported here may therefore need slight correction. Nevertheless,  $\gamma$  will still characterize the distribution of buoyant densities within each group.

The equality of  $\gamma$  for the two group 1 samples isolated by the same technique thus gives a measure of support to the use of  $\gamma$  as a preparation parameter; further support comes from  $\gamma = 0$  for all group 2 preparations. Further study is, however, necessary on samples isolated by more techniques and on material from a better identified source.

## Circular Dichroism of Rhodopsin and Isorhodopsin

A COMPARISON between the optical rotatory dispersion curves of rhodopsin before and after irradiation has been previously reported<sup>1</sup>. Unbleached rhodopsin solutions show a weak Cotton effect in the visible range, and another distinguishable Cotton effect in the ultra-violet range, attributable to the polypeptide conformation (probably  $\alpha$ -helix) of the protein moiety, opsin. After bleaching, however, the samples have a simple dispersion curve showing lower values of optical rotation in the visible range. The Cotton effect in the visible range is thus presumably caused by the optical activity of the prosthetic group conformation (11-*cis*), although this is not certain. We have made measurements of the circular dichroism of rhodopsin and isorhodopsin (the artificial pigment with a prosthetic group in the 9-*cis* configuration) in order to elucidate the weak Cotton effect demonstrated by optical rotatory dispersion.

A digitonin extract of cattle rhodopsin was prepared by the usual procedures<sup>2</sup> (outer segments of rod were hardened with potassium alum, freeze dried, washed with light petroleum ether and extracted with 2 per cent aqueous digitonin). The  $E_{400}/E_{500}$  and  $E_{278}/E_{500}$  of the extracts were 0.22 and 2.5. The concentration of digitonin in the extract was about 1.2 per cent. Isorhodopsin was prepared by irradiating rhodopsin solution at the temperature of liquid nitrogen through a filter transmitting more than 590 m $\mu$  (ref. 3) until the  $\lambda_{max}$  of the sample shifted from the initial 498 m $\mu$  (rhodopsin) to 487 m $\mu$  (isorhodopsin<sup>4</sup>). Assuming the molar extinction coefficient of isorhodopsin to be 43,000 and that of rhodopsin to be 40,600 (ref. 4), the irradiated sample was estimated to contain more than 95 per cent of isorhodopsin and less than 5 per cent of rhodopsin, and no other photoproducts (Fig. 1).

Measurements of the circular dichroism between 600 and 200 m $\mu$  were performed at 20° C with the Roussel-Jouan Dichrograph, Type B. The pH of the sample was adjusted to 6.8 with M/15 phosphate buffer. The circular dichroic absorption was expressed as  $\Delta\epsilon_{ir} = \Delta A_{ir}/c.l$ , where  $\Delta A_{ir}$  is the observed difference in absorbance between the left and right circular-polarized components,  $c$  is the molar concentration of rhodopsin or isorhodopsin, and  $l$  is the light path in cm. In the visible range the light path was 1 or 2 cm, but in the ultra-violet range it was only 0.5, 0.2 or 0.1 cm (because of the strong absorbance in this region). Absorption spectra were recorded with the Hitachi spectrophotometer (EPU-2A).

Fig. 1 shows the absorption spectra and circular dichroic absorption spectra of rhodopsin and isorhodopsin in the visible range. Both rhodopsin and isorhodopsin have positive circular dichroic absorptions, each possessing two optically active absorption bands corresponding to the main peaks at 500 and 487 m $\mu$  and to the respective *cis* peaks. It is noteworthy that the optical activity in the *cis* peak region is remarkably high in both cases (for rhodopsin it is rather greater than the optical activity of the main peak).

After irradiation of rhodopsin with  $10^4$  lux for 3 min, the circular dichroic curve in the visible "collapsed" completely to the base line, a result which was also achieved by heating for 5 min at  $90^\circ$  C.

Fig. 2 shows the circular dichroic spectra of rhodopsin in the range 200–250 m $\mu$ . The two lower curves are those before ("dark") and after ("irradiated") bleaching. The upper curve is that of the "dark" sample after four-fold dilution. This curve indicates that rhodopsin contains a considerable amount of polypeptide in the  $\alpha$ -helix conformation in comparison with other helical (synthesized) polypeptides and natural proteins<sup>5</sup>. The decrease in circular dichroic absorbance after irradiation suggests that the change of conformation in the protein moiety occurs when retinal is released from opsin. The circular dichroic spectra in the ultra-violet range are consistent with the earlier data on optical rotatory dispersion<sup>1,14</sup>. A clear circular dichroic spectrum near 278 m $\mu$  corresponding to the absorption of aromatic residues could not be observed, indicating little or no activity of the band in spite of its high absorption.

In the previous report<sup>1</sup>, we ascribed the decrease in  $[\alpha]_D$  on irradiation to be caused chiefly by a conformational change in the protein (because the Cotton effect in the visible was much weaker than in the ultra-violet). The present results, however, suggest that conformational change in the chromophore contributes in a considerable degree to this decrease.

What has induced the optical activity of 11-*cis* retinal? The 11-*cis* retinal molecule is bent in the middle and twisted because of steric hindrance<sup>6</sup>. When bound to opsin, this twisting could be enhanced in one direction—right or left handed—and consequently an optically active (asymmetric) structure might be induced, as is observed in many optically active biaryl compounds<sup>7</sup>. Against this, however, is the fact that although 9-*cis* retinal (in isorhodopsin) has a relatively plain structure<sup>8</sup>, it

Fig. 1. Absorption spectra and circular dichroic absorption spectra of rhodopsin and isorhodopsin in the visible range. *R-abs* and *IR-abs*: absorption spectra of rhodopsin and isorhodopsin. *R-CD* and *IR-CD*: circular dichroic absorption spectra of rhodopsin and isorhodopsin. Measurements at  $20^\circ$  C for 1 cm of light path.

Fig. 2. Circular dichroic absorption spectra of rhodopsin in the ultra-violet range. Bottom curve: rhodopsin solution (at five-fold dilution of Fig. 1. sample) in the visible range. Middle curve: irradiated solution at the same dilution. Top curve: rhodopsin solution at twenty-fold dilution. Measurements at  $20^\circ$  C for a 0.1 cm light path.

likewise becomes optically active, though less so than the 11-*cis* isomer.

In any case, it is probable that the bathochromic shift in the absorption spectrum of retinal-opsin could arise from any strong interaction between retinal and opsin—that would lead to an unsymmetrical conformation for the retinal<sup>14</sup>. The circular dichroic absorption and optical rotatory dispersion in the ultra-violet suggest that an asymmetric conformation of retinal could be imposed by attachment to a rigid conformation (probably  $\alpha$ -helix) of the protein moiety. The fact that the circular dichroic absorption of rhodopsin is greater than that of isorhodopsin suggests that 11-*cis* retinal can be more rigidly fixed to opsin than can 9-*cis* retinal. If this is so, we can understand why the  $\lambda_{\max}$  of rhodopsin is longer than that of isorhodopsin.

The reason why the circular dichroic absorption corresponding to the *cis* peak is so high cannot yet be explained. The electronic transition corresponding to the *cis* peak was tentatively explained by Wald<sup>8</sup> as being perpendicular to the transition corresponding to main peak. The fact that  $E_{cis\text{ peak}}/E_{main\text{ peak}}$  of free 11-*cis* retinal is about 0.5 (ref. 6), while that of bound retinal in rhodopsin is about 0.2, indicates that the electronic transition corresponding to the *cis* peak is much more strongly affected than the main peak by interaction with opsin. We cannot decide, however, whether asymmetric conformation of retinal has been caused by a change in the steric orientation of a local group in the polyene chain, or by a conformational change in the whole polyene chain.

In a late stage of the preparation of this communication we read the article by F. Crescitelli *et al.*<sup>9</sup> dealing with the circular dichroism of rhodopsin and porphyropsin. These authors discussed the induced circular dichroism of visual pigments in the light of the fact that optically inactive dye molecules, when asymmetrically arranged along the ordered conformation of synthesized polypeptides, become optically active<sup>10,11</sup>. They tentatively suggested that the induced circular dichroism of 11-*cis* retinal arose from its steric fitness with opsin, as proposed by Wald *et al.*<sup>12</sup>. We agree with this idea. Takagi *et al.*<sup>13</sup> reported that when flavin adenine dinucleotide (FAD) was bound with D-amino-acid oxidase, the optical activity of FAD was inverted and enhanced. Similar phenomena were found in other natural chromoproteins with a single prosthetic group that was originally optically active. We can find, however, no example other than rhodopsin

in which optical activity has been induced by interaction of a single optically inactive prosthetic group with the ordered structure of a protein moiety. In order to elucidate the retinal-opsin linkage in rhodopsin, and the functional mechanism of rhodopsin in vision, further studies on circular dichroism are required.

We thank Professor I. Honjo for his encouragement and Dr F. Ogura of the Department of Chemistry for his criticism and help. This work was supported in part by grants from the Japanese Education Ministry and the Matsunaga Science Fund.

### Some Physical Properties of Bimolecular Lipid Membranes produced from New Lipid Solutions

ALL bimolecular lipid membranes (BLM) (which are also known as bilayer or black lipid membranes) so far investigated have been formed from solutions containing phospholipids, with perhaps one exception<sup>1,2</sup>. In an attempt to understand more fully the structure of BLM, and in particular the factors responsible for BLM formation and stability, we tried to generate BLM from a variety of substances and to measure their physical properties. Previous measurements of properties have been restricted chiefly to electrical characteristics, thickness and water permeability<sup>3</sup>, but a technique has recently been developed which permits direct quantitative measurements of interfacial tension.

The composition of the lipid solutions which produced stable BLM is given in Table 1. The compounds are all readily available. Cholesterol obtained from various commercial sources was recrystallized twice from absolute ethanol before use, and oxidized cholesterol was prepared by a procedure previously described<sup>2</sup>.

The electrical properties of BLM were measured in a chamber basically similar to the one used by Mueller *et al.*<sup>3</sup>. We measured various electrical properties (Table 1) by inserting two saturated calomel electrodes into the bathing solution across the BLM. The polarizing voltages were applied to the BLM using an instrument designed by Rudin, Mueller and Chock (Electronics for Life Sciences, Rockville, Md.), with which the input resistance can be varied between 0.1 and 1,000 megohms and the polarizing potential between 0 and 5.5 V. The potential across the BLM was monitored with a Keithley electrometer. For quantitative measurements of interfacial tension, the BLM was interposed between two identical aqueous solutions. An infusion-withdrawal pump was used to change the hydrostatic head in one chamber. The resulting pressure difference across the membrane was detected by a sensitive pressure transducer, and was continuously recorded. The pressure reached a maximum when the membrane was hemispherical. The interfacial tension ( $\gamma_i$ ) was calculated from this point using the equation

$$P = \frac{8\gamma_i}{d} \quad (1)$$

where  $P$  is the pressure difference across the BLM and  $d$  is the diameter of the hemisphere. In some experiments, the inner chamber for membrane support was replaced by a length of 'Teflon' tubing inserted vertically in the outer chamber. The experimental apparatus is illustrated in Fig. 1 and the results of interfacial tension measurements are also given in Table 1.

Attempts to form BLM with purified cholesterol, dioctadecyl phosphite (DODP), dodecyl acid phosphate (DAP) or hexadecyltrimethylammonium bromide (HDTAB) alone in *n*-dodecane were not successful. Stable black membranes were obtained, however, when cholesterol was present in combination with a surface active agent (Table 1, lipid solutions A, B, and C). On the other hand, lecithin, glycerol distearate and oxidized cholesterol could all form BLM alone. Low interfacial tension at the oil/aqueous solution interface, although important for the formation of BLM, is not a sufficient criterion to predict the formation of a stable membrane. From our measurements on a number of systems, we conclude that the interfacial tension must be in a given range between slightly higher than 0 and about 6 dynes/cm and that the packing of molecules in the membrane must satisfy some sort of space-charge requirements.

The results given in Table 1 are of particular interest because the Davson-Danielli model of the cell membrane<sup>4</sup> was based on an expected value of  $\gamma_i$  of some 20 dynes/cm for the lipid layer. Because the interfacial tensions measured for cell membranes were of the order of 0.1 dynes/cm, Davson and Danielli concluded that an adsorbed protein layer was responsible for the reduction of the interfacial tension of the lipid leaflet. Although the data presented in this report do not rule out the presence of an adsorbed layer of protein being responsible for low  $\gamma_i$  in the cell membrane, they do indicate that protein adsorption might not be the only cause of the low  $\gamma_i$  found for cell membranes.

Table 1. COMPOSITION OF LIPID SOLUTIONS FOR THE FORMATION OF BIMOLECULAR LIPID MEMBRANES AND SOME PHYSICAL PROPERTIES AT 25° C

Lipid solution (w/v)	Aqueous phase	Interfacial tension (dynes/cm)	Conductance $\times 10^4$ (mhos/cm <sup>2</sup> )	Capacitance ( $\mu F/cm^2$ )	Breakdown voltage (mV)
A, Dioctadecyl phosphite* (0.08 per cent) + cholesterol (0.8 per cent) in <i>n</i> -dodecane	0.1 normal NaCl	3.9 $\pm$ 0.5	1-10	0.74 $\pm$ 0.01	350
B, Dodecyl acid phosphate* (0.35 per cent) + cholesterol (0.93 per cent) in <i>n</i> -dodecane	0.01 normal NaCl	1.1 $\pm$ 0.1†	1	0.69 $\pm$ 0.03	800
C, Cholesterol (~1 per cent) in <i>n</i> -dodecane	0.001 normal NaCl + 0.008 per cent HDTAB	0.65 $\pm$ 0.1	0.5	0.79 $\pm$ 0.03	300
D, Egg lecithin (1 per cent) in <i>n</i> -dodecane	0.1 normal NaCl	0.9 $\pm$ 0.1	0.5	0.45 $\pm$ 0.04	120
E, Glycerol distearate (sat.) in <i>n</i> -octane	0.1 normal NaCl	1.5 $\pm$ 0.1	0.5	0.39 $\pm$ 0.01	120
F, Oxidized cholesterol (4 per cent) in <i>n</i> -octane	0.1 normal NaCl	1.9 $\pm$ 0.5	0.5	0.57 $\pm$ 0.01	310

\* Supplied by Hooker Chemical Co., NY

† In 0.1 normal NaCl

Conductance measurements can be duplicated within an order of magnitude or better, and breakdown voltage usually within 15 per cent. Capacitance values are given with standard error for 3-9 experiments.

Fig. 1. Apparatus for measuring interfacial tension of bimolecular lipid membranes. C, Ballast chamber; T, 'Teflon' tubing; BLM, membrane or thin lipid film.

Finally, the apparatus described can be used to study the effects of adsorption of electrolytes, drugs and other substances on bimolecular lipid membranes. These membranes have already been shown<sup>5</sup> to be a promising tool in the understanding of biological phenomena in relation to their reactions and behaviour. The apparatus should also be useful for the study of other types of interfacial films and associated adsorption phenomena at oil/water interfaces<sup>6,7</sup>.

This investigation was supported by grants from the US National Institutes of Health.

### Substrates of Kinin-releasing Enzymes isolated from Horse Plasma

KININOGEN has been isolated from horse plasma<sup>1</sup>, bovine plasma<sup>2-4</sup>, human plasma<sup>5</sup> and rabbit plasma<sup>6</sup>. Several authors, however, have shown that plasma contains at least two kininogens with affinities for different releasing enzymes<sup>7-10</sup>. Recently, Jacobsen<sup>11</sup> detected the presence of two kininogens in human, dog and rabbit plasma—one which forms kinin with plasma kallikrein and another which forms kinin only when incubated with glandular kallikrein.

We have previously shown<sup>1,10</sup> that although a kininogen isolated from horse plasma released kinin when incubated with trypsin and snake venom enzyme, it did not do so when incubated with plasma kallikrein. The observation that fresh or inactivated plasma was rich in substrate for plasma kallikrein<sup>10</sup> induced us to try to separate these two substrates in the course of the same chromatographic procedure. The first kininogen which emerged from the DEAE-cellulose column was the substrate specific for plasma kallikrein and will be referred to here as kininogen I; the second kininogen was the same as that isolated previously<sup>1</sup> as "bradykininogen", and will here be called kininogen II.

Fresh oxalated horse plasma was heated to 61° C for 20 min to destroy the endogenous formation of kinin<sup>12</sup>. Ammonium sulphate was added to 20 per cent saturation, and after separation of the inactive precipitate the concentration of ammonium sulphate was increased to 35 per cent. The precipitate was separated by centrifugation, dissolved in a small volume of water and dialysed in the cold (4° C) in 'Cellophane' tubing, first against water and then against 5 mmolar sodium phosphate buffer, pH 7.0, until the diffusate was free from  $\text{NH}_4^{++}$  ions. The residue was then passed through a DEAE-cellulose column equilibrated with the same buffer. A gradient was established by introducing 0.02 molar phosphate buffer, pH 6.5; 0.05 molar phosphate buffer, pH 6.0; 0.05 molar  $\text{Na}_2\text{HPO}_4$  in 0.1 molar NaCl; and 0.1 molar  $\text{Na}_2\text{HPO}_4$  in 0.2 molar NaCl, from a separating funnel into a chamber containing 5 mmolar sodium phosphate buffer, pH 7.0. The ultra-violet absorption of the fractions was recorded at 254 m $\mu$ . The presence of the substrates in the various fractions was determined by assay on the guinea-pig ileum of the bradykinin formed by incubation of the fractions with purified plasma kallikrein<sup>10</sup> and the kinin-releasing enzyme from the venom from *Bothrops jararaca*<sup>12</sup>. Kininogen I was eluted from the anion exchange column at a sodium phosphate concentration of approximately 0.017 molar. Kininogen II was eluted at a concentration of 0.09 molar in sodium phosphate and 0.16 molar in sodium chloride and was further purified as previously described<sup>1</sup>. The active fractions containing kininogen I were further purified by gel filtration on a column of 'Sephadex G-100' in 5 mmolar phosphate buffer, pH 7.0 (Fig. 1). Fractions 30-40, which contained the peak of

Fig. 1. Fractionation of kininogen I on 'Sephadex G-100'. Elution pattern of DEAE-cellulose purified material (12.5 ml.; 437 mg protein). Column dimensions: 2.2 cm × 35 cm. Fraction volume was 7 ml.

activity, were combined and the protein content was determined by the method of Lowry *et al.*<sup>14</sup>. An overall purification factor of about 200 was obtained in terms of capacity to produce kinin when incubated with plasma kallikrein, as compared with the globulin fraction precipitated at 35 per cent saturation with ammonium sulphate. The chromatographic and gel filtration experiments were performed at 4° C.

Kininogen I releases kinin when incubated with plasma kallikrein, snake venom enzyme and trypsin, while kininogen II releases kinin when incubated with trypsin, venom enzyme, urinary kallikrein and plasmin<sup>10</sup> but not with plasma kallikrein.

We thank Dr D. F. Elliott of Ciba Laboratories Research Division, Horsham, Sussex, for the gift of bradykinin.

## HAEMATOLOGY

### Reaction Sequence of Blood Coagulation

IN 1964 Macfarlane<sup>1</sup> proposed a reaction mechanism for the interaction of blood coagulation factors, known as the enzyme cascade. In this hypothesis the blood coagulation factors as they occur in plasma are considered to be zymogens (except factor I; namely, fibrinogen). Coagulation is initiated by the conversion of one of these zymogens into an enzyme as a result of contact with anything other than intact vascular endothelium. This enzyme then acts on another clotting factor to form another active enzyme. All clotting factors thus interact in a given order until prothrombin (factor II) is converted into thrombin. Thrombin then brings about the actual coagulation by converting fibrinogen into fibrin.

The prothrombin converting activity (prothrombinase activity) was first thought to be exerted by activated factor V (ref. 1). As the result of further work it now seems that the prothrombinase activity is displayed by a complex of activated factor X (*f.X<sub>a</sub>*), calcium ions (II) and factor V (*f.V*) which are adsorbed together on a phospholipid surface.

The evidence for this concept is of two kinds. (a) It can be shown that *f.X<sub>a</sub>* and *f.V* are bound by phospholipid micelles, and that calcium ions favour the binding of *f.X<sub>a</sub>*. High concentrations of calcium, however, inhibit the binding of *f.V* (refs. 2-5). (b) The kinetics of the generation of prothrombinase activity in mixtures of *f.X<sub>a</sub>*, *f.V*, phospholipid and calcium ions can be explained by assuming that a product of all four reactants is the

*f.II* converting substance. It cannot be explained by a reaction of the cascade type<sup>6</sup>.

This communication shows that evidence can also be provided for the existence of a complex consisting of the clotting factors IX (in activated form) and VIII, and phospholipid, similar to that described in section (a). The interaction between *f.IX<sub>a</sub>* and *f.VIII* previously has been considered to be of the cascade type, that is

The experiments described in Table 1, however, show a strong similarity between the characteristics of adsorption

Table 1. ADSORPTION OF COAGULATION FACTORS BY PHOSPHOLIPID

Calcium ion conc. (mmolar)	Percentage of clotting factor adsorbed			
	V	VIII	IX	X
1	60	58	27	38
50	<1	41	45	60
100	<1	3	68	76

The figures give the means of three different experiments. Each coagulation factor determination was carried out eight times. The material used as a source of *f.V* and *f.VIII* was barium sulphate adsorbed bovine oxalated plasma. For *f.IX<sub>a</sub>* and *f.X<sub>a</sub>* oxalated bovine serum was used as a source. To prevent active thrombin being formed from residual amounts of prothrombin, 5 mcg/ml. hirudin was added. The phospholipid used was a suspension of inosithin prepared by homogenizing the crude material in *tris-HCl* buffer 0.02 molar, pH 7.5 containing 0.14 molar NaCl. The reaction mixture consisted of 0.9 ml. plasma or serum, 0.4 ml. CaCl<sub>2</sub> solution in *tris-HCl* 20 mmolar pH 7.5; 0.4 ml. of a suspension of inosithin 5 mg/ml. Half the mixture was centrifuged for 30 min at 100,000g at 4° C; in the supernatant the original concentration of phospholipid was restored. The other half of the mixture was stored at 4° C and served as a control. The concentration of the clotting factors in the centrifuged sample was determined and expressed as a percentage of that in the control. The percentage adsorbed was calculated as the amount not recovered in the supernatant. Factors VIII and IX were estimated according to Veltkamp<sup>7</sup>, factors V and X were estimated as described in ref. 10. The concentration of hirudin used did not interfere with the clotting factor determinations.

onto phospholipid of *f.X<sub>a</sub>* and *f.IX<sub>a</sub>*, on the one hand, and of *f.V* and *f.VIII*, on the other. Calcium ions favour the adsorption of *f.X<sub>a</sub>* and *f.IX<sub>a</sub>*; excess calcium inhibits the adsorption of *f.V* and *f.VIII*. Control experiments show that it is the phospholipid that adsorbs the clotting factors. The activity that disappeared from the supernatant could be recovered from the resuspended phospholipid sediment. No activity was recorded from the phospholipid in experiments in which no activity was adsorbed from the sample.

The role of phospholipid in the interaction of *f.IX<sub>a</sub>* and *f.VIII* has so far remained obscure, although it has been proved that this role is a mandatory one<sup>7</sup>. Our experiments strongly suggest that phospholipid interacts with calcium ions, *f.IX<sub>a</sub>* and *f.VIII* in a manner similar to the interaction of phospholipid, calcium, *f.X<sub>a</sub>* and *f.V*. If this is true, the reaction equation of the interaction would be

Theoretically, it is possible to obtain more evidence for the existence of complex A by investigating the kinetics of the generation of *f.X* converting activity from the purified factors IX<sub>a</sub> and VIII, that is, by a procedure analogous to the experiments cited in section (b). Technical difficulties in obtaining the pure factors IX<sub>a</sub> and VIII as well as in the measuring of the conversion *f.X*  $\longrightarrow$  *f.X<sub>a</sub>* seem to prevent this approach in the near future.

The fact that kinetic evidence obtained with impure systems has so far suggested that *f.VIII* is converted enzymatically by *f.IX<sub>a</sub>* (ref. 8) remains disturbing. From the results of experiments on the kinetics of the interaction of factors X<sub>a</sub> and V, it was evident that if only a limited range of concentrations was investigated, the results obtained simulated that of an enzyme inter-

action. If the experiments were carried over a wide range of concentrations then the stoichiometric interaction is suggested<sup>6</sup>.

We have paid no attention to the form in which f.V and f.VIII participate in the reactions. By this we do not mean to say that we suppose them to be in the unmodified form in which they occur in intact plasma.

The considerations presented here suggest the following scheme of the intrinsic reaction mechanism of blood coagulation

We thank the Netherlands Foundation for Chemical Research (SON) and the Netherlands Organization for the Advancement of Pure Research (ZWO) for support.

## IMMUNOLOGY

### Tolerance in Adult Rats to a Purified Protein, Flagellin, from *Salmonella adelaide*

THE capacity of flagellar antigens from *Salmonella adelaide* to induce immunity and tolerance in rats has been described in detail before<sup>1</sup>. The monomeric protein, flagellin, prepared from the flagella of this organism has been purified. It has a molecular weight of about 38,000 and contains in particular three methionine residues, but no cysteine, histidine or tryptophan. Flagellin was readily polymerized by treatment with ammonium sulphate to form linear polymers which under the electron microscope looked the same as the original flagella particles<sup>1,2</sup>. These proteins were highly immunogenic in the adult rat; amounts of less than 1 µg, when injected in saline, gave rise to readily detectable amounts of antibody<sup>3</sup>. Tolerance to flagellin has been previously described in newborn<sup>4</sup> but not in adult rats. Tolerance has now been achieved in adult rats by the injection of flagellin degraded by cyanogen bromide, a reagent which cleaved the polypeptide chain at methionine residues.

The polymer (20 mg) in aqueous solution was deposited by centrifugation (30,000g for 45 min) and the residue was

dissolved in formic acid (1 ml., 100 per cent). Cyanogen bromide (40–60 mg) was added and the mixture was incubated at 20° C for 16 h. The reaction products were examined by polyacrylamide gel electrophoresis. At all pH values used, flagellin showed a single band of protein, and so did flagellin treated with formic acid alone. The best resolution of the reaction products resulting from cyanogen bromide treatment was achieved in an acetate buffer of pH 2.7 containing 8 molar urea<sup>5</sup>. The separation achieved is shown in Fig. 1. There were four chief protein bands called fragments A, B, C and D which were well separated from the position where intact flagellin would band. There were in addition three or four very narrow, minor bands immediately above fragment A but below the expected position of intact flagellin. It was initially thought that these minor bands might represent incomplete cleavage of the flagellin molecule. Amino-acid analysis of the reacted protein showed, however, that the destruction of methionine seemed to be complete so that the three or four minor bands in the polymer digest might represent recombined fragments of the flagellin molecule<sup>6</sup>.

Fig. 1. Polyacrylamide gel electrophoresis in an acetate buffer, pH 2.7, containing 8 molar urea of flagellin and of a cyanogen bromide digest of the polymer. Protein bands were stained with amido black (0.25 per cent, w/w) in 7 per cent (v/v) acetic acid containing mercuric chloride (0.5 per cent, w/w). Flagellin gave a single band (left) whereas the digest gave four main bands, designated fragments A, B, C and D. The degree of cross hatching approximates the intensity of staining observed.

The antigenic properties of the protein digest (hereafter called the digest) were examined by studying the reaction with anti-flagellin rabbit serum. Immunodiffusion analysis showed a complete line of identity between flagellin, the digest and fragment A, suggesting no destruction of antigenic determinants during the cyanogen bromide treatment. When tested by a micro precipitin reaction (carried out by Dr R. Wistar) the digest was found to retain completely the ability to react with anti-flagellin serum. The digest was also compared with flagellin for its ability to neutralize the immobilizing activity of a given amount of anti-flagellin serum when mixed with a motile suspension of organisms (*S. derby*, which shares the same H antigens as *S. adelaide*). The digest was found to be about 50 per cent as efficient as flagellin in this regard.

The *in vivo* behaviour of the digest was compared with that of the intact antigen. When a single dose of different preparations of the digest in aqueous solution was injected into the footpads of adult rats (10 µg each rat—randomly bred Wistar rats were used), either no antibody or very low titres of antibody was detected (antibody titres were

Fig. 2. Antibody titres in rats which had been subjected during 4 weeks to daily injections of either polymer (O), flagellin (□) or a cyanogen bromide digest of flagellin (Δ).

measured by the bacterial immobilization technique which has a sensitivity of about 15 ng/ml. of antibody—unpublished results of Lang and Ada). In contrast, the digest was as efficient as flagellin in (a) inducing antibody formation when injected with complete Freund's adjuvant and (b) initiating a secondary response in rats previously injected with flagellin. The possibility that the digest injected in saline was effective in inducing tolerance in adult rats was studied by injecting groups of 6–7 week old rats intraperitoneally on day 1 with 500  $\mu$ g, and on each successive day for 4 weeks with 100  $\mu$ g of either polymer, flagellin or the complete digest. The antibody titres which resulted are shown in Fig. 2. The repeated injection of either polymer or flagellin resulted in high titres of antibody whereas very low titres of antibody were observed after injection of the digest. Thirteen out of twenty rats in the latter group showed no detectable antibody production. These thirteen rats were challenged immediately at the end of the 4 week period by injections into the footpad as follows: five with 100  $\mu$ g of flagellin in saline; five with 100  $\mu$ g of flagellin in complete Freund's

adjuvant; and three with 100  $\mu$ g of polymer in saline. At the same time other rats (not previously injected) were injected with 100  $\mu$ g of flagellin in saline or in complete Freund's adjuvant. In addition, those rats which had received the course of injections of 100  $\mu$ g of flagellin for four weeks were challenged with a further dose of 100  $\mu$ g of flagellin (injected into the hind footpads). The results in Fig. 3 clearly show that rats receiving the complete course of flagellin injections maintained high antibody titres. In contrast, those rats which had received the full course of injections of digest were almost completely tolerant, not only to flagellin in saline but also to flagellin in complete Freund's adjuvant. Each of the three rats which had been challenged with polymer gave low but definite antibody titres, the average value at 3 weeks being less than 10 per cent of control values. At present experiments are in progress to see whether only fragment A of the digest is necessary to confer tolerance in adult rats. It seems likely that a decrease in the size of the antigen molecule reduces the immunogenic potential but allows adult tolerance to be induced.

It seems important to extend this work to other systems (unpublished results of Bonavida, Miller and Sercarz). It is possible, for example, that if a histo-compatibility antigen could be partially degraded without loss of antigenic determinants injection of such a preparation could bring about tolerance in adult animals not only to the intact antigen but possibly also to the cells from which the antigen was derived.

This work was supported by grants from the National Health and Medical Research Council, Canberra, and from the Australian Research Grants Committee.

Fig. 3. Antibody titres in rats which had been given for 4 weeks a course of injections of (a) flagellin and challenged with flagellin in saline (□), and (b) cyanogen bromide digest of polymer and challenged with a single dose of flagellin in saline (○), or flagellin in complete Freund's adjuvant (CFA) (●). Control (previously uninjected) rats were injected with flagellin in saline (▽) or flagellin in CFA (▼).

## PSYCHOLOGY

### Timing of Cognitive Responses in Naming Tasks

THE processes of perception are currently envisaged as organized into hierarchies of tests for criterial attributes of stimuli<sup>1-3</sup>. Analysis of stimulus information may be total or partial, and the tests arranged in series or in parallel. This general conceptual approach derives primarily from studies of intelligibility in dichotic listening, but finds support from studies of word recognition, and from visual search studies in which time is the principal<sup>4</sup> measure of performance.

Theories of perceptual organization have been based primarily on error data, but it seems important to take latency data into account also in any attempt to develop current models. This view is encouraged by the fact that in a short term memory task, error and latency data may behave quite differently in response to experimental treatments<sup>5</sup>. There is less direct evidence from perceptual studies, but Pollack's demonstration<sup>6</sup> of differences in reading speed according to whether subjects named individual items or their class membership may be com-

pared with Moray's<sup>7</sup> failure to find differences in recognition thresholds assessed on the basis of item or superordinate responses.

Oldfield and Wingfield<sup>8</sup> recently showed that latencies of discrete naming responses to drawings of objects depend on the frequency of the object name in the language. They interpret the latency differences as reflecting relative access times to the requisite parts of a "neural dictionary", and hence as throwing light on underlying systems of classification in the brain. The general method seems versatile and is suitable for the investigation of other wider aspects of cognitive organization often subsumed under "thinking" and "sensorimotor skills"<sup>9,10</sup>.

The experiments reported here were planned to illustrate some advantages of the approach, rather than to produce evidence at this stage favouring any specific theory. They concern principally the effect on response latencies of the nature of the coding operations carried out. In both experiments, the responses were single common words relating to stimulus dimensions. The tasks could be regarded, in part at least, as search tasks without a spatial component.

Each stimulus complex comprised a superimposed letter and digit stencilled on white card, in contour to avoid mutual occlusion. One member of each digit-letter pair was red, the other green. Twenty-four letters, I and O excluded, occurred twice, once in each colour. The digits 2-9 inclusive occurred in random combination with the letters, with frequencies balanced as far as possible. The cards were exposed in a tachistoscope for 0.5 sec in experiment 1, and 1.0 sec in experiment 2.

Verbal response latencies were measured with a 'Digitron' timer which was started at the onset of presentation and stopped by the subject's voice through a throat microphone and voice key relay. Presentations were manually controlled by the experimenter in the first experiment. In experiment 2, the subject was given control of presentation in order to try to increase the sensitivity of the method.

Twelve male undergraduates in each experiment met all conditions (see Table 1) in balanced Latin square designs. They were told to respond as rapidly as possible and to avoid errors. Each condition occurred in a block of eight consecutive trials in experiment 1 and of twelve consecutive trials in experiment 2. The conditions were described to the subject before the experiment began, and again before each block of trials, and specific instructions were given before each single trial. In conditions 5 and 6, the specified class and colour respectively alternated on successive trials. In experiment 1, there was no training beforehand. In experiment 2, one practice series was given for each condition in counterbalanced order.

Table 1. CONDITIONS AND MEAN MEDIAN LATENCIES

Condition	Task requirement	Reaction time (msec)			
		Exp. 1	$P < 0.05$	$P < 0.01$	Exp. 2
1	Name number, given its colour	739	}	}	594
2	Name number	778			627
3	Name colour, given the number	884			
4	Name item, given a colour	955	}	}	
5	Name class, given a colour	1,109			
6	Name colour, given a class	1,163			

Brackets enclose means which do not differ significantly at the specified levels.

The overall error rate was very low (around 1-2 per cent). In experiment 1, the significances of differences in response speeds between conditions were assessed by a Keuls extension to a parametric analysis of variance of individual median latencies for correct responses<sup>11</sup>. The results are summarized in Table 1. A similar analysis of variance in experiment 2 showed that the difference between conditions 1 and 2 was significant ( $P < 0.05$ ) in this case. Effects of order (practice effects) and subjects were significant in both cases.

The results seem to warrant the following conclusions.

**Item Responses.** A small advantage can be gained if the subject knows the colour of the target item. This

finding extends the generality of results of visual search tasks<sup>12,13</sup> to a situation in which relevant and non-relevant shape information have a common spatial source (conditions 1 and 2 in experiment 2).

Item naming is slowed by enlarging the stimulus ensemble, or more probably by mixing response classes (compare Pollack<sup>4</sup>) (conditions 2 and 4).

**Colour Responses.** Cognitive operations take longer on the basis of prior class information than if the "target" item is specified (conditions 3 and 6).

**Class Responses.** Superordinate responses are considerably slower than item responses (conditions 1 and 4 versus condition 5). Handling of superordinate information in general (conditions 5 and 6) seems rather inefficient in terms of speed, although there was little or no evidence of lower accuracy of performance.

**Other Comparisons.** Advance colour information seems more advantageous than advance shape information (conditions 1 and 3). This may be because colour analysis is usually carried out at earlier stages in the central nervous system than shape analysis, and may be completed sooner.

When the colour is known, the naming of digits is fastest, the naming of items (either class) is next, and naming superordinate classes is slowest.

Insofar as digits are named more quickly when some sensory attribute (colour) of the target item is known, the results appear consistent with a hierarchical classificatory system like that of Treisman<sup>3</sup>. The markedly longer latencies for specifying the broader, superordinate class, however, would not be predicted on her model. They suggest that the identification of individual items may represent the end of a hierarchical chain, and are more consistent with the slightly different cognitive grouping of Forgas<sup>2</sup>. It is probably relevant that class identifications concern the utilization of disjunctive stimulus attributes.

The data thus suggest inferences about the organization of classificatory processes in cognitive tasks. These depend on more systematic study of the effects of extended practice and on more detailed analysis of the data than has been attempted here. It seems probable, however, that the results as they stand could be accommodated by three principles. (a) Information handling is speeded if the subject is able to focus on a relevant item immediately; (b) an increase in the amount of information to be handled leads to slowing of response; (c) Response latency increases with the number of processing stages through which information passes (compare Fitts<sup>10</sup>). Furthermore, a verbal latency method may yield reliable differences between conditions with a surprisingly small number of readings.

I thank Janice Newman and Clive Barcham, who carried out the preliminary work, and Dr Fergus Craik, Mr Alec Walbridge and Mr Jules Davidoff for their advice.

## BOOK REVIEWS

### AN INSTRUMENT DEVELOPS

#### Historical Aspects of Microscopy

(Papers read at a one-day conference held by the Royal Microscopical Society at Oxford, 18 March, 1966.) Edited by S. Bradbury and G. L'E. Turner. Pp. 227. (Cambridge: W. Heffer and Sons, Ltd., 1967.) 42s. net.

#### The Evolution of the Microscope

By S. Bradbury. Pp. x+357. (Oxford, London and New York: Pergamon Press, Ltd., 1967.) 80s. net.

THE papers from a meeting of the Royal Microscopical Society at Oxford are now published in the form of a book of essays in which experts deal with six subjects connected more or less directly with the history of the microscope. Some of these topics are of a general philosophical kind, some deal particularly with the instruments collected in the Oxford Museum of the History of Science and elsewhere. The contribution by Dr A. C. Crombie deals with the emergence of the physiology, psychology and philosophy of vision, the most fascinating of the special senses.

The establishment of communication between the mechanisms of nature and the spirit of man clearly involved difficulties of conception which did not disappear when the optical system of the eye had been recognized as analogous to that of artificial instruments. Kepler at the outset of the seventeenth century, and Descartes a few decades later, pursued the problem, and physiological optics remained attractive for the remainder of the century to Christopher Wren and to Isaac Newton himself.

A paper by Joseph Needham and Lu Gwei-Djen reveals from a study of local historical sources a group of men of the seventeenth century who worked in south-east China on making spectacles and other instruments. There is some difficulty about translating and interpreting the names of these instruments; they seem to include both telescopes and microscopes as well as spectacles, magic lanterns, and searchlight projectors.

A paper by Dr J. R. Levene is concerned with the accommodation mechanism of the eye as it appeared before, and early in, the nineteenth century. Young presented a paper on the subject in 1793, and Sir Everard Home devoted his Royal Society Croonian lecture in 1794 to experiments to find whether the crystalline lens and its elastic capsule were responsible for accommodation. He came to the conclusion that accommodation was possible when the lens had been surgically removed, and with the collaboration of the celebrated instrument maker Ramsden, who devised an instrument for measuring changes in the curvature of the cornea, he concluded that curvature changes in this could produce some of the accommodation and that changes in the length of the eyeball could produce the rest.

An interesting paper by Dr S. Bradbury specifically devoted to the instrumental history of the microscope gives the results of applying modern test objects and comparison with modern optical systems to early microscopes in museum collections, particularly English instruments of the era 1700-1840. The old instruments were corrected individually and empirically, and not by the application of systematic optical design methods, and so it is not surprising that they are inconsistent in quality one with another. They are usually heavily afflicted with chromatic and spherical aberration, even after the aperture has been stopped down, so that the resolution is much reduced compared with that usually attained by

modern optical systems of the same magnifying power. The theoretical work of J. J. Lister about 1830 on the removal of aberration was followed by the improvements in technology which allowed the production of satisfactory achromatic objectives.

A paper by Mr G. L'E. Turner is concerned with the quantitative aspect of the increase in microscope resolution over the years. This can be followed largely because of the contemporary use of test objects in the form of gratings ruled on glass by the German Nobert. The production of these plates had a definite effect in encouraging the improvement of objectives, because they were made with progressively finer rulings and the last of them went beyond the theoretical limit of the optical microscope. Mr Turner and Dr Bradley examined one of Nobert's test plates owned by the Oxford Museum, using an electron microscope and a replica technique.

The paper by T. Mulvey deals with the early history of the electron microscope which lies quite near to our own day, but which is very interesting to read in summary form. When Abbe had shown that the wavelength of light set an inescapable limit to the resolution of the optical microscope, he realized that a new sort of radiation of short wavelength was needed, but it was not then apparent that electrons filled this need. In the 1920s electron beams had an important application in oscillography and were being studied, particularly in Germany, on that account. The science and technology of electron optics arose in the hands of Gabor, Busch and others. Gabor, working then in Berlin, was responsible for the short ironclad coil as an electron lens, and from this device arose the two-lens microscope of Ruska and Knoll. In 1934 it was found possible to use an electron microscope to photograph a botanical specimen stained with a heavy metal, and to surpass the resolution of the optical microscope. Development and commercial construction of electron microscopes took place in Germany, Britain and the United States, France, Holland and Japan. The instrument entered the decade of 1940 in a well-engineered state capable of continued development, which, of course, goes on.

During the past four hundred years the microscope has kept its place as the most characteristic instrument of biological science, and it is most interesting to have its history laid out in the book by Dr Bradbury. For a physicist it is chastening to find how little has arisen from the systematic use of optical theory—the first man to do so with effect was probably J. J. Lister, the father of the surgeon, who in 1830 showed that a doublet lens could be freed simultaneously of chromatic and spherical aberrations for a particular position of object and image. More recently, about 1880, Abbe applied wave optics to microscope resolution, revealing that the smallest distance which could be resolved was limited by the wavelength of light and the angle of the light which could be accepted by the object glass. With Abbe the microscope entered the phase of fully scientific design and advanced manufacture, for he not only recognized the natural limit of resolution, but he designed apochromatic objectives with unexampled sophistication of correction. This enterprise required the foundation of a new optical glass industry, and Abbe was mainly responsible for the administrative and industrial innovations of the Zeiss-Schott organization which established for the time the overwhelming superiority of the German optical industry. But until these comparatively recent times the microscope developed by the efforts of isolated scientific enthusiasts and craftsmen-artists. In early days the "single microscope", a powerful magnifying glass, competed successfully with the two-lens "compound microscope", and one of Bradbury's chapters is devoted to single microscopes, particularly between 1650 and 1820. Their most conspicuous disadvantage was the very short working distance, which made them uncomfortable to use. One of their most famous users was Leeuwenhoek,

who worked at Delft about 1700, and who communicated regularly with the Royal Society. He has some claim to be considered the founder of the sciences of bacteriology and protozoology. Some of the simple microscopes which he constructed for himself survive and show a resolution of three or four microns. Compound microscopes were regularly constructed in the eighteenth century, and achromatic objectives began to appear about 1800

H. J. J. BRADDICK

## MATHEMATICS AND PROBABILITY

### Green's Function Methods in Probability Theory

By Julian Keilson. (Griffin's Statistical Monographs and Courses, No. 17.) Pp. viii+220. (London: Charles Griffin and Co., Ltd., 1965.) 40s. net.

THE formal identity between mass distribution and probability distribution is so exact that it is always surprising to see how independently the mathematical methodologies of the two fields have developed. The statistician who reflects on the stimulus the problem of moments gave to Karl Pearson's foundation of the modern theory of statistics is apt to wonder whether a second such stimulus is not imminent. This book is not it. Yet this project has been so thoroughly and effectively carried out that one is tempted to infer that the two fields have evolved beyond the point where hybridization remains fertile.

Dr Keilson gave the material of the book as lectures when he was visiting the University of Birmingham and some of us in other universities were able to read the cyclostyled course-notes. The published version has been heavily revised with the help of Dr D. M. G. Wishart so that not only is it extremely clear and easy to read but one may be sure that no possible application to probability of the Green's function methods discussed here will have been overlooked. The facts that (as earlier reviewers have noted) substantially no result has been obtained that is not already known to probabilists in the chosen field of application (Markov processes with associated boundary problems), and that on the whole the probabilists' methods are simpler, if more *ad hoc*, suggest that Green's function methods serve no function in probability theory.

D. E. BARTON

## HARDWARE AND SOFTWARE

### Computer Programming and Computer Systems

By Anthony Hassitt. (Academic Press Textbooks in the Computer Sciences edited by Anthony Ralston.) Pp. x+374. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 86s.

Now that we have sophisticated problem-oriented languages, writing a computer programme is easy. It is still difficult, however, to write a good programme because to do this we need to understand how the software interacts with the hardware, that is, how the systems programmes that convert the higher-level language into the machine-level language and control the job-sequence interact with each other and with the processor, the store and the peripheral devices. This book is a praiseworthy attempt to introduce these concepts to scientific programmers with a basic knowledge of Fortran or another compiler language, and to impart to them a "reading knowledge" of the language produced by the compiler. It is not intended to teach the student, still less to encourage him, to write programmes in machine-level languages; as the author states, the days are past when machine time could be taken as the sole index of efficiency in programming.

That this laudable object of getting the programmer to understand the backstage workings of the compiler is not likely to be wholly attained is not so much the fault of the author, who obviously has considerable relevant experience and expounds his material clearly, as of the

time when the book was written—a time of great change in computers and the ways of using them. Much of the discussion is based on the 7090 and its monitor system and Fortran compiler, and so has to describe the surmounting of many difficulties that would not arise with a more modern computer system and a language better adapted for character and file handling. Although the current practice is described also, it would be much less confusing for the student if the historical tribulations were confined to the excellent introductory chapter.

The dual intention, of providing a textbook for the student of computer science and a reference book for the scientific research worker using the computer as a tool for solving his own problems, has caused the treatment of machine-level language to fall between two stools: it is rather too shallow for the former and too detailed for the latter, who might benefit more from a macroscopic flowchart approach to compilers than from the microscopic code approach. The book is arranged sensibly for use as a student text, with problems at the end of each chapter, but the organization of the material is not ideal for its potentially more valuable use as a reference book. The index in particular is not satisfactory, and one has to refer frequently to the contents list as a supplement: for example, although system 360 is discussed in detail in several chapters, the only index reference to it is to the explanation of virtual memory and time-sharing principles as exemplified in the 360/67. One of the most useful features is the excellent critical comparison of different implementations of Fortran, but the index entry "Fortran" gives ten references without stating which are general, which are to specific dialects and which are to the comparative discussions.

The book should be very useful to conscientious programmers using batch-processing techniques, despite the shortcomings mentioned. A second edition could be considerably improved by the inclusion of more information on disk-oriented systems, an introduction to the functioning of command-language systems for conversational working, and some drastic pruning of the discussion of obsolescent systems. An aesthetic improvement would be the upgrading of the printing of some tables which have been reproduced direct from line-printer output, an irritating design fault in an otherwise well-produced book.

JOHN HAWGOOD

## ADVANCES IN BASIC SCIENCE

### Some Recent Advances in the Basic Sciences

Edited by A. Gelbart. Vol. 1: 1962, 1963, 1964. (Belfer Graduate School of Science—Annual Science Conference Proceedings.) Pp. xii+228. (New York, N.Y.: Belfer Graduate School of Science, Yeshiva University, 1966. Distributed by Academic Press, New York and London.) 68s.

THE Belfer Graduate School of Science at Yeshiva University has sponsored annual conferences on "Some Recent Advances in the Basic Sciences" since 1962. This beautifully produced volume contains the proceedings of three such conferences.

Basic science here means mathematics and physics, with equal emphasis on both subjects. We are thus presented with fourteen discourses which cover the entire field of the exact sciences. The authors are, as one would expect, of impeccable standing in their subjects and they have interpreted their task in very varying ways. He would be a bold reviewer who attempted to do justice to this fare.

Starting with physics, two contributions, one by C. H. Townes, R. Y. Chiao and E. Garmire on "The Interaction of Intense Light Waves and Mechanical Motions in Extended Media", the other from W. A. Fowler, "A Quasar Model based on Relaxation Oscillations in Supermassive Stars"

are models of scientific writing, and can be read with enjoyment by any scientist. C. N. Yang's brief note, "The Mass Formula of  $SU_3$ ", deals with a problem which has since found a reasonably satisfactory solution, whereas Professor Dirac's lecture on the "Foundation of Quantum Mechanics" is concerned with showing that the Heisenberg and Schrödinger pictures do not necessarily provide the same answers in quantum field theory. Both these contributions are really highly technical, although written in a way which obscures this fact. R. Serber's talk on "High Energy Scattering" deals very nicely with the application of optical and diffraction theoretical techniques in this area, and an amusing discourse on "Weather Modification: Prospects and Problems", by G. J. F. McDonald, makes for light reading. Finally, P. Bergmann's talk on "General Relativity in Contemporary Physics" is a non-technical exposition in a somewhat conservative hue.

Turning to the mathematics, things get very tough. Only Chern on "Geometric Structures on Manifolds and Submanifolds" makes any concessions to the non-initiated. Harish-Chandra on "Harmonic Analysis on Semisimple Lie Groups", N. Jacobson on "Forms of Algebras", A. Beurling on "Local Harmonic Analysis", D. C. Spencer on "The Theory of Harmonic Intervals", O. Zariski on "Equisingular Points on Algebraic Varieties", L. V. Ahlfors on "Kleinian Groups", and S. Bochner on "Analytic Measures on Compact Bohr Groups" are contributions moving near the very frontier of mathematical research, and all demand a highly sophisticated level of mathematical education. The tempestuous development of modern pure mathematics towards ever greater generalization and abstraction coupled with extreme precision is here displayed once more, and much hard work will be required before the gap separating these truly marvellous achievements from all the natural sciences is reduced to manageable proportions.

S. ZIENAU

## METALLURGICAL THERMOCHEMISTRY

### Metallurgical Thermochemistry

By O. Kubaschewski, E. L. Evans and C. B. Alcock. (International Series of Monographs in Metal Physics and Physical Metallurgy, Vol. 1.) Pp. xix+495. (Oxford, London and New York: Pergamon Press, Ltd., 1967.) 75s. net.

REVISED and enlarged, the new edition of this well known book retains the general form and content familiar from the editions of 1955 and 1958. A direct interchange in the previous order of the fourth and fifth chapters, however, now emphasizes the book's dual character. For it essentially comprises two separate but related monographs: the first provides an introduction to the principles and practice of applied thermochemistry, and the second is a convenient collection of thermochemical data relevant to metallurgical problems.

The concise survey of important basic principles and relationships presented in the first chapter has been slightly extended. With the aim of providing a clearer and more logical presentation, occasional modifications have been made in the division and order of the material and in the treatment of some concepts. Brief presentations of some interpolation formulae and atomistic solution models are now included. The latter provide an improved introduction of the concepts of Raoultian, Henrian and regular solution, but the treatments of spinodal decomposition and order-disorder appear somewhat out of context and are insufficiently developed to be of great value.

Although slightly shortened, the chapter surveying experimental methods still provides a comprehensive and once more up to date survey of techniques. Again minor

rearrangements have been made, as, for example, in adopting the contemporary classification of calorimeters as isoperibol, isothermal or adiabatic in character; the newer applications of high temperature adiabatic calorimetry, microcalorimetry and fluorine bomb calorimetry are noted. Developments in the techniques for the measurement of vapour pressures and the extensive application of solid oxide electrolytes for measurements of e.m.f. are also reflected in the review.

Least changed is the chapter dealing with the estimation of thermochemical data, but brief mention is now made of more recent attempts at the empirical estimation of entropies and of the relation of electronegativity to heats of formation.

The pedagogically invaluable fourth chapter, which provides worked examples of the thermochemical treatment of metallurgical problems, has been expanded from eight to thirteen examples. Among the new examples are calculations pertaining to the extraction of nuclear and other metals, the evaporation of ceramic materials, and metal-refractory equilibria at very high temperatures. These and the modified examples of equilibrium diagram calculation appropriately reflect the current and developing interests of metallurgists and demonstrate the importance of thermochemical studies in these fields.

As would be expected after an interval of nine years, perhaps the greatest changes are to be found in the collection of thermochemical data. This monograph within a monograph has been brought up to date (1965) and now runs to 183 pages and lists 661 references to original publications or other reviews of data. The intense experimental activity of past years has resulted in the revision of many of the previous values; a considerable amount of additional information, some from unpublished work, is also incorporated.

The publication of this fourth edition will be appreciated by workers in the field who have come to regard "Kubaschewski" as their normal first source of information on experimental techniques and available thermochemical data. By its clear demonstration that metallurgical thermodynamics is a challenging experimental science, providing a powerful tool for the treatment of real problems, it will also continue to assist in convincing further generations of students that the fundamentals and applications of thermodynamics are subjects meriting their earnest attention.

JOHN N. PRATT

## FUROPYRANS AND FUOPYRONES

### Fuopyrans and Fuopyrones

By Ahmed Mustafa. (The Chemistry of Heterocyclic Compounds: a Series of Monographs.) Pp. xii+376. (London and New York: Interscience Publishers, a Division of John Wiley and Sons, 1967.) 135s.

THE publication of a book concerned with the chemistry of oxygen heterocyclic compounds is always very welcome, especially when it fills an interesting and well defined gap in the chemical literature.

The plant phenols are a group of compounds of great interest to certain organic chemists, some of whom give a prominent position to naturally occurring products which have the fuopyrans and fuopyrones as parent compounds. Knowledge of these and related compounds has developed through the structural determinations of products obtained from plants and plant extracts with certain intriguing properties such as their use as an aid in catching fish or as medicinals and insecticides.

The chapters of the book all follow the same general pattern, starting with an introduction to a specific topic followed by a mention of the chemistry of a number of naturally occurring compounds. Accounts dealing with the determination of structure of such compounds are very concise, but include all the relevant degradation

steps and chemical properties of the original compounds and their degradation products. In fact, in a number of cases, the expressed evidence for the structure of a particular naturally occurring compound is a précis of the original paper. This presentation of the information gathered from an investigation is very useful to a researcher working in related fields and may save time when he wishes to consult the literature. Quite frequently the physiological activity of compounds is emphasized, and a brief reference is made to the biosynthesis of furocoumarins. Adequate coverage is given to the physical properties of compounds. Chapters deal with the chemistry of the furocoumarins, furochromones, furoxanthones, furoflavones, furoisoflavanoids and chromanochromanones (the Rotenoids) in some detail, giving an extensive background knowledge to anybody interested in these topics. In reviewing a book of this type it is very difficult to single out any particular item for special reference, because the number of compounds mentioned is so very large and nearly all of them are treated with the same degree of importance.

It is easy to see that a great deal of work and endeavour has gone into producing this excellent book and it will without doubt find a place in all chemical libraries. This book provides a useful summary of information which will be of great value to research workers undertaking investigations in the oxygen heterocyclic field. The layout of the book is very good and it is easy to praise the excellent diagrams and tables, which are a great help to the reader. In mentioning the inclusion of the more than adequate number of references, it is worth drawing attention to the fact that every effort has been made by the author to include papers indexed by *American Chemical Abstracts*, up to and including 1964, and subsequent papers in the more important journals up to December 1965.

R. LIVINGSTONE

## SORTING STEROIDS

### The Gas Liquid Chromatography of Steroids

Edited by J. K. Grant. (Memoirs of the Society for Endocrinology No. 16.) (Proceedings of a Symposium held at the University of Glasgow on April 4-6, 1966.) Pp. viii + 294. (London and New York: Cambridge University Press, 1967.) 70s. net; \$13.50.

THIS further edition in the series of Memoirs of the Society for Endocrinology contains the sixteen papers (one as an abstract) presented at the symposium on the "Gas Liquid Chromatography of Steroids" and also the verbatim report of the subsequent discussions. The stated purpose of the symposium was to bring together the European workers in the steroid field to discuss and assess the present position of gas liquid chromatography and to consider new techniques to be used in this field and also in conjunction with it. Some of the speakers were not working on steroids and so it was hoped that their contribution would prove both critical and provocative. As the editor states in the preface, however, more was gained in informal rather than formal discussion and, as a result, such benefit is not recorded. As was to be expected, the standard of papers is, on the whole, high.

The first three papers deal mainly with the basic technical problems of gas liquid chromatography and include an excellent discussion of the characteristics of capillary columns, as well as a useful and informative description of the handling of micro-litre quantities. Solutions to some of these basic problems are proposed and, while most are acceptable, perhaps it is a little unreasonable to hope that "instrument manufacturers will improve the design of all their Chromatographers" (page 6—an unfortunate transposition).

There follows an excellent paper on the conditions required for the separation of steroids by this technique.

This is a very condensed and precise contribution which deals with such aspects as the effects of column and column packing, alterations in the stationary phase, the preparation of and the effects of derivative formation and the relationship between the structure of steroids and their behaviour when subjected to gas liquid chromatography.

The principles of the systematic analysis of steroids are then considered briefly, with references to the practical details already published. The results of the application of such a scheme to the study of free and conjugated steroids in human placenta are of considerable interest and the scheme itself indicates the amount of chemical manipulation required before such extracts can be applied to gas liquid chromatography columns. The need for this preparation is borne out very well in subsequent papers on determination of oestrogens, the use of electron capture in the ultramicro detection of steroids and the fractionation of steroids before gas chromatography. The combined use of an electron capture detector with heptafluorobutyrate derivatives of steroids appears to offer greatly increased sensitivity and may well lead to the greater use of these chromatographic techniques in steroid analysis.

The many aspects of the quantitative determination of steroids are dealt with very adequately and this paper underlines the great care that is required before useful results can be obtained.

The estimation of cortisol and prednisolone and the use of haloalkylsilyl ether steroid derivatives are discussed in subsequent papers, and also the problems of investigating such complex mixtures as the metabolites of plant sterols in faeces.

Techniques, such as mass spectrometry and those involving radiochemistry, which are less commonly used in steroid gas liquid chromatography are the subjects of the following three papers. It is perhaps unfortunate that only an abstract is given of one of these papers, for its inclusion would have afforded an opportunity to evaluate the relative merits of the discontinuous and the continuous isotope counting techniques.

The organizers of the symposium are to be congratulated on the success of their meeting and this book is a useful addition to the literature.

D. B. HORN

## CELLULAR ORGANIZATION

### Molecular Insights into the Living Process

By David E. Green and Robert F. Goldberger. Pp. xii + 420. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 78s.

THE authors describe this popular account of molecular biochemistry and cellular organization as being written in a narrative style. It soon transpires, however, that this amounts to serving the molecular "meat" in an anthropomorphic "gravy". Thus the reader is asked to admire "Nature as a brilliant chemist" or "Nature's exploitation of transition state chemistry"—banalities which neither improve the literary flow nor aid the understanding. The authors' own uneasiness about this approach has unfortunately only prompted them to emphasize a Darwinian view of the evolution of molecules which is surely misapplied and will undoubtedly add to the general confusion about this subject.

The central theme of this book, as might be expected, is contained in a ninety page account of the mitochondrion and electron transport system (energy transduction) and the structure and properties of cell membranes. The descriptions are clear and the accompanying diagrams and electron micrographs are good. It does not matter that the ultimate location of enzymes within the mitochondrion is still a subject of some controversy and may require some reappraisal in the future.

Unfortunately, the remainder of the book is very patchy in quality. The opening chapters augur well with an

account of the fitness of elements and molecules for their roles in living systems, although the functional roles of nitrogen, oxygen and sulphur might have been considered as a contrast to the structural role of carbon. Perhaps more disturbing are the decisions to commit a description of the hydrogen bond to a footnote and omit any account of pH and ionization phenomena, which result in much of the subsequent account of proteins and enzymes, in particular, seeming rather unrealistic.

As the authors state, enzymes play a central part in all biological processes. The clarity of exposition of what enzymes are and how we think they work is a needle test of any elementary treatment. *Molecular Insights* . . . does not come out well. A confusion between the structures of fumaric and maleic acid unhappily opens a general account of the properties of enzymes, which neglects to explain the concept of the active site and provides an inadequate background for the discussion of enzyme control (illustrated by the over-complex phosphorylase system) which follows. An attempt to explain the mechanism of catalysis by chymotrypsin fails largely because of small, confusing diagrams (how beautifully this can be presented is shown by the large, clear diagrams by Hartley in *Structure and Activity of Enzymes*). Understanding is not helped by a text statement that two histidines are involved while only one is shown in the diagrams. A later account of the acetokinase reaction is easier to follow but again the accompanying diagrams are much too small.

Coenzymes and prosthetic groups are treated in a fairly conventional way, but emphasizing the functional atoms of each molecule, and the section concludes with an interesting discussion of the chemistry of reduction of DPN<sup>+</sup> (the recommendations of the International Commission on Enzymes are not followed) although not everybody would agree that the carboxamide group plays no part in the process.

Consideration of cell energy processes begins with a chapter on bioenergetics which leans heavily on the "high energy bond"—a concept which even if ultimately explained is better avoided. Surely it is no more difficult to explain at the outset that forming the structures of some molecules requires considerable energy, most of which can be released again when the molecule is broken down, rather than baldly stating that the energy is held in the bond and leaving the reader to puzzle over why some molecules can have such bonds and others cannot. The more rational nature of this approach would have benefited the subsequent discussion in which various reactions of ATP are considered.

The nucleic acids and protein synthesis are not well handled. A diagram of the cytosine-guanine base pair shows only two hydrogen bonds and, in contrast to the mitochondrion, the structures of tRNA and the ribosome are completely ignored while the function of the latter in simultaneously binding the messenger and tRNA only emerges in a later discussion of methods for determining the genetic code. The diagrams at this point are poor and confusing. In contrast, a consideration of the extent to which the amino-acid sequence of a protein determines its three-dimensional structure is followed by a stimulating discussion of the problems involved in the biosynthesis of organelles which loses none of its impact for being, in part, outdated by the march of recent scientific events.

The twelfth chapter, a good general account of control mechanisms, is significant for the return to sanity in presenting biological ideas in a scientific manner and underlines the difficulties in understanding how such complex cellular processes evolved. This is followed by a particularly lucid and commendable account of the relationship between biochemistry and disease. Beginning with a simple genetic lesion, haemoglobin S, examples of increasing complexity are considered ending up with myocardial infarction. Each is analysed to show how complex physiological processes may be described in terms of their contributing biochemical components, an

understanding of which may ultimately lead to successful combat of the disease. The theme is continued by a chapter on the use and design of drugs for therapeutic purposes.

The book concludes by enumerating the biochemical features common to all forms of life and discussing the problems involved in the evolution of even the simplest functional cell and how future research might fruitfully be directed towards improving our understanding of organization at the molecular level.

This book is intended as a unified work to be read and appreciated as a whole. Undoubtedly, most students and many teachers would benefit from the diversity of modern ideas presented, for the most part, in an attractive and palatable way. It is a pity that the inadequate diagrams and poor content of some sections preclude its unqualified recommendation.

D. C. WATTS

## ALL ABOUT THE BROWN TROUT

### The Trout

By W. E. Frost and M. E. Brown. (The New Naturalist.) Pp. 286 + 46 plates. (London: William Collins, Sons and Co., Ltd., 1967.) 25s. net.

In the authors' preface it is stated that "We have tried to avoid the anglers' approach and equally that of the experimentalist and to present a true picture of the brown trout and how it lives in its complex environment". The book is certainly a most readable account, and will be of interest and use to anyone who wishes to know about the brown trout. It must be emphasized that the book deals with the brown trout, and the sea trout is given a very cursory treatment. Perhaps "The Brown Trout" would have been a more appropriate title.

The first chapter deals with the anatomy and physiology of the trout, and works through the various aspects of normal body function. Reproduction is discussed fully in the fourth chapter and behaviour in the eighth chapter. In some ways this first part of the book is a disappointment, because much of the information is so general that it applies to almost any species of bony fish. The treatment is superficial for the expert, and relatively unstimulating for the lay reader.

The other nine chapters are much more stimulating, indeed in some ways it might have been better if the book had started here. The second chapter discusses the taxonomy, and emphasizes the fact that the "many species" of trout described from continental and British waters belong to the one polytypic species *Salmo trutta* L. Closely related species are briefly described. In the third chapter the distribution of the trout is indicated. On page 55 six sub-species recognized by L. S. Berg are listed, but unfortunately the reader is not informed of the characters used to separate these. In view of the emphasis placed on the one polytypic species in the previous chapter it would have been interesting to know this. In addition, it is not stated when Berg arrived at these conclusions and the English translation of the fourth edition of his book<sup>1</sup> gives a rather more complex account.

The fourth chapter describes in detail the life history, gonad development, spawning migrations, spawning and development of the egg, alevin and fry stages. It is concluded with a consideration of the length of life and ultimate fate of the trout. The authors note that the trout has a natural term of life, and individuals which exceed this are rare, although the effective causes of death have not been investigated.

Age and growth form the subjects of the next chapter, describing the Petersen method for ageing fish, use of tagging and the reading of bones and scales. The structure and use of the scales for age determination are dealt with in detail and are well illustrated by photographs. The back calculation of lengths from scales is explained fully, and

the various means of expressing growth patterns are discussed. Specific growth rate is considered the most useful form of expression of these data and Appendix V gives the procedure for the calculation of the specific growth rate. Appendix VI lists specific growth rates of brown trout from various waters in the British Isles and some of these data are duplicated in Table 7 (page 101).

The heredity of the trout is considered in the sixth chapter. The trout is not a convenient subject for genetical experiments because it takes two years or longer to mature and then they breed only once a year. The studies of Alm<sup>2</sup> and Donaldson and Olson<sup>3</sup> are correctly stressed. The chapter concludes with a short section on hybrids.

The longest chapter in the book considers the physical environment. The topographic features are described and the vegetation and fauna associated with each type of environment listed. The reasons for the occurrence of trout in particular types of water are discussed. Climate is related to the annual cycle of events in the life of the trout, and the presence of an internal physiological rhythm in trout kept in a constant temperature and light intensity for a constant number of hours each day is noted. The effect of the introduction of trout to the Antipodes is also discussed in this connexion. The effects of light, temperature and water chemistry on growth of the trout are given and the chapter concludes with a consideration of the results of chemical fertilization of acid waters.

The authors emphasize in the eighth chapter that despite many records there are great gaps in our knowledge of the food of the trout. Figure 22, Tables 22-27, 29, 31 and 32 and Appendix VII compare the food of trout with the bottom fauna, show seasonal feeding, bottom fauna, vegetation and associated fauna, fauna at different depths in lakes and in rivers of increasing hardness. Unfortunately, the species of animals involved are expressed in the form "Caddis l., Mayfly n., Molluscs, snails," and so on. I am inclined to wonder if data shown in this fashion have serious scientific value. It is convenient for the lay reader, but surely the generic if not specific names of the animals could have been included? In addition, there is no discussion of the methods used for the analysis of the stomach contents of fish. Some reference to a critical review, for example that of Hynes<sup>4</sup>, would have been appropriate.

The biological environment is considered in the ninth chapter, and topics such as competition, territorial behaviour and population density are discussed. Inter-specific competition between trout and other salmonids is considered, but the authors state that almost nothing is known from British waters with the exception of the relationship between trout and char in Windermere. It is noted that such studies have been carried out in Norway and Sweden, but these receive no further comment. It would have been appropriate that at least some of these works were discussed, for example those of Nilsson<sup>5</sup>.

A rather inadequate section on parasites concludes the chapter on the biological environment. The authors comment that rather little is known about the effect of parasites on wild trout. This is essentially correct, but no reference is made to any of the work which has been carried out on the parasites of natural populations of brown trout in Continental Europe, the Soviet Union, or even in the British Isles (see, for example, Thomas<sup>6,7</sup>). There is a further adverse criticism about this section, and that is that only generic names of the various parasites are given, and only some members of these genera infect trout.

The final chapter is entitled "Trout and Man" and gives a short account of trout fishing, pollution, management of trout fisheries and improvement of the environment.

There are eight appendices dealing with the routine examination, age and growth determination from scales, data on brown trout from rivers, lakes, the calculation of specific growth rates, specific growth rates from various waters in the British Isles, examination of stomach con-

tents and a list of waters for which data on total hardness are available.

There is a list of 170 references, and a further ten authorities were quoted in the book, but have been omitted from the list. Nine authorities quoted in the text with dates are given different dates in the list of references. Frequently in the text an authority was quoted without indicating the date, a procedure which renders it difficult to refer to the original paper if more than one is listed for that person. On page 196 Jones is referred to, without indication whether J. W. Jones or J. R. E. Jones is meant. The index, however, confirms (page 280) that the work of J. R. E. Jones is being quoted. A similar comment applies to the mention of Berg on page 197, although here the context makes it clear which authority is being quoted.

The plates and figures which illustrate the book are of good quality. The index is useful and is mainly accurate. *The Trout* is, despite a few adverse comments, a very useful book. The authors are to be congratulated on writing it in such a manner that it will be of interest to layman and scientist alike. I must emphasize that in reality the book only summarizes our knowledge of the brown trout, because the sea trout receives a very cursory treatment. It is also relevant to note that the book does not always include or do justice to foreign work on the biology of the trout. Nevertheless, it is excellent value and can be recommended.

## MAN AND PLANT

### Plants and Archaeology

By Geoffrey W. Dimbleby. Pp. 187 + 23 plates. (London: John Baker, 1967.) 50s. net.

PROFESSOR DIMBLEBY's book pleads a cause. He first asks those who excavate to ensure that plant remains do not escape notice, and then asks those who interpret the discoveries to do so positively and imaginatively. The book has three parts—a survey of the many diverse and ingenious uses to which man has put plants and their products, an account of the ways in which different parts of plants may be preserved and discovered, and an indication of the information that may be derived from the discoveries. One hundred and sixty books and papers are referred to, but the text is aimed at the general reader. A similar concession is not made by the illustrations, which are mainly microphotographs of very high standard of wood, fibres, seeds and pollen, more appropriate for study at the laboratory bench than in the domestic armchair.

In addition to calling for more information, Professor Dimbleby drives home in a very valuable way the profound need to separate those vegetational changes which are caused by climatic change alone, from those in which the hand of man may have been concerned. Gone are the days when we could happily rattle off as a climatic sequence Boreal, Atlantic, Sub-boreal, Sub-atlantic. Iversen and Troels-Smith have demonstrated the profound effect of the Neolithic farmer. The book cites ample evidence for Mesolithic influence on vegetation, and refers to West's tantalizing suggestion of Palaeolithic forest clearance at Hoxne.

The author pays well-merited tribute to Helbaek's work, both in northern Europe and more recently in the near East, on cereal plants and the weeds which accompany them in cultivation. Professor Dimbleby notes that the carrying of crop seed by migrating groups has been an important factor in weed distribution. Detailed

work on the first appearance of specific weeds in different areas might well throw light on the migration of different culture groups. Like King Alfred and the cakes, those who in prehistoric time were given the task of heating grain to prevent its germination during storage sometimes neglected their task, so that the mass of grain became charred and had to be jettisoned. Study of samples of such charred grain often reveals surprising differences. Sometimes the samples are full of many different weed seeds, sometimes they are remarkably clean. Different agricultural practices must lie behind such differences.

Professor Dimbleby deserves our thanks for a stimulating book.

G. F. MITCHELL

## PSYCHIATRIC SUMMING UP

### The State of Psychiatry

Essays and Addresses. By Aubrey Lewis. Pp. ix + 310. (London: Routledge and Kegan Paul, Ltd., 1967.) 63s. net.

### Inquiries in Psychiatry

Clinical and Social Investigations. By Aubrey Lewis. Pp. vii + 335. (London: Routledge and Kegan Paul, Ltd., 1967.) 63s. net.

IN these two volumes, published at the insistence of his present and former pupils, Sir Aubrey Lewis has collated the pick of his contributions to the literature of psychiatry during the past forty years. For once, the term "literature" is not inappropriate: in many of these papers, the writer shows a turn of phrase and a relish for the unfamiliar yet precise word calculated to excite the envy of a Vladimir Nabokov. This aesthetic element is apparent not only in the first volume, sub-titled "Essays and Addresses", but also in the second where it informs the writer's imaginative insight into the phenomena of mental illness—as in the earliest paper, which deals with "The experience of time in mental disorder". This penetrating clinical report has an added significance today because distortion of the sense of time is one of the striking characteristics of intoxication with cannabis or LSD.

The major work in the second volume is undoubtedly Sir Aubrey's massive clinical and prognostic study of depressive states, a study which led him to conclude that the customary practice of categorizing depression as either "endogenous" or "reactive" was an erroneous oversimplification. Curiously enough, more than thirty years after the publication of these papers, the illusory dichotomy still holds the field, although empirical studies designed to test its validity have shown conflicting results. When one re-reads Sir Aubrey's classic paper, one finds that although he suggests that the term "reactive depression" should be done away with (volume 2, page 112) he follows this almost immediately by the suggestion that in each case an assessment should be made of the degree to which reactive processes or endogenous factors enter into the illness. This suggestion, in turn, is not advanced directly but only by endorsing the words of a German neuro-psychiatrist. Here, and again in the two papers on obsessional illness, we encounter the paradox of Sir Aubrey's clinical teaching: he shows a keen perception of the subtleties of the phenomena, but is so conscious of the limitations of present knowledge that he finds it almost impossible to commit himself to a firm theoretical formulation.

This acute awareness of the complexity of psycho-physiological phenomena and of the paucity of definite knowledge about their underlying processes was what characterized his teaching. One might say that he specialized in making trainee psychiatrists realize how little they knew: but he also demonstrated, in his own work and in his discussions of current research, how this great continent of ignorance could be explored, surveyed, measured and conquered piecemeal.

His first volume contains three concise and concen-

trated articles summing up his views on the teaching of psychiatry, and also a number of papers addressed to a wider audience. Here, his two major interests are apparent: first, the history of ideas about mental disorder and the relationship of these ideas to the contemporary social and intellectual climate in earlier periods: and second, his tireless concern to promote a spirit of true scientific empirical verification in contemporary psychiatric research. If such research has a keener cutting edge today than forty years ago—as few would question—this is because its tools have been honed by the whetstone of Sir Aubrey's intellect.

G. M. CARSTAIRS

## OBITUARIES

### Dr Ann Horton

ANN CATHERINE HORTON (née Davies), who died in Cambridge on July 15, was the first woman to be appointed to the lecturing staff of the Cavendish Laboratory. She was born in London in April 1894, the daughter of Robert Davies, merchant tailor, and studied physics at Royal Holloway College where she took her B.Sc. in 1915 and her D.Sc. in 1922. Most of her published work, comprising about twenty-five papers in the *Proceedings of the Royal Society* and elsewhere appearing between 1919 and 1936, were carried out at the College in co-operation with Professor F. Horton, whom she married in 1939. The most important of these papers were concerned with radiation from and ionization potentials of the rare gases; the work emphasized the importance of a high degree of purity in gases under study, and in the years following Bohr's theory of stationary states contributed to its full verification. Her last paper "The Production of Radiation and Ionization from Helium Atoms by Potassium Positive Ions" reports work which she carried out in the Cavendish Laboratory, published by the Royal Society in 1936.

After holding a position as staff lecturer at Holloway College, Miss Davies was appointed fellow and lecturer in physics at Newnham College, Cambridge, a position she held until 1957; she was vice-principal of the college from 1936 to 1946. From 1935 until 1961 she was a university lecturer in physics and continued demonstrating to Part I classes until a few months before her death. She had many outside activities. For instance, she was a member of the Trustees of Homerton College, Cambridge, and in this capacity was particularly interested in the problems a training college has in producing good science teachers with an experimental approach to their subject. She was a member of the Council of New Hall and at a time when several groups in Cambridge had been working to secure more places for women students in the university she played a great part in formulating the practical policy, and her moderation, good sense and willingness to listen played an important part in the foundation of the college in 1954.

When her main interests had moved from original research to teaching and planning, she never lost her independent approach to the sort of problems which always arise in an active laboratory. When an experiment in the practical class gave unexpected results, or when students wanted to know something more than the working manuscript had told them, she was always ready to explore it with them, whether it concerned an unevenly loaded strip, a zone plate with badly drawn zones or a radioactive source with unexpected lifetimes. Her wide experience, her readiness to tackle difficulties and her patience in giving help where help was needed were of value not only to successive generations of students but also to her academic colleagues and the assistant staff. It would be fair to say that the unassuming way in which she took her place and her full part in a laboratory which had not previously had women lecturers made it easier for those who came after her.

## University News:

DR C. KAPLAN, at present head of the Virus Vaccine Department in the Lister Institute of Preventive Medicine, has been appointed professor of microbiology and will succeed Professor B. C. J. G. Knight as head of the Department on his retirement in September 1969. Professor V. H. Heywood, at present professor of botany in the University of Liverpool, has been appointed to the chair of botany in succession to Professor T. M. Harris.

## Reading

## Appointments

DR E. V. D. GLAZIER has been appointed director of the Royal Radar Establishment at Malvern. Dr Glazier took his BSc in 1935 and his PhD, also in engineering, in 1942. He has worked in the GPO and the Signals Research and Development Establishment. Since 1959 Dr Glazier has been at RRE and his appointment as director took effect from September 1. His predecessor Dr Macfarlane now holds the post of controller of research in the Ministry of Technology.

DR BORIS GRINBERG has been appointed director of the International Atomic Energy Agency's Division of Research and Laboratories, in succession to Dr Garman Harbottle, who is returning to Brookhaven National Laboratory.

DR JAMES R. HEIRTZLER, at present senior research associate at Columbia University's Lamont Geological Observatory, has been appointed director of the university's Hudson Laboratories in succession to Dr Alan Berman, who has been appointed director of research at the US Navy's Naval Research Laboratory.

## Announcements

PROFESSOR J. BLAMONT, scientific and technical director of the Centre National d'Etudes Spatiales and director of the Laboratoire d'Aéronomie du Centre National de la Recherche Scientifique, has been awarded the Guggenheim international astronomical prize.

THE second Jansky Lectureship has been awarded to Professor Jan H. Oort, director of the Leiden Observatory, The Netherlands, and he will deliver a lecture entitled "Large-scale Distribution and Motion of Hydrogen in the Galaxy" on November 29 at Gilmer Hall Auditorium, Charlottesville, Virginia.

PROFESSOR A. CORRADETTI, director of the Department of Parasitology and Entomology, Istituto Superiore di Sanità, Rome, and Dr Clay G. Huff, chief parasitologist at the Naval Research Institute in Washington, have been elected honorary fellows of the Royal Society of Tropical Medicine and Hygiene.

APPLICATIONS for a Meres senior studentship for medical research are invited by the Council of St. John's College, Cambridge. The candidate must be a university graduate, and will be elected for a period of not less than one year or more than three years. Further information can be obtained from the Master, St. John's College, Cambridge.

A MEDAL and award of one hundred guineas is being offered by the Royal Agricultural Society of England for research work carried out in the United Kingdom which has proved of benefit to agriculture. Recommendations for this award can be made by heads of university departments, research stations and institutes and other research organizations, and further information can be obtained from the Secretary, Royal Agricultural Society of England, 35 Belgrave Square, London, SW1.

A NUCLEOTIDE Chemistry Group of the Chemical Society is being formed in order to encourage the discussion of the chemistry of nucleosides, nucleotides and nucleic acids. Membership of the group is not confined to fellows of the society and further information can be obtained from

Dr A. S. Jones, The Chemistry Department, The University of Birmingham, P.O. Box 363, Birmingham, 15.

THE inaugural meeting of the Fisheries Society of the British Isles is to be held at the Meeting Rooms of the Zoological Society of London on Saturday, October 21, at 2.30 p.m. Further information can be obtained from Mr. Lionel E. Mawdesley-Thomas, Fisheries Society of the British Isles, Huntingdon Research Centre, Huntingdon.

## Meetings

HIGH Pressure Engineering, September 11-15, Imperial College of Science and Technology (Mr R. Glynn, Head of the Conference Department, The Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, SW1).

MOLECULAR Model Building, September 18-29, State University of New York at Buffalo (Mrs W. J. Browne, Laboratory of Molecular Biophysics, Department of Zoology, University of Oxford, Oxford).

CONCRETE Roads for the Future, September 20, London (The Operations Department, The Concrete Society, Terminal House, Grosvenor Gardens, London, SW1).

AMORPHOUS and Liquid Semiconductors, September 28-October 3, Bucharest (Professor R. Grigorovici, Institute of Physics of the Academy, Calea Victoriei 114, Bucharest).

ENERGY Sources for Space Power, October 2-6, Brussels (Office of the Director Plans and Programmes, AGARD, 64 Rue de Varenne, Paris).

CROP LOSSES: Evaluation of Field Losses caused by Pests and Diseases and of Factors affecting Epidemics and Outbreaks, October 2-6, Food and Agriculture Organization, Rome (Dr L. Chiarappa, Crop Protection Branch, FAO, Viale delle Terme di Caracalla, Rome).

DIELECTRIC Properties of Biological Macromolecules, October 3, Queen Elizabeth College (Dr E. H. Grant, Queen Elizabeth College, Campden Hill Road, London).

# CORRESPONDENCE

## Unfair to Aristotle

SIR,—If a dead man's reputation is wrongly and needlessly attacked, it is up to the man's friends to defend him, and if the man has been dead for more than two thousand years, the friends must be posthumous ones. In view of this, may I comment on the statement in the review of a translation of Albertus Magnus's *Book of Minerals* (*Nature*, 215, 443; 1967), that Aristotle's doctrine prevented true scientific advance based on observation for a thousand years?

In the first place, surely the writer does not really believe that Albertus was influenced by Aristotle; if his book was no advance—of no value—why translate it, or review it once translated?

In the second place, Aristotle's doctrines were not well known through most of the Christian era until the tenth or twelfth century. Until then, Greek influences were more neo-Platonic than Aristotelian; indeed, only the logical treatises were known until about the tenth century. People could not be under the influence of doctrines which they did not know.

Yours faithfully,

H. L. ARMSTRONG

Department of Physics,  
Queen's University,  
Ontario.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Sunday, September 10—Tuesday, September 12

BOTANICAL SOCIETY OF THE BRITISH ISLES, in association with the LINNEAN SOCIETY OF LONDON (at the Hartley Botanical Laboratories, the University of Liverpool)—Conference on "Modern Methods in Plant Taxonomy".

Monday, September 11

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr R. C. Teasel and Mr R. D. Miller: "Characteristics of New Ignition Systems to Improve Engine Performance".

Monday, September 11—Friday, September 15

INSTITUTION OF MECHANICAL ENGINEERS, APPLIED MECHANICS GROUP (at Imperial College of Science and Technology, London, S.W.7)—Conference on "High Pressure Engineering".

Tuesday, September 12—Wednesday, September 13

BRITISH OCCUPATIONAL HYGIENE SOCIETY (in the Clement Stephenson Theatre, School of Agriculture, University of Newcastle upon Tyne), at 9.30 a.m. daily—Conference on "Hazards in Docks and Shipyards".

Friday, September 15—Saturday, September 16

SYSTEMATICS ASSOCIATION (in the Department of Botany, The University of Birmingham, Birmingham)—Symposium on "Chemotaxonomy and Serotaxonomy".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

DEMONSTRATOR or SENIOR DEMONSTRATOR in the DEPARTMENT OF PURE MATHEMATICS—The Registrar, The University, Liverpool, 3, quoting Ref. RV/158/N (September 15).

LECTURER (with qualifications in physiology or applied physiology) in PHYSIOLOGY in the Department of CHEMISTRY AND BIOLOGY—The Deputy Registrar (Personnel), University of Wales Institute of Science and Technology (Designate), King Edward VII Avenue, Cathays Park, Cardiff, quoting Ref. NAT88 (September 16).

SCIENTIFIC ASSISTANT in the DEPARTMENT OF MEDICINE for experimental work of a physiological character on the lung—The Registrar, The University, Sheffield, 10 (September 16).

TUTORIAL RESEARCH STUDENT (graduate) in PHYSIOLOGY for duties which include the supervision of laboratory classes—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (September 16).

SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER, ZOOLOGIST (with a good honours degree combined with approved postgraduate experience) at the Nature Conservancy Scottish Headquarters, Edinburgh, to study deer behaviour and movements—The Natural Environment Research Council (E), State House, High Holborn, London, W.C.1 (September 22).

CHEMIST (with a degree or equivalent with interest in soil, applied or analytical chemistry) to work in the MICROBIOLOGY SECTION on the evaluation of effects of herbicides on chemical activities of the soil affecting soil fertility—The Secretary, A.R.C. Weed Research Organization, Kidlington, Oxford, quoting Ref. 15/67 (September 23).

JUNIOR RESEARCH ASSOCIATE (graduate with an honours degree in zoology) in the DEPARTMENT OF ZOOLOGY to work on the taxonomy of trichopteran larvae—Dr G. N. Philipson, Department of Zoology, University of Newcastle upon Tyne (September 27).

LECTURER in BIOCHEMISTRY in relation to veterinary studies—The Secretary of the University Court, The University, Glasgow (September 28).

CHAIR OF PHYSIOLOGY in the Faculty of Medicine, University College of Rhodesia, Salisbury—The Registrar (RS), University of Birmingham, P.O. Box 363, Birmingham, 15 (September 30).

EXPERIMENTAL OFFICER (with H.N.C. or equivalent qualification, and a good knowledge and practical experience of basic electronic circuit techniques using both vacuum-tube and solid-state devices) in the DEPARTMENT OF ELECTRICAL AND ELECTRONIC ENGINEERING—The Registrar, The University, Nottingham (September 30).

LECTURER (veterinary graduate) in VETERINARY STATE MEDICINE and PUBLIC HEALTH in the DEPARTMENT OF ANIMAL HEALTH, Royal (Dick) School of Veterinary Studies—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (September 30).

RESEARCH FELLOW/ASSISTANT to work on a study of the response to vibrations and ride motions in transport vehicles—The Registrar, University College of Swansea, Singleton Park, Swansea, South Wales (September 30).

SENIOR LECTURER or LECTURER in ZOOLOGY at the University of Natal, Pietermaritzburg—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, September 30).

CHAIR OF ANTHROPOLOGY at the London School of Economics—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 3).

LECTURER in ANATOMY at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 13).

SENIOR LECTURER in CHEMICAL ENGINEERING at the University of Cape Town—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (October 15).

CHAIR OF VETERINARY PHYSIOLOGY at the Royal Veterinary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 25).

LECTURER in the DEPARTMENT OF NUCLEAR AND RADIATION CHEMISTRY at the University of New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 30).

GEORGE HOIT CHAIR OF PATHOLOGY—The Registrar, The University, Liverpool (November 7).

SECOND CHAIR OF OBSTETRICS AND GYNAECOLOGY at the University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 30).

BIOCHEMIST (Senior or Principal grade) (with an honours degree in science or its equivalent and considerable experience in hospital biochemistry) in the DEPARTMENT OF PATHOLOGY—The Secretary, Darlington Memorial Hospital, Darlington.

JUNIOR TECHNICIAN (with previous experience in histology and histochemical techniques) to join a small group working on problems of intersexuality in domestic mammals—The Secretary, Paediatric Research Unit, Guy's Hospital Medical School, London Bridge, S.E.1.

PHYSICAL CHEMIST (preferably with research experience in the field of polymer characterization, optical studies or electrical behaviour) to join a group concerned with long-range research into the study of new materials—The Personnel Officer, Arthur D. Little Research Institute, Inveresk Gate, Musselburgh, Midlothian, Scotland.

POSTDOCTORAL CHEMICAL ENGINEER, CHEMIST or PHYSICIST to investigate reactions of hydrocarbon dispersions heated in shock tubes—Professor A. G. Gaydon, F.R.S., Department of Chemical Engineering and Chemical Technology, Imperial College of Science and Technology, London, S.W.7.

POSTDOCTORAL RESEARCH ASSISTANT in the DEPARTMENT OF ZOOLOGY for the study of certain aspects of the biochemistry of oogenesis in Amphibia—Dr H. C. Macgregor, Zoology Department, University of St. Andrews, Fife, Scotland.

RENTOKIL RESEARCH ASSISTANT (graduate or prospective graduate in biochemistry, with a strong interest in animal behaviour) in the DEPARTMENT OF BIOLOGY to undertake a study of the olfactory response of rodents—The Academic Registrar (EMS), Brunel University, Kingston Lane, Hillingdon, Uxbridge, Middlesex.

RESEARCH ASSISTANT in the DEPARTMENT OF ZOOLOGY to work under Dr A. F. G. Dixon on the effects of aphids on tree growth—The Secretary, Department of Zoology, University of Glasgow, Glasgow, W.2.

RESEARCH ASSISTANTS (good honours graduates) in the PHYSICS, CHEMISTRY or ENGINEERING DEPARTMENTS—The Registrar, West Ham College of Technology, Romford Road, London, E.15.

S.R.C. POSTDOCTORAL RESEARCH FELLOW in the DEPARTMENT OF INORGANIC, PHYSICAL AND INDUSTRIAL CHEMISTRY for work on reactions of methylene (CH<sub>2</sub>) and imidogen (NH) radicals, with particular reference to their photofragmentation and reactions in condensed and gaseous phases—The Registrar, The University, Liverpool, 3, quoting Ref. RV/153/N.

SCIENCE GRADUATE to work in a metabolic unit under the Professor of Psychiatry doing full-time research on biochemical aspects of mental disorder—The Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London, S.E.5.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

## Great Britain and Ireland

- United States Department of the Interior: Geological Survey. Professional Paper 575-B: Geological Survey Research 1967, Chapter B. Pp. v+265. (Washington, D.C.: Government Printing Office, 1967.) \$2.25. [137]

## HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.  
The direct postal price per subscription for one or two copies of NATURE each week is:

### \*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire.....£14.0.0 each  
United States of America.....(by air freight).....\$44 each  
Canada.....(by air freight).....\$47.80 each  
Elsewhere overseas by surface mail.....£13.15.0 each

(Charge for delivery by air mail on application)

\*Shorter periods *pro rata*. (Minimum three months.)

### MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

#### 12 MONTHS (52 issues and 4 indexes)

Number of Copies	G.B. & Eire	U.S.A. (by air freight)	Canada (by air freight)	Elsewhere (surface mail)
3-5	Each £13.10.0	Each \$42	Each \$46.00	Each £13.10.0
6-11	£12.15.0	\$40	\$43.60	£12.15.0
12 or more	£12.0.0	\$38	\$41.70	£12.0.0

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)

## HEAD ON THE BLOCK

THE report of the Science Research Council for 1966-67 (HMSO, 6s. 9d.) is a curious mixture of resignation and cheerfulness. Like the best martyrs, the council seems determined to keep its head high and its lip stiff even in adversity. In particular, to judge from the evidence in the report, it has resolved not to cry out with anguish even when outsiders can tell that it is being starved of funds to the point where jobs which need doing cannot be done properly. This, of course, will suit the administrators and, if it comes to that, there is always the possibility that the council has been dealt with fairly in the sharing out of what is called the national cake in the past few months. But that, fortunately for the council, is somebody else's responsibility. Within its own terms of reference, it could usefully have been less diplomatic and more outspoken.

What is the outlook? In strictly financial terms, the immediate future for the Science Research Council and its dependants is not entirely black. For one thing, there is now a measure of financial stability, and the council is right to boast a little about this. After spending several years with the uncertainty of never quite knowing whether forward commitments on research grants would be honoured by the government of the day, the council (backed up by the Council for Scientific Policy) has been able to establish the view that budgets shall be agreed with the Treasury three years or so in advance. It is probably just bad luck that the system should have started operating at a time of financial pressure on public funds, but the result is to make the agreement on forward planning seem, this year, more like an unpleasant boundary condition than a guarantee of peace of mind. In the event, spending is to increase from £34.3 million in 1966-67 to £43 million in 1969-70, which represents an annual increase of just over eight per cent. Compared with the rate of growth elsewhere in the British economy, this may seem more like an explosion than mere growth. This, however, is not the point. The tests which should be applied to the question of whether the council has enough money to spend are much simpler and more specific than that. What needs to be decided is whether it can do what needs doing properly. There are unwelcome signs that it cannot.

In the council's view, the allocations for the years ahead should permit "modest progress". Plainly it has been under some pressure from the three boards which help to make decisions on the allocation of funds and which are said to have "reduced their demands below what they felt was desirable in the interests of science". Sir Bernard Lovell, the chairman of the Astronomy, Space and Radio Board, has been much more outspoken than that. After the publication of

the report he took care to emphasize that, although his own subject of radio astronomy seems to have come off quite well in the share-out, elsewhere people were being forced to make economies within forward plans which they had considered to be inadequate two years ago, when the Science Research Council was first established. And the truth is, of course, that what seems to be the ending of a period of rapid growth has come at a time when all kinds of new demands on the council's finances should have been openly acknowledged. This, after all, is a time when a great many new universities are coming into service, with fresh needs of funds for carrying out research. The time is ripe for a number of new ventures in the physical sciences. Sophistication—which is the euphemism for the increasing cost of doing good work—abounds. And there is a continuing but clamant need for effective steps somehow to realize the pious hopes there have been in recent years that postgraduate teaching would soon come of age in Britain as it has elsewhere. In the long run, it would have done more good if the council had drawn attention more sharply to these and other problems. To promise implicitly, as has been done, not to be a thorn in the flesh of the Treasury in the years ahead is both unnecessary and unwise.

The danger of a stagnation in postgraduate teaching is particularly serious. According to the figures quoted in the report, there was actually a decline in the numbers of new postgraduate studentships awarded by the council, from 1,947 in 1965 to 1,831 in 1966. Given that the council is the chief source of financial support for postgraduate students at British universities, this is an unhappy tendency. It is true that 1965 seems to have been a particularly good year, but this is a field in which it is reasonable to ask that every year should be a good year. The fact that the council has done something to soften the effects of this tendency by introducing a scheme by means of which students can sign on for postgraduate courses and then spend several years in industry before completing a higher degree is a useful innovation, but not strictly relevant to the problem of finding ways of creating a sufficient stock of highly trained young people. This is why it is, if anything, a step backwards that the council has now taken to the dubious expedient of asking that ten per cent of all training awards in physics and chemistry (and half that proportion in other subjects) should be awarded only to people working on problems which are of direct interest to some industrial company. This rule has already led to some unseemly scrambling by academics for somewhat artificial links with industry. Everybody will appreciate the council's wish to find some way of inducing more young people into industrial occupations. At this stage there is no

reason to think that the expedient which the council has hit on is more than an irritating gesture in that direction.

On research grants, penny wise may also mean pound foolish. The council says that lack of funds has forced it to turn away projects which would otherwise have qualified for grants, but, in spite of this, spending on grants has gone up from £7.8 million to £10.2 million. And it will probably do very little harm if the high-flux magnet laboratory and the high-flux beam reactor—both of them potential candidates for houseroom at Harwell—are postponed for a year or so. Those who back the reactor (at a capital cost of £7 million) will be lucky if it is provided with funds by the time the council's next report is out. It is also entirely proper that the proposal to increase the intensity of the proton beam in the NIMROD accelerator has been postponed—indeed it would have been unseemly if the nuclear physicists had pressed hard both for the NIMROD project and for a British contribution to the new CERN machine. Large items of capital equipment seem also to have done well in astronomy and in other related fields. It is particularly pleasing that the Isaac Newton telescope will soon be working, and that there will be some access to the Australian instrument in the seventies. But is it also wise to cut down on grants for high energy physics when there is evidence accumulating of how scientists from Britain make much less use than they might do of central installations such as the CERN machine at Geneva, sometimes for lack of funds? The council is right to boast of what it has done to support biology in the past few years (although its boast in the report is somewhat too reverential), but it would have been splendid if it could have given some real evidence that it is alive to the needs and interests of all the newer universities—even the smaller ones. And what, in any case, about the polytechnics?

All this implies that the council is if anything too modestly unwilling to acknowledge the central position which it occupies in the planning of academic research in Britain. Unlike the other research councils, it is deeply involved in higher education, partly through the research grants and partly through its support of postgraduate students. It has stronger industrial links than the other councils (and there are some passages in the new report which suggest that the council is not entirely sure where it stops and the Ministry of Technology begins). But this, of course, implies that the council could with advantage occupy some valuable ground which has so far tended to stay untenanted—it could play a much more vigorous part in planning the development of science in Britain than has been its inclination in the past two years. This by itself, of course, is no complaint. The council is still only two years old, and it is only now becoming clear what kinds of tasks the Council for Scientific Policy can undertake and what it must leave to others. Yet it is becoming plain that academic science is going quite soon to be as much in need of a strong and independent buffer between itself and the Department

of Education and Science as the universities were in need of the University Grants Committee several years ago. The council could make a good beginning by seeing that it represents in public, not just at committee meetings, any discontents which it may have about the financing of research.

## HOVERCRAFT AHEAD

THESE are happy days for hovercraft enthusiasts. Next month the largest hovercraft yet built will emerge from the works of the British Hovercraft Corporation at Cowes. Within the next few months, work will also begin on a flat strip of fenland north of Cambridge, where the first tracked hovercraft will be built and tested. If appearances are to be believed, the development of hovercraft in Britain is being pursued with vigour. The National Research Development Corporation will no doubt be grateful if the bustle of activity drowns for a time the criticism of the way in which development has been handled in the past.

The NRDC has been responsible for hovercraft since it first backed them in 1957. It set up a subsidiary, Hovercraft Development Limited, to handle research and the issuing of licences to companies wanting to build hovercraft. Research was carried out by a technical group at Hythe, but this was transferred earlier this year to the control of the National Physical Laboratory. Development work was carried out by the companies licensed by HDL. There seems from the start to have been a determination to concentrate the industry in a small number of powerful companies—as recently as 1966, for instance, NRDC was congratulating itself in its annual report on the merger of the two largest licensees, Westland Aircraft and Vickers, into the British Hovercraft Corporation, now the most powerful company making hovercraft in Britain. Most of its £5 million equity (65 per cent) is owned by Westland. The NRDC itself keeps 10 per cent. At the time only one other company (Cushioncraft) had been licensed, but more recently there has been a gradual change of policy on licensing agreements. In February this year, NRDC awarded a licence to Hovermarine, a Southampton company formed to specialize in submerged wall hovercraft, and work started on the first two versions of a sixty-seater hovercraft. The licence was the result of long negotiation, for the company had been formed nearly eighteen months before. This week, NRDC has announced that Vosper Thornycroft is also to be allowed into the market. The basis of the industry is thus becoming broader, although there is no evidence that NRDC has abandoned its scorn of duplication. Elsewhere, both Bell Aerosystems in the United States and Mitsubishi in Japan have negotiated licensing agreements with BHC; although this has been the occasion for some criticism, it was really no more than bowing to the inevitable. Few of the patents on hovercraft exclude other manufacturers, and sales from Britain to the United States would be

particularly difficult without a licensee. The argument is that for each hovercraft Bell and Mitsubishi build, BHC will receive royalty payments and that, if hovercraft establish themselves, there will be enough business for all three.

The British Hovercraft Corporation is hoping that the breakthrough to profitability will be soon. Next month, its first serious attempt to capture a share of the transport market, the *SRN 4*, will be rolled out from the factory at Cowes. (BHC firmly uses aircraft terminology, so that the *SRN 4* will not be "launched"; the Board of Trade, not yet sure how to define hovercraft, is to invent a special category for them.) Although the nine-ton *SRN 6*, which can carry 38 passengers, has been used on regular scheduled services within the British Isles and for pleasure trips from seaside beaches, it is a calm-water hovercraft. *SRN 4*, as well as being nearly twenty times as big, will have to operate in far worse conditions. It will weigh 160 tons, and be capable of carrying 800 commuter passengers, or 256 people and 30 cars at a speed of 70 knots. This is clearly a great advance, but potential buyers are behaving warily. So far, only two have appeared. Hoverlloyd, a Swedish company, has ordered two for a service between Ramsgate and Calais, and British Rail has ordered one. If these two operators are successful, other buyers will undoubtedly come forward.

It is hard to feel as optimistic about another hovercraft project announced last week. Several months after NRDC proposed the idea, the Ministry of Technology approved the construction and operation of a tracked hovercraft in East Anglia. The tersely worded announcement from the ministry gave few details of the project, the broad outlines of which have been established after computer studies and model testing at Hythe. The design provides for hovercars 50 feet long by 10 feet wide, weighing 10 tons and running on a T-shaped reinforced concrete beam 4 feet from the ground. The cars would be propelled by the linear induction motor developed by Professor E. R. Laithwaite at Imperial College, London, and would reach a speed of 300 m.p.h. In order to test these ideas at full scale, twenty miles of fenland north of Cambridge have been obtained on lease from the Great Ouse River Authority, and a track will be built there. The ministry says that the cost will be £2 million over the first two to three years, but nobody seriously believes that will be the final cost. The track alone will cost more—probably £0.25 million a mile for a device of 70 tons. The experiment may well be cheaper, but if 300 m.p.h. is to be reached at least 20 miles of track will be needed. It is hard to see how this could be done for less than £3 million, and then it will be necessary to build a vehicle filled with electronic equipment. By publishing a figure of £2 million, even with the proviso that it will cover only the first few years, the ministry has laid itself open to criticism when, in five or ten years time, the cost turns out to be £5 million or even £10 million.

Certainly it will be possible for tracked hovercraft

to provide a more rapid service than conventional trains or the aircraft now in service. Even allowing for improvements in transport between airports and city centres, a hovercraft travelling at 300 m.p.h. would still be quicker on journeys of up to 600 miles. This assumes that hovercraft would be allowed to operate from city centres, but that is plausible. Hovercraft may be able to compete with aircraft, but this calculation takes no account of the improvements which are possible in conventional train services.

The estimates produced by HDL make tracked hovercraft seem a dubious proposition. Double track would cost about £0.5 million a mile, and one car, seating 200, would cost £420,000. For routes handling fewer than 2 million passengers each year, air travel would be cheaper. At higher densities, the figures begin to look more attractive, but only on routes handling more than 6 million passengers a year would hovercraft be able to offer cheaper transport than trains. The greatest density on any British Railway route in 1965 was 5 million passengers a year, so that there seem at present to be no routes in Britain on which the hovercraft would be cheaper than the trains. The ideal hovercraft route must be one on which the density of traffic makes the idea economically attractive but long enough to make use of the greater speed the hovercraft offers. Nothing in Britain can compete effectively with the Northeast Corridor in the United States as a route for introducing hovercraft. The hovercraft men in Britain may have to turn their sights to Stansted if the Government really decides to make that London's third airport, but that is another matter—political as well as economic.

All this is not to say that hovercraft will never supply an acceptable alternative to conventional systems of transport, but they are obviously more attractive where alternative systems are slow and inconvenient, as with the cross-Channel ferries. Even there, the Channel Tunnel may reduce the amount of traffic carried above the surface. Where existing systems operate at higher speeds and are capable of considerable development, the case for hovercraft looks slim. British Rail, losing £130 million a year on rail services, has been castigated for its reluctance to embrace the hovercraft. In retrospect, it may turn out to have been wiser to concentrate on the improvement of existing services.

## ASK FOR MR JONES

THE British Government is well on the way to making a great muddle of its policies towards the nationalized industries, particularly in fuel and power. The immediate cause of trouble is the announcement two weeks ago of higher prices for the electricity sold to domestic consumers. It has been known since May this year that electricity prices would have to go up, but domestic consumers (who are also usually voters) have not taken kindly to the suggestion that they will have to pay an extra 16 per cent. Mr Richard Marsh, the Minister of Power and the custodian of electricity

prices, only has himself to blame that his holiday in Yugoslavia was cut short by the excitement, and that the Prime Minister has agreed that all future charges levied for products or services by the nationalized industries shall first of all be examined by the Prices and Incomes Board. It does not take a particularly long memory to appreciate that this will bring pleasure to Mr Aubrey Jones, the chairman of the Prices and Incomes Board, for his complaint that the Government should have given him a chance to examine this latest increase of price seems to have been fully vindicated. If things go on like this, people will be wondering who is the Prime Minister—Mr Wilson or Mr Jones.

Although the problem of what prices the nationalized industries should charge may on the face of it seem to be an exceedingly academic issue, the fact that these industries between them are responsible for more than a sixth of the industrial activity in Britain is a sufficient proof that the London School of Economics cannot be left entirely in charge. By what may seem to some to be a pleasing poetic justice, the rules by which the nationalized industries are at present regulated have their roots in the late fifties, when the electricity industry invited the enmity of the Treasury by the size of its capital investment each year in new power stations and transmission plant. In the competition for capital, private industry was starved of funds, and it became apparent that nothing in the original acts of nationalization laid down how much the nationalized industries should seek to earn by way of surplus on their trading. From there it was a short step to the White Paper of April 1961 by means of which each nationalized industry was told to earn a surplus each year defined as a certain percentage of the net capital assets employed. Electricity was asked to shoulder the heaviest burden, presumably but illogically because it was the only one of the nationalized industries to have consistently made a profit in the fifties. Ironically, the chief reason why electricity prices must now be increased is that the industry is hard pressed to raise the whole of the 12·4 per cent of the surplus which is specified.

So should the charges be abolished? This is what a great many people will say when bigger bills come in for payment in the months ahead. The simple answer is that they are indispensable. Just as other kinds of industries must make provision out of their earnings for the depreciation of plant and for the raising of capital, so nationalized industries must keep their books in proper order. In 1965–66, for example, the electricity industry put aside £330 million to cover these charges, and also earned a surplus of £85 million. Taken altogether, these sums of money were 12·6 per cent of the net capital employed, or more than enough to satisfy the industry's statutory obligation. Yet in the same year investment cost £595 million, so that the electricity industry consumed more public money than it paid to the Exchequer. Obviously the only sensible question to ask about the charges is whether they should be varied by some small amount, one way or the other.

To begin with, there is a strong case for asking that nationalized industries in competition with each other—coal, gas and electricity, for example, or the two nationalized airlines—should have similar charges laid against them. One of the anomalies of the past few years has been that electricity has been more highly taxed than gas—a sign of how the gas industry seemed to be languishing when the charges were first specified in the early sixties. There is now the most urgent case for equalizing these two and also for making the coal industry pay a fair return on the capital it employs.

The charges should also be administered more flexibly. The sharp increase of electricity prices last week has come about because the industry has had to meet a number of unexpected costs in the course of a single year's operation. The demand has fallen behind the forward estimates on which the industry has based its calculations, principally because the Government's own economic plan has fallen into disarray. Some power station equipment has been slow in coming into service, which has also increased the industry's costs without adding to its productive capacity. In circumstances like these, it is essential that the nationalized industries should be able to spread hardship over more than the year in which it occurs. It would even make sense if the financial objectives set for the industries could be defined not by a single number but by some variable relationship with the parameters which affect the industry's operations. It would make sense, for example, to have a lower financial objective when the economy as a whole is lagging.

It is not at this stage clear whether the Prices and Incomes Board will have a chance to examine issues like these. According to the Prime Minister, the financial objectives are to remain the Government's prerogative, and a new version of the White Paper of 1961 is due to appear soon. But Mr Jones is a resourceful man, and it will be surprising if he does not find some way of pointing out that the present system is so cut and dried that it is an impediment to efficiency, not a help. But, even if the Prices and Incomes Board has for a time to examine the side issues, there are plenty of important questions to be asked. It would, for example, be good to know whether the electricity industry is entirely justified in its devotion to such a closely integrated transmission network that all the generating stations in the country can operate effectively as a single unit. A more general version of the same question is whether the public interest would be served if the industry deliberately offered a poorer service for a lower price. Certainly it is pertinent to ask why the industry should have accumulated an extra 17 per cent of generating capacity to guard against the chance that the coming winter will be exceptionally severe. In other words, by asking the right questions the Prices and Incomes Board can do a great deal not merely to rationalize the way in which the nationalized industries make use of scarce resources but also to ensure that they conduct themselves efficiently.

## POLYPEPTIDES OR AMINO-ACIDS

THE origin of biological macromolecules and life on Earth is, like the possibility of extra-terrestrial life, a subject for speculation and experiment. There is no likelihood of producing protein and nucleic acid self-replicating systems from simple inorganic molecules in the foreseeable future. This, quite rightly, does not deter everyone from seeing what can be obtained from simple mixtures of the gases that were probably present in the primeval atmosphere.

The primeval atmosphere was almost certainly a reducing environment containing hydrogen, methane, ammonia and hydrogen cyanide, so it seems reasonable to believe that proteins somehow arose from condensation products of these gases and water. When Miller (1955) in his pioneering experiments—repeated many times since—found that mixtures of ammonia, methane and water yield  $\alpha$  amino-acids when subjected to high energy radiation or electrical discharge, it was speculated that proteins arose in the primeval seas by polycondensation of  $\alpha$  amino-acids. Matthews and Moser, on page 1230 of this issue, question this idea. They suggest that polypeptides and proteins in fact arose directly from the condensation products of hydrogen cyanide, ammonia and other gases and not by the condensation of pre-existent  $\alpha$  amino-acids. They have shown that the products from mixtures of ammonia and hydrogen cyanide when dissolved in water yield polypeptides but no free amino-acids. On hydrolysis, this peptide material yields no fewer than fourteen  $\alpha$  amino-acids, assuming that the amide precursors of aspartic and glutamic acids were formed. As expected, because the gas mixture used contained no acetylene or hydrogen sulphide, aromatic and sulphur containing amino-acids were not formed.

Matthews and Moser propose that dimerization and subsequent polymerization of the hydrogen cyanide forms polyaminonitriles which then react with water to give the peptide material. They also believe that the free  $\alpha$  amino-acids found by other workers were in fact produced by the hydrolysis of peptides. If, as is likely, the primeval atmosphere contained acetylene and hydrogen sulphide, it is perfectly possible that polypeptides containing all twenty  $\alpha$  amino-acids were produced in this way and subsequently gave rise to today's proteins. It will be a long time before anybody can hope to know for certain whether polypeptides gave rise to  $\alpha$  amino-acids or whether things happened the other way about, but the idea is stimulating.

## NEWS GATHERING

LATER in the year, *Nature* will begin a new venture in gathering and presenting news about science to the public and the scientists. Under an agreement with the *Times* (of London), this journal will provide the *Times* with regular news of important developments in

science. This will take the form of a daily column written by the staff of *Nature*. At the same time, it will be possible for this journal to improve enormously on the news of developments within the profession of science which it at present offers to its readers. Not only will there be more people to do the work, but *Nature* will have access to the network of international communications at present used to provide the *Times* with a foreign news service.

Readers of both journals will benefit. *Nature* is particularly glad of an opportunity to help with the dissemination of news about science to the general public, for the excitement and significance of modern science are inadequately appreciated. It is important, however, that an arrangement like this should not compromise the independence of the two journals, which is why it has been agreed that *Nature* should be in sole charge of the contributions offered to the *Times* each day and that the service thus provided will supplement and not replace the coverage of science now provided by the *Times*. It goes without saying that contributors to *Nature* can be sure that their communications will in future, as in the past, be dealt with in confidence and objectively. If there is any interaction at all between the news service and the function of *Nature* as a vehicle for original communication, it will probably take the form of a further increase in the speed with which manuscripts are turned into print.

## NO LINGUA FRANCA

THE resignation last week of the Indian Foreign Minister, Mr M. C. Chagla, has again drawn attention to language problems in India and to the Indian Government's determination to implement immediately the decision to replace English by regional languages as the medium of teaching in Indian universities. It is easy enough to understand the Indian desire to remove what may seem to them to be vestiges of a colonial past, and there is plenty of evidence from elsewhere—Wales, for example—that language ranks high in national pride. But in India, with no universally spoken or accepted language, the change is impractical and unrealistic. It will inevitably lead to a lowering of the standards of education and to a further isolation of Indian universities which India can ill afford. Until Hindi, now spoken by only about 40 per cent of the population of India, has become a universal language, there are to be no fewer than fifteen accepted regional languages. Will India face the chaos of translating textbooks and journals into all of these? And will teachers be obliged to lecture in a language in which they lack proficiency? Many hoped that the English language might remain as the most useful legacy of imperial India, and it is ironic that the Indian Government has felt obliged to replace English by obscure regional languages. Will their decision help to ruin Indian unity as well as Indian universities?

## NEWS AND VIEWS

### Only Specialists Need Apply

THE first physical evidence of the drive to get British scientists back from the USA was unveiled this week in New York. Management Selection Ltd, which the Ministry of Technology recruited earlier this year to lead the drive, opened an information and recruitment centre in Park Lane. The centre is intended to provide help and information for engineers, scientists and managers who wish to return to Britain. Other centres are planned for San Francisco and Toronto.

Simply writing to MSL or the ministry is absolutely no guarantee that a job will be found. Since the ministry started its campaign, 400 British scientists in the USA have written asking for jobs in Britain, but very few have yet been placed. No doubt part of the reason for this is the difficulty of arranging interviews (which should be simplified now the MSL office is open), but the real reason is simply that industry in Britain has few vacancies to fill. Employers are not interested in flying to New York to recruit chemists if they can find men as good in Manchester. In some areas—data processing, electronics, management services, and some branches of engineering—there are genuine shortages, but in others employers are easily able to fill their needs within Britain. In the first quarter of 1967, only half as many jobs were advertised as in the first quarter of 1966. In these circumstances, British scientists wanting to come back to Britain are deluding themselves if they expect to be offered jobs on the spot.

MSL is tackling the problem by first finding out from British companies what their needs are. It may then be able to find among those who go to the office in New York candidates who have the necessary qualifications and experience. So far several hundred companies have been contacted, and asked what they will be needing over the next twelve months. Their needs are not always obvious; chemical companies may well be more interested in statisticians than in chemists, and engineering firms may be looking for systems analysts rather than engineers. At the moment, apart from the special fields, it looks as if there are more applicants than there are jobs. With the number of annual vacancies running at about 25,000, against 40,000 a year ago, this is not surprising. Like everything else, recruitment on a large scale from the USA is likely to have to wait for the end of the squeeze.

### How Many Social Scientists?

THE Social Science Research Council, set up in 1965 as a result of the Heyworth Report, is the body which makes the awards for postgraduate research in social science in British universities. Estimates as to the likely number of eligible graduates are given each year to the Treasury, which then decides the proportion which will be given awards. The money required for these grants (about £630 each) is, surprisingly, not the only criterion; the number of people tied up

in academic research rather than let loose on the world is also taken into account. At present, the Treasury and the SSRC have agreed that about 50 per cent of those eligible should be given awards. Although the proportion is rising every year it is taking longer than the SSRC would like to reach the 60 per cent recommended by the Heyworth Report.

Several universities have recently complained that large numbers of their eligible students (first or upper second class degrees) are being refused grants. In a letter to the *Times* on September 9, Professor Meek of the University of Leicester gave figures for his department—only four of the thirteen applicants received awards.

The SSRC allocates awards to each university on the basis of previous figures. A reserve of about 10 per cent is held back until the summer, and further grants are given on the results of final examinations. Here again there seems to be a shortage of awards. The London School of Economics, for example, filled its original quota and applied for fifty-seven further awards, only seventeen of which were granted. It has been found in the past, however, that some awards that were granted were not taken up, when universities have over-estimated their own appeal. The SSRC takes this into account when the allocations are made.

### Pugwash Meets

THE latest Pugwash conference has ended after a week of discussion at Ronneby, Sweden. Members of the conference met in a mood of self-examination: indeed, the organizers took the occasion of the tenth anniversary of the Pugwash movement to call a more comprehensive and larger conference (of about 200 members) than ever before, and to declare that one of its main purposes would be to review the aims and organization of the movement—to discuss its past achievement and to plan its future.

The history of the Pugwash conferences is remarkable. On an absurdly small budget—of about £4,000 a year—at its central office, under the dedicated and dynamic supervision of its originator and secretary-general, Professor J. Rotblat, the movement now has 22 national groups—some of them extremely active—and a continuing programme of international and national study groups and conferences.

What have been its achievements? At this conference one heard on all sides the conviction that they were considerable even though immeasurable and that the movement must continue. Although the conferences are private, reports of their proceedings are given to the press, to governments and to other interested institutions. Observers attend from many international organizations, such as the organs of the UN. But the main achievement is thought to be, in the now accepted jargon, its "fall-out" or "spin-off". Perhaps the most obvious fall-out is on the participants themselves, many of whom hold important advisory or even executive positions in their own countries. The unique feature of these conferences seems to be that the participants, bound by common commitment to science and scholarship—and by common habits of thought—find themselves discussing political issues with the familiar friendliness of ordinary scientific conferences. Regular Pugwashites will assert that they can detect changes in attitude between one

conference and the next in those with whom they have argued most keenly.

But some of the fall-out has been detectable and concrete. An example is the new Stockholm International Institute for Peace Research. This is an independent organization financed by the Swedish Government but, as the Prime Minister of Sweden told the conference at its opening session, it owes its existence to Pugwash.

The delegates came from nearly 40 countries, broadly representative as between East and West, and between advanced and developing nations. Indeed, one of the trends in recent years has been the increasing attendance from countries other than the UK, USA and USSR—though not at present including China. Representation from the USSR has always been high (it included Kapitza on this occasion); here Pugwash has probably been ahead even of conventional scientific conferences.

The work of the conference was done at many levels—in plenary sessions, in working groups, and in *ad hoc* committees. More than 70 invited or contributed papers were read, covering all aspects of science and world affairs, such as arms control and arms regulation; the resolution of current conflicts; the role of UNO international scientific programmes; assistance to developing nations; social responsibilities of scientists; the underlying reasons for conflict. Of course, no problems were solved; no doubt the final statements varied in real content in roughly inverse proportion to their political sensitivity. But there was a notable absence of complacency about the international situation or about the contribution of Pugwash. On the international scene an apparent détente between the “super-powers” comes at a time when “local” wars are perhaps more numerous than ever before. The conference was well aware of the instability of this situation, as the statement by the Continuing Committee shows.

The contribution of Pugwash in the future under its new President, Cockcroft, and chairman, Powell, will be by intensification of its own work. Conferences and study groups will be smaller but much more numerous, much more closely focused on particular problems, and much more professional in character. Perhaps even more important, the Pugwash movement must attract many more scientists—especially younger scientists—and must increase its budget. It is the only movement of its kind: the only independent international forum for scientists concerned about world affairs.

G. O. JONES

## Pugwash Statement

The safeguards system of the International Atomic Energy Agency got a nod of approval at the 17th Pugwash conference which has just taken place in Rönneby, Sweden (see preceding story). In the report of the continuing committee, which describes what went on, some details are given of the discussion on the problems of disarmament. While welcoming the tabling of the draft non-proliferation treaty, the conference regretted the omission of Article 3, which covers safeguards. Fears about inspection should be allayed, as far as possible, by minimizing the intrusiveness of the inspection, and ultimately it would be better if the nuclear states were subject to the same inspection as

the non-nuclear states. “The control system of the IAEA,” the statement says, “appears to be entirely adequate for the required inspection.” It goes on to say that because of the great importance of the non-proliferation treaty, countries should not impose conditions—such as other disarmament measures—on its acceptance. These are more likely to be successfully negotiated after the treaty is signed. One suggestion is that nuclear powers should undertake not to use nuclear weapons against states which have signed the treaty, which do not possess nuclear weapons and which are prepared to promise that there are no nuclear weapons on their territory.

The conference agreed that it is now possible to detect nuclear tests underground, so that there is no objection on technical grounds to extending the test ban treaty. The repeated outbreak of local wars not involving nuclear weapons alarmed the conference, and this statement warns of the dangers of the militarization of the oceans and of outer space, and of chemical and biological warfare. All nations were urged to adhere to the Geneva Protocol of 1925, and a formal treaty prohibiting the use and transport of chemical and biological weapons should be negotiated.

The conference agreed that all states should recognize the German Democratic Republic, and that both West and East Germany should be admitted to the United Nations without prejudicing the eventual reunification. The bombing of North Vietnam should be stopped immediately and unconditionally, peace negotiations should begin and a conference should be convened to establish a stable peace in South East Asia.

The conference returned to a discussion of a proposal previously made at Pugwash—the formation of an International Science Foundation within the UN to permit young scientists in developing countries to undertake research they would not otherwise be able to afford. The International Biological Programme seems to be going well in the developed countries but has so far failed in the underdeveloped countries for lack of funds. Too little is known, says the statement, about the production of essential foodstuffs in the tropics; the technical problems are linked with economic, religious and social ones. On a more optimistic note, the conference had hopes of the creation of what the statement calls “agro-industrial power complexes” in coastal deserts or in partly fertile areas. In essence, these would be large nuclear reactors producing electricity for desalination and fertilizer production.

## Task Force for COMSAT

THE restrictions governing communications in the United States have now become so archaic and contradictory that the corporations in command of satellites, computers and cables must hesitate before taking logical steps ahead, lest they run foul of the law. The fairly young Communications Satellite Corporation (COMSAT) is probably the most hamstrung of all. At the moment it is waiting to hear from the Federal Communications Commission whether it can spend some of its capital of \$200 million to provide an experimental domestic satellite service for the United States. Worse still, the corporation will have to hang on until 1969 to know what part it is ultimately to play in the International Telecommunications

Satellite Consortium (INTELSAT) of which it is now temporary manager. When COMSAT will know whether it can be permanent owner of an American domestic network is anybody's guess.

President Johnson has agreed at last that the Federal Communications Commission has neither the will nor the ability to deal with these questions, so that there is to be a task force under Mr Eugene Rostow, Under Secretary of State for Political Affairs, to analyse current regulations and the agencies which administer them. It would not be surprising if the group recommended elevating communications to the status of a full department. It may also suggest that anti-trust laws should be changed to allow COMSAT and the big communication companies to split. Hitherto COMSAT has felt at a disadvantage at the international bargaining table. There is an impression, which would not be confirmed by a study of British policy on satellites, that men from the British General Post Office can make clear what they want as prices, for example, while COMSAT's negotiators must keep in mind not only the national interest but that of the Federal Communications Commission, the small shareholders and the giant communications carriers—particularly the American Telephone and Telegraph Company, which owns half its stock.

The establishment of the task force may mean that the Federal Communications Commission will feel free to let COMSAT go ahead with a domestic satellite system on an experimental basis. The commission is well known to hate making up its mind; now the difficult decision about permanent ownership can be postponed until the task force reports. COMSAT has kept its critics in mind in drawing up its plan. It has offered—quite needlessly—to relay telephone calls by sending one voice by satellite and the answering party by ground line in the hope that this might quieten the fears of AT & T, which is worried about its investment in ground lines. COMSAT also hopes to crush the Ford Foundation's proposal to have a non-profit corporation set up to do the same thing by offering free channels for educational television.

One of the principal motives in the appointment of a communications task force was undoubtedly the imminent expiration, in 1969, of the interim agreement on INTELSAT. A permanent agreement on the ownership and operation of a global commercial satellite network must then be thrashed out. President Johnson has pledged the United States to work for a continuation of the consortium, in which the representatives of 58 countries are now members. He has asked the Soviet Union to think again about joining (instead of forming a rival network of its own). And, as bait, he suggested that COMSAT might be allowed to drop down from its present 54 per cent share of the votes in the consortium. 40 per cent is being mentioned as a possible ceiling, but it is unlikely that this will satisfy foreign critics of COMSAT's dominance.

## Japanese Space

THIS autumn may see the launching of the first Japanese preliminary satellite, which would be a small one. The launch vehicle Lambda 4S will have its fourth and fifth firings in the next two months, in the hope of overcoming difficulties which led to the failure of the first three launches. Since the failures, a violent

press attack has been directed at the Institute of Space and Aeronautical Science at Tokyo University, whose Professor of Engineering, Professor Itokawa, has been the inspiration behind the Japanese space effort. When a government inquiry into the affairs of the institute was begun in the spring, Professor Itokawa resigned, nominally to make way for a younger man, and, despite the support of his colleagues, has refused to be reinstated.

If all goes well, the first launching of a full scale satellite by the larger Mu rocket should take place in March 1968. The Science and Technology Agency recently admitted, however, that the programme has fallen behind schedule. One of the reasons for this seems to be the opposition of local fishermen, both to the erection of shore buildings and to the proposed orbital launchings at Uchinoura near Kagoshima. Already local opposition has caused the cancellation of a programme in which ten meteorological rockets were to have been launched. As a first step in resolving the muddle, greater integration of Japan's main space agencies was begun this summer. As a result, the Space Development Long Range Planning Office was set up, with representatives from the Science and Technology Agency, the Meteorological Agency, and the Ministries of Transport, Posts, Construction and Trade. The Institute of Space and Aeronautical Science at Tokyo is not represented, however, as "this might violate the autonomy of the university".

## Canals for Pleasure

THE Ministry of Transport is to spend £340,000 to improve and maintain 1,400 miles of canals so that they can be used for fishing and boating. The canals, most of them in the Midlands, are of no commercial value and their upkeep would in any case cost £600,000, so that the comparatively small expense of keeping them open for pleasure craft is fully justified. A mere twenty-eight miles of the canal system is to close, either because the canal passes through unattractive countryside, as in the case of the final section of the Leeds-Liverpool Canal, or because there are too many locks over a section serving too little traffic, as with part of the Sheffield-South Yorkshire Canal. By encouraging the development of facilities for pleasure craft, there is hope that the Canal system will come to cost the taxpayer less. There is even a possibility that some of the 600 miles of unnavigable waterways owned by the British Waterways Board may be reopened to traffic. A new Inland Waterways Advisory Council is to be established to deal with suggestions from those interested in the development of the canals, though the Waterways Board itself has co-operated admirably in the past with voluntary organizations, as, for instance, in the recent development of the Stafford and Worcester Canal.

## Profitable Airports

THE British Airports Authority was set up eighteen months ago to run the principal international airports in Britain on a profitable commercial basis. The first annual report of the authority shows that, within these terms of reference, the first year was successful. Finance is not the only consideration, however, as the authority also aims to provide good services, facilities

and public relations for both travellers and local residents.

Heathrow, Gatwick, Stansted and Prestwick—the four international airports formerly owned by the Ministry of Aviation—were handed over to the authority in April 1966. They represent a small proportion of the eighteen airports in Britain with scheduled services, but between them they handle 60 per cent of the total passenger traffic. Gatwick, struggling with seasonal traffic problems, could not balance its winter deficits by its summer profits. Stansted, on the brink of development, also failed to produce an operating surplus. Prestwick succeeded, however, and Heathrow, handling more international passengers than any other airport in the world, made enough for the authority to record a net profit before tax of £2.7 million.

Prestwick, owned by the authority, is as yet less busy than Abbotsinch, the other airport in Glasgow which is owned by the city. The two are being developed side by side, however; Prestwick, with tartan trimmings and welcoming early morning music, is to concentrate on long distance intercontinental flights, leaving short hauls and domestic routes to Abbotsinch.

Although the authority seems to have started well, there is as yet little talk of its taking on any other airports. The Board of Trade runs several airports and the rest, apart from a few private ones, are municipally owned. Not all of them are making a profit and, unless there is a chance of financial viability, it is unlikely that the authority will be able to take them on. Talks are at present going on, however, between the authority and the Board of Trade about the future of Edinburgh airport which the city council has declined to look after. The authority is building up a specialized staff of airport developers, and is prepared to act on a consultancy basis if its advice is sought.

## Death of an Elephant

THE post-mortem on Diksie, the London Zoo's twenty-seven year old African elephant which died last week after falling into the dry moat around her enclosure, has revealed that she had serious injuries from which she could not have recovered. The main nerve of the left front leg was severed—a result of the way in which she fell and landed off balance. Her right tusk was broken, and she was concussed—she hit her head on the front wall of the moat. With injuries such as these nothing could have been done to save the four ton elephant. The zoo's lifting equipment could have lifted her into a standing position had she not been injured. With her damaged leg it would have been necessary to destroy the elephant even if the rescue operation had been successful.

Elephants have fallen before during the past twenty years. In her previous enclosure Diksie fell into the moat, which was deeper than the present one, and was removed safely. An Indian elephant has also fallen into the same moat in which Diksie died, but was unhurt and was brought out with little difficulty. Last week's was the first fatality, the result of an awkward fall.

The zoo says that it has no reason to doubt the efficiency of the moat. It is, however, considering banning all feeding of elephants by the public, because the animals would not then be encouraged to stand at

the edge of the moat and stretch out their trunks to catch items of food. It was this that was partly responsible for Diksie's fall. A ban on feeding, with warning notices and constant supervision by staff, works effectively in continental zoos, and its introduction in London would not be untimely.

## Software for Teaching

EDUCATIONAL technology sounds like a grand name for teaching machines, but in fact it includes a great deal more than hardware. Closed circuit television and language laboratories cannot work by themselves, and the provision of the right programmes for such machines is a task which is receiving increasing attention. On a more fundamental level, research is now being done to find the best use for each type of machine and the most effective means of using the machines in teaching actual subjects. The creation of the National Council on Educational Technology is a sign of the times.

The latest group to take up this type of work in Britain is the newly established Institute for Educational Technology at the University of Surrey. Professor L. R. B. Elton, head of the physics department, will be taking charge of the institute, which he believes to be the first of its kind in Britain concentrating on teaching aids in universities. The Massachusetts Institute of Technology has such a department, but most of the work on audio-visual aids in Britain, at Leeds and Sussex, for example, has been for the secondary school level.

The new institute at Surrey will be working in close touch with the several departments in the university, and Professor Elton hopes that this unusual relationship, which will link the educational research directly with the teaching methods in use in each subject, will prove fruitful. The teaching of first year students is one of the first important areas for investigation, and this will be studied in connexion with sixth form teaching, as the two are so closely related.

In the present buildings in Battersea there is little room for the institute to take on students, but when the university moves to Guildford in 1968 it is hoped that students will be able to take higher degrees in this expanding field. Students who can take postgraduate courses in educational technology will be well equipped to raise standards when they begin to teach. Studies of this nature may also encourage more science students to apply themselves to teaching. The institute hopes also to encourage school teachers in the area to join in this work so that the results of research can be put into practice.

A grant of £1,350 has been awarded to the Institute by the Social Science Research Council for a particular project concerned with the transition between school and university. Philips Industries has offered support, particularly in the form of machinery, and other finances are being provided through the usual university channels.

## Brakes without Skids

A RECENT study by Mr J. K. Meades of the Road Research Laboratory shows that different tread patterns have only a small effect on braking efficiency on wet roads. Mr Meades tested five different cross ply

tyres and five radial tyres on four different wet road surfaces. Of the two groups, radials were slightly the better, but within each group the differences attributable to tyre tread and material are less than the scatter of the experiment. Only one type, an Italian tyre not recommended for British roads, was significantly worse than the rest. The generally better performance of the radials, Mr Meades concludes, is consistent with the view that they are better at removing water from the contact region; at 80 m.p.h. on polished concrete the peak braking coefficient for radials was 0.6, while that for cross ply tyres was 0.5.

The experiments also showed that when the wheels lock, braking coefficients are frequently reduced by a factor of two or three, and occasionally by as much as eight. Drivers are therefore in danger of over-estimating the braking power available to them. Automatic braking devices which prevent the wheels from locking offer a chance of making the best use of the friction available. Perhaps more important, though, is the need to retain directional control, which is almost completely lost when the wheels lock. Skidding, the laboratory estimates, is involved in about 70,000 accidents each year; 33 per cent of all accidents in wet conditions involve skidding.

Several systems of automatic brake control have been announced. The Dunlop Maxaret system uses a rubber tyred wheel driven by the road wheel which it controls. Within the driven wheel is a flywheel kept in driving contact by a spring; normally the flywheel rotates at the same speed as the driven wheel, but when brakes are applied and the driven wheel decelerates, the flywheel continues to rotate against the resistance of the spring and operates valves which release the brakes. The driven wheel then accelerates again, catches up with the flywheel, and the brakes are re-applied. Experiments almost ten years ago at the RRL by R. D. Lister and R. D. Kemp showed that units of this type can reduce braking distances and give much better control during braking.

Lockheed have also produced a system of control, called the Lockheed Antilock. This operates on the rear wheels only, and uses an inertial system driven from the propeller shaft to prevent the rear wheels locking. The system has demonstrated that braking distances can be reduced and directional stability maintained. Another system, the Kerr Antilocking device, makes use of the forces produced in the suspension of the vehicle to release the brakes when the wheels begin to slip. Yet another, the Autostable braking system, makes use of torque reactions on the front brake shoes to regulate the pressure to the rear shoes.

Although several of these systems have been convincingly demonstrated, their use is still very restricted. The Dunlop Maxaret system, used on aircraft, has been fitted to some commercial articulated vehicles, at a cost of £150 per axle converted. Cost may well be more significant than technical factors, and it is probable that antilock devices will not achieve widespread acceptance until their use is compelled by legislation.

## Keeping Armies in Touch

BRITAIN has joined the United States, Australia and Canada in a collaborative project to develop a tactical trunk communications system for their armed forces.

The United States, Canada and Australia ratified an agreement to proceed with the project, called Mallard, in April of this year, but Britain deferred a decision because the problem of the sharing of costs and work had not been resolved. The project will cost about £45 million over 8 years in research and development, of which the United States will pay about 60 per cent, Britain about 30 per cent and Australia and Canada about 10 per cent. When the scheme goes into operation towards the end of the seventies, it is expected to cost between £200 million and £350 million. Each country will have the right to place contracts for up to one-half of its production requirements where it wishes, but the balance will be open to competitive tendering.

The Mallard system is a development of the British "Hobart Plan" for a digital tactical communications system. The United States authorities considered that this sort of system could not be developed until the early eighties instead of the middle seventies, and so had been developing a less sophisticated analogue system. The Mallard system will provide secure, fully automatic, switched communications in the battlefield area from army headquarters down to battalion level and will link up with the "Clansman" system down to forward battle positions. It will also link up with other strategic communications systems including "Skynet", the satellite system. It will have facilities for transmitting and receiving speech, telegraph, data and facsimile, and will replace the "Bruin" system, a microwave trunk telephone communications system due to come into service next year.

In the initial development phase of the programme, the competitive system design studies will be carried out by United States and British electronics companies. A consortium of GEC, Marconi, Plessey and STC, co-ordinated by the Signal Research and Development Establishment, has been formed to do the design studies in Britain. Other companies will be called into the consortium as required, and when the system is developed it is hoped that other countries in NATO will buy it.

## EMBO Fellows

SIXTEEN long-term fellowship awards for 1967/68 have been announced by the European Molecular Biology Organization. These awards, tenable for a year, allow research workers in molecular biology to attend centres to continue their research. Although the organization is European, it does award fellowships to non-Europeans who wish to work in Europe and to Europeans who wish to work outside Europe.

Among the fellowships awarded, Dr Ch. Phelps, of Bristol, has received one to work on conformational changes and enzyme kinetics at the Istituto di Chimica Biologica, Centro di Biologia Molecolare, Rome; Dr L. Cordone, of Palermo, has received one to work on messenger-ribosome relations at the Laboratory of Genetics of Brussels University; and Dr J. P. Richardson, of Cambridge, Massachusetts, has received one to work on the structure of RNA polymerase at the Institut de Biologie Moleculaire, Geneva University. EMBO has also renewed the fellowship awards of Dr C. Vesco, at the Department of Biology, MIT; Dr J. Witz, at the Laboratory of Molecular Biology, Cambridge University; Dr E. Pojnar, at the Department

of Botany, Nottingham University; and Miss S. A. Bonanou, at the National Institute for Medical Research, London.

During the year EMBO has sponsored five summer courses in molecular biology. These covered separation methods, immunology, steroid biochemistry, ribonucleic acid and electron microscopy.

## Depth Perception

from a Neurophysiology Correspondent

FOR several years Julesz has studied binocular interactions in human vision using pairs of patterns which give a depth percept, when fused binocularly, exactly as in a normal stereoscope, but in which no structure is apparent monocularly. The stimuli are patterns of equal numbers of black or white square picture elements generated by computer and arranged at random in square arrays 100 elements square. The two members of a pair are identical except for the central array ( $40 \times 40$  squares) of which one is shifted horizontally by an integral number of elements with respect to the centre of the other. When the two patterns are fused binocularly in a stereoscope, this disparity leads to the percept of a central square. At first, subjective development of the square may be slow; when it is seen it appears in a plane in front of or behind the surround, depending on the direction of the disparity. This demonstrates that depth perception and the cross-correlation necessary to establish the disparity of two images can be an entirely central process, independent of monocularly visible structure and complex pattern recognition and of eye movements and vergence, but a function of time. The experiment therefore provides an ingenious technique for investigating purely central mechanisms, as any structure apparent in the fused image is a central percept (*Science*, **145**, 356-362; 1964).

In recent publications, Julesz and his colleagues describe extensions to their first experiment. When there is a monocularly apparent structure in one of a pair of random dot patterns which also contains a shape only visible when binocularly fused, the binocular "central" percept entirely predominates. This is true for patterns containing strong bilateral or higher order symmetries seen monocularly, as well as for patterns containing familiar words (Julesz, *Bell Syst. Tech. Journal*, **46**, 1203; 1967). Thus, when binocular interactions occur, they dominate the perception of monocularly perceived symmetries.

Julesz and Spivack (*Science*, **157**, 563; 1967) describe experiments with patterns made up of thin straight line segments. These, too, are drawn by computer, and consist of grids of thin vertical or horizontal lines. The lines are black, one dot thick and ten apart. For a vertical grid each line segment is in the vertical meridian of a 10 dot square element, or is displaced horizontally by two dots. The two types of segment are arranged at random, so that the monocular percept is of a grid of narrow lines with random breaks at intervals of ten dots, or an integral multiple of ten. As before, the two images of a pair are identical except for the central array of  $40 \times 40$  picture elements which in one is shifted horizontally by a single (10-dot) element. Even when the targets are viewed at a distance at which the breaks subtend only 16 seconds

of arc at the retina, perception of a square in depth occurs on fusion.

This is below the limits of normal visual acuity, but within those for vernier acuity. The authors suggest that the process used in vernier acuity is used in the cross-correlation on which global stereopsis depends. They also demonstrate an anisotropy for global stereopsis with these targets: stereopsis with horizontal line grids was stronger than with vertical grids, withstanding a disparity of the central square up to three times larger. This suggests that global stereopsis does not depend on local fusion, which is roughly isotropic (disparities in any direction between two retinal images less than about 6 seconds of arc are fused easily), but on local stereopsis, which is anisotropic, occurring for disparities only in the horizontal plane shared by the two eyes. Another interesting feature of these results is that even though horizontal displacement of the central square in one image will produce, by chance, 50 per cent of lines with zero disparity and 25 per cent each of lines with two dot disparity in either direction, a locally acceptable depth percept in terms of these disparities is rejected in favour of a more global percept, which must require more central processing for its detection.

Fender and Julesz (*J. Opt. Soc. Amer.*, **57**, 819-830; 1967) have further investigated the limits of fusion, using pairs of images stabilized on the retinae. With their stabilization technique, the two images of a stereoscopic pair can be moved apart without the possibility of the movement being counteracted by vergence movements of the eyes. Under these conditions, once fusion is established within Panum's fusional area (that is, with a binocular disparity of less than 6 seconds of arc for foveal vision), the two targets can be separated—literally pulled apart on the retinae—without loss of fusion for a distance of up to  $2^\circ$  provided that the pulling is not too fast and that the stimuli are never occluded. If the pulling velocity is above a certain limit, or the stimulus is occluded, fusion breaks down and can only be re-established within Panum's fusional area. With random dot patterns fusion is maintained for a greater distance of movement than with a pair of single lines. The authors interpret their results as follows: a labelling process, operating within Panum's fusional area, establishes correlations between corresponding points of the images on the two retinae. This process takes time, but once labels are established they can be preserved by a "cortical registration process", allowing the images to be pulled apart, within limits, without loss of fusion. Finally, there is a process preserving labelling against saccadic eye-movements, which do not destroy fusion in normal vision.

Julesz' work emphasizes the relation between the spatial and temporal aspects of fusion, while showing that in some ways it is a simpler process than had been thought. In normal vision, eye movements and vergence as well as object movements might all upset fusion without the hysteresis phenomena characteristic of binocular interaction.

## Cold Star

from an Astronomy Correspondent

RECENT interest in quasars has somewhat obscured the extraordinary development that has been occurring in

infra-red astronomy in the past few years. The latest surprise, announced in the most recent number of *Astrophysical Journal Letters* (149, L1; 1967), is the discovery by D. E. Kleinmann and F. J. Low of a new source of infra-red radiation in the Orion nebula. This has been detected at a wavelength of 22 microns and covers an area of sky 30 secs of arc in diameter. Using the observed flux and angular diameter, the brightness temperature of the source is only 70° K (about the temperature at which nitrogen liquefies). But at all wavelengths, it probably emits at least one hundred thousand times as much radiation as the Sun. Looking at 5 microns in another "window" where the Earth's atmosphere is sufficiently transparent to observe the sky, Kleinmann and Low failed to detect the source, thus confirming its low temperature. Nearby, however, is another source of infra-red radiation known as Decklin's star after its discoverer. The latter, with a higher temperature (about 600° K), emits powerfully at 5 microns but is not detected at 22 microns by Kleinmann and Low. The relation, if any, between these sources is an exciting puzzle for the theorists.

If the 22 micron source were in front of the Orion nebula, it would be seen in optical wavelengths as a black cloud superimposed on the bright background. Since no such black region exists, it is behind or inside the nebula. So far, two theories have been advanced to account for this peculiar object. One, championed by A. G. W. Cameron and W. K. Hartmann, is that the radiation comes from the gravitational contraction of a proto-cluster of stars which are still forming from dust and gas. On this view, it is far behind the Orion nebula, and the fact that it is in the same direction as the nebula, another important star formation region, is a coincidence. Another point of view put forward by M. Harwit and K. Davidson is that it is a single very luminous star in the midst of the Orion nebula which is cocooned in the dust cloud from which it was formed. The "cocoon-star" would be surrounded by a sphere of hydrogen ionized by the star's radiation and contained within the cocoon. This gives hope of distinguishing between the two theories by radio observations of the bremsstrahlung emission from the ionized hydrogen region.

## Transport of Secretory Protein

from our Cell Biology Correspondent

OVER the past decade the beautiful work of Palade and his collaborators has revealed the essential features of the secretory cycle in pancreatic exocrine cells. The cycle can be divided into four steps: (1) the synthesis of enzymes and zymogens on ribosomes attached to the endoplasmic reticulum; (2) transfer of the protein to the cisternae of this reticulum; (3) intracellular transport of the protein to the Golgi complex where it is packed in zymogen granules; and (4) discharge of the zymogen granules into the glandular lumina. The third of these steps is least understood. Caro and Palade (1964) showed with autoradiography that, within 10 min of synthesis, the protein reaches the condensing vacuoles of the Golgi complex where it is concentrated, but because of the low resolution of autoradiography they were unable to answer the vital

question: does the protein migrate to the Golgi complex through the cytoplasmic matrix or is it transported there in membrane bound vesicles? Data obtained in the early days of cell fractionation suggested the former route, but, as Jamieson and Palade (*J. Cell Biol.*, **34**, 577 and 597; 1967) have now shown, the secretory protein is in fact transported from the cisternae of the endoplasmic reticulum to the Golgi complex in vesicles.

To establish this they overcame the difficulties which make it impossible to give a short pulse of labelled amino-acid to the pancreas *in vivo*. Instead, they incubated slices of guinea-pig pancreas in a medium containing <sup>14</sup>C leucine for 3 min and then chased the label by incubating in cold medium. The tissue slices were homogenized either immediately after labelling or at intervals during the chase and fractionated by gradient centrifugation. In this way they determined the kinetics of labelling of the rough microsomes (derived from the ER), the smooth microsomes (derived from the periphery of the Golgi complex), and the condensing vacuoles and zymogen granules.

Immediately after giving the pulse the labelled protein is in the rough microsomes, but during a 7 min chase it is transferred to the smooth microsomes and it then accumulates in the zymogen granules, reaching a maximum concentration after 37 to 57 min. Furthermore, the labelled protein is in the lumen of the microsomes not associated with the bounding membrane and throughout the whole experiment the specific radioactivity of the post microsomal proteins—proteins of the cytoplasmic matrix *in vivo*—remains constant. Clearly, newly synthesized secretory protein is never released into the cell sap but is always kept within membrane bound spaces as it is moved about the cell. On this basis Jamieson and Palade propose a scheme for the intracellular transport of secretory protein that is applicable not only to exocrine pancreas cells but all gland cells specialized for the synthesis, concentration, temporary storage and eventual export of protein.

They envisage that as secretory protein is synthesized it passes immediately across the membrane of the endoplasmic reticulum into the lumina of the cisternae—Sabatini, Tashiro and Palade (*J. Mol. Biol.*, **19**, 503; 1966) suggested how this might occur. Once sequestered within the cisternae the protein can be moved to the transitional zone where the endoplasmic reticulum and Golgi complex meet. Small vesicles then shuttle backward and forward, transporting accumulated protein from the reticulum to the condensing vacuoles of the Golgi complex—there is morphological evidence which suggests this—and in the condensing vacuoles it is concentrated, perhaps by ion pumps; the condensing vacuoles thus become secretory granules. Thus from the very initiation of its synthesis the secretory protein is segregated and directly channelled into a secretory granule.

## Denatured States of DNA

from our Molecular Biology Correspondent

A FRACTIONATION technique of great potential, which has so far received surprisingly little attention, is partition between aqueous polymer two-phase systems.

This method is a product of the Swedish school, and has been developed mainly by Albertsson. Two water-soluble polymers are used, which in appropriate proportions generate two phases, between which water-soluble molecules, such as proteins and nucleic acids, can be distributed. Albertsson showed, for example, that in an aqueous dextran-polyethylene glycol system single and double-stranded DNA will tend to concentrate in opposite phases. A careful exploration by Alberts (*Biochemistry*, **6**, 2527; 1967) of the effect of concentration and proportion of the two polymer components and of salt concentration on the partition coefficients of native and denatured DNA has now produced the spectacular result that these species can be completely separated by a single partition. The conditions in terms of polymer and salt concentration are critical, but, once established, the fractionation involves only thorough mixing and layering of the phases by low-speed centrifugation. The native DNA enters the upper (polyethylene glycol) phase, and is isolated by salting out the polymer; the denatured DNA can be recovered from the lower phase by another extraction under different conditions.

Among several applications described by Alberts is the isolation of a small fraction of "reversible" DNA, present in denatured DNA: it contains cross-links which enable it to return to the fully base-paired state when the denaturing conditions are reversed. It therefore quantitatively enters the upper phase of the partition system. Many uses will surely be found for this interesting technique, such as the separation of single and double-stranded viral nucleic acids, isolation of hybrids, renaturable fractions from animal cells, and so on.

A study of the course of thermal denaturation in  $\lambda$  DNA by electron microscopy is described in an article by Inman (*J. Mol. Biol.*, **28**, 103; 1967). It follows an earlier report that when  $\lambda$  DNA was partially denatured by heating, melted regions ("puddles" in the electron micrographs) appeared preferentially in certain parts of the molecule. The native DNA has a narrow length distribution, clustered around  $18.5\mu$ . By measuring the distances along the chain of the melted segments in a population of molecules which have been exposed to a denaturing temperature for a given time, Inman compiles "denaturation maps". When a plot is constructed of the number of melted regions summed over all the molecules in the field as a function of distance from the end, it is seen that the early stages of denaturation are highly localized. Thus, at the lowest observable degrees of denaturation, a single melted zone is observed, which is followed by two more as the temperature of denaturation is raised. The first zone then sub-divides, apparently into four. The three major zones of melting are then centred  $8.9$ – $11.3\mu$ ,  $13.7\mu$  and  $17.9\mu$  from the end of the molecule, and are thus all situated in one half (the right half) of the chain. As the degree of denaturation is increased, zones appear in the left half of the molecule, though these are less sharply defined than the others. Thereafter the denaturation spreads and the pattern vanishes. The extent of the denaturation is determined both by the temperature of heating and the time it is allowed to remain there.

One of the conclusions is that all  $\lambda$  DNA molecules are similar in sequence. It must be supposed that the

labile regions are much richer in A-T than the remainder. In 1962 Felsenfeld and Sandeen noted, however, that T4 DNA showed only a very small spread of base composition of regions melting at different temperatures—much smaller than the highly heterogeneous calf thymus DNA. The present results invite a similar spectrophotometric analysis. They appear in any event to reflect much more non-co-operative melting than has previously been expected.

## The Physics of Quasars

from a Correspondent

FOLLOWING closely on the General Assembly of the International Astronomical Union at Prague, the Conference on the Physics of Quasars at Manchester allowed a more detailed look at recent observations and theory than could be afforded in the unwieldy milieu of the big assembly. The conference was arranged by the Institute of Physics and the Physical Society, with the Royal Astronomical Society, primarily to bring more physicists into contact with astronomers. The astronomers already immersed in the problems of quasars are not, however, averse to arguing between themselves, since neither the optical nor the radio observations provide an unequivocal picture of the facts which physical theory must explain.

The optical evidence, summarized by Professor Maarten Schmidt, has not changed dramatically in recent months (see F. G. Smith, *Nature*, **213**, 967; 1967). A quasar is still defined as a radio source of stellar appearance, intense in blue and ultra-violet light, often optically variable, and with emission lines shifted very far to the red. There seem to be at least  $10^5$  of these detectable in the whole sky, if we may include some which are not intense radio emitters. Some oddities remain about their distribution over the sky, but most observers do not place much emphasis on this, and consider instead their distribution with distance. Quasars are evidently not uniformly spaced through the observable universe, but increase in numbers at increasing distances, as indeed has been indicated for some time by the counts of radio sources. Further analysis of the relation between red-shift and optical and radio magnitudes was described by Longair and Scheuer and by Daintree and Horton (*Nature*, **215**, 917; 1967), but none of these analyses can yet say anything about the controversial question of the actual distances, or choose between cosmological models if the red-shifts are interpreted according to Hubble. They cannot even indicate whether part of the red-shift is caused by a strong gravitational field, which is the contention of those who support the smaller distance scales.

Variability, both optical and radio, has been detected in about a dozen quasars. Cannon and Penston are continuing a particularly useful series of optical observations at Herstmonceux, and regular radio observations are now being made at many observatories. It seems inescapable that the rapid fluctuations indicate that the main light source of these quasars is very small, possibly only about the size of the solar system. The optical emission lines must come from a larger region, a few parsecs across, resembling the planetary nebulae. Radio waves could not penetrate a uniform plasma of this type, so they must escape

from the centre through irregularities, or else they must be generated outside. The total emission represents an enormous power, whether the quasars are placed at some tens or some thousands of megaparsecs; evidently the central bright object contains a mass comparable with that of an entire galaxy, much of which is being converted to radiated energy via high energy electrons and a magnetic field. Theoretical arguments by Burbidge, Scheuer and Rees could only refer to this as "the horrid object X", although they did show that the observed properties of the radiation could be accounted for by a combination of synchrotron and inverse Compton radiation.

Although a rough physical picture of the radiation processes could be presented, no agreement was reached on the burning question of distance. Hoyle pointed out that such massive objects, with such small size, would undoubtedly have very large gravitational fields in the emitting regions. It might be quite wrong to apply our familiar physics, or to interpret red-shifts simply as recession velocities under such unusual circumstances.

In spite of the fog surrounding all attempts at interpretation, everyone agreed that the current pitch of excitement in the quasar story could only be matched by the era forty years ago, when Hubble discovered the law of recession of the nebulae. Two kinds of information are expected to emerge. Cosmologically, the quasars are important whatever their distance may be, since either they provide a searching test of cosmological models or they represent a local example of a cataclysmic event on a scale far greater than any previously envisaged in the evolution of galaxies. Physically, the release of energy on such a scale, possibly amounting to  $10^{62}$  ergs, equivalent to the conversion into energy of the whole mass of a small galaxy, and the existence of very strong gravitational

fields, represent conditions unthinkable in any terrestrial laboratory.

Experimental work also divides into two lines. The detailed physics of quasars can only be elucidated by further work on their characteristics, such as their variability, spectral lines, red-shift and polarization. Their place among other celestial objects, and particularly the radio galaxies, needs sky surveys and detailed maps of as many objects as possible. Some observers, particularly Ryle and Sandage, regard the quasars and radio galaxies as one continuous evolutionary series, while others, notably Hoyle, do not believe this "continuity" exists. Family resemblances are emerging, nevertheless: some optically normal quasars have the radio appearance of a radio galaxy, while some optically ordinary galaxies have a radio object like a quasar within them. Again, Oke has reported a radio galaxy, 3C 371, which has an optically variable nucleus; by contrast the radio measurements of diameters show that at least one-third of radio galaxies contain small bright radio condensations, again like quasars. No one can yet suggest an evolutionary sequence, or guess at the proportion of galaxies which are connected with quasars at some stage of their existence, but quasars are evidently not just an uncommon freak.

Perhaps the best conferences cannot be expected to provide answers, but only to highlight some particularly interesting but difficult problems. If so, this was a very good conference. It was certainly an enjoyable and comfortable conference, with the new Schuster Physics Laboratory at our disposal, and with accommodation in the Owens Park student residence. The final meeting was held at Jodrell Bank, where a tour of experiments in progress displayed results on an occultation of a quasar and some long baseline interferometry obtained while the conference was in progress.

## Retrospect

by

SIR JOHN COCKCROFT  
Churchill College,  
Cambridge

Sir John Cockcroft, until recently a part-time member of the United Kingdom Atomic Energy Authority, reviews the authority's past achievements and its future.

THE late 1940s and early 1950s was the Golden Age of atomic energy development in Britain. We had by then equipped ourselves with the essential technological tools at Harwell—the research reactors and nuclear accelerators; the chemical, metallurgical and physical laboratories. Technological information had been developed to enable the Risley Industrial Group to build the Windscale plutonium production reactors and the chemical separation plant.

So, from 1948, we were able to turn our attention to the fascinating challenge of producing nuclear power. We had to increase the operating temperature of uranium fuel elements to the point when steam could be produced at temperatures and pressures sufficient to produce a reasonable thermal efficiency for the generation of electricity. A choice had to be made between the competing varieties of reactor. The fast breeder reactor was an early favourite, but it was seen that the quantities of plutonium or uranium-235 required for commercial power stations

would not be available in the 1950s. From the three possible types of thermal reactors we chose graphite moderated, natural uranium fuelled reactors because the alternatives required enriched uranium and heavy water which were unlikely to be available in Britain in sufficient quantities in the 1950s.

There were two main classes of problems. The first was to design a nuclear power station which would have a reasonable capital cost per kilowatt. Our rough estimates, made between 1948 and 1953, fluctuated by a factor of 2 but encouraged us to believe that nuclear power could be generated for about 1d. per unit—with the 4 per cent interest rates then prevailing. These cost estimates became firmer as the Risley Group took over the design of "Project PIPPA" and developed it into the Calder Hall nuclear power station. The second group of problems were technological. We had to prove that the graphite and uranium fuel would not be seriously affected by radiation damage; that the  $\text{CO}_2$  heat transfer gas would not

react too violently with the graphite in the presence of radiation; that the heat transfer problems could be solved; that the nuclear parameters of the reactor were correct. All these points were checked by experiments and this took about five years—a quite reasonable period for such development.

The Risley engineers showed that it was possible to design large scale nuclear plants within the estimates and within the time schedule. This was achieved by rigorous cost control and by an efficient progressing system which overcame all the bottlenecks. Harwell was successful in foreseeing most of the technological problems which had to be studied and solved. A good pattern of collaboration between designers and technologists was established and collaboration with industry and the Electricity Generating Board was very helpful.

When the generating boards embarked on the first stage of their nuclear power programme the role of the authority changed, so far as "magnox" stations were concerned, to that of an adviser on design, but it still contributed to the technology through the development of fuel elements using the facilities of the materials testing reactors and Calder Hall. The authority also retained responsibility for the development and construction of prototype reactors and for the trading activities of fuel element production and processing, and production of radioactive isotopes. This trading activity, which now has an annual turnover of the order of £30 million and makes a reasonable commercial profit, will be appreciably assisted if Britain joins the European Economic Community.

There has been a large scale, fruitful interaction with industry in addition to nuclear power station construction. Harwell has placed about 1,400 development contracts with industry since 1946 (*Nature*, 214, 343; 1967). Many of these were for the development of instruments which have had a wide application in industry and in universities—scalars, thickness gauges, polarographs, for example. The research reactors DIDO and PLUTO have been replicated by industry at Dounreay and in Australia, Denmark and Germany, and the electron linear accelerators pioneered by the Atomic Energy Research Establishment have been commercially developed for radiotherapy, radiation sources and university research. The production of 100,000 c. cobalt-60 sources in the Calder Hall reactors enabled Wantage to establish a new radiation application industry for sterilization of medical supplies and British companies have built or secured orders for four plants in Britain, one in Australia and five in Europe.

It was natural for Harwell to establish close relations with the universities. Nuclear and solid state physicists were encouraged to use the Harwell accelerators and research reactors. More than 50 graduate students and many university staff worked at a particular time in this way, anticipating the Sutherland report by more than a decade, and neutron crystallography developed out of this association. The early Harwell interest in helium-3 separation led to Dr London's helium-3 cycle for producing temperatures down to 0.01° K. But undoubtedly the greatest contribution of Harwell and the Radiochemical Centre to university research has been the production and speedy supply of radioactive isotopes and their incorporation into organic compounds for biological research throughout the world.

The associated Medical Research Council Radio-biological Laboratory at Harwell has a similar record of achievement. One of its most important discoveries was the method of making visible human chromosomes. Almost at once this showed that chromosome abnormalities led to specific human defects—the triplication of a chromosome to a mongol child, other abnormalities to sex disorders, and yet others to mental disabilities.

The establishment of research fellowships at Harwell tenable for up to 3 years brought to the establishment many promising young scientists from the United Kingdom

and abroad, who would not otherwise have been attracted by a Civil Service career. We took the first step to reduce the "brain drain" by sending out each year a "recovery mission" to interview scientists from the United Kingdom working in the United States and Canada on fellowship appointments and, by offering research fellowships or permanent appointments, we were successful in inducing many to return. The Atomic Energy Authority has since been joined by the Central Electricity Generating Board and the Civil Service Commission in this annual recovery operation. Harwell staff have been appointed to about forty university professorships, twenty-nine of them in Britain, and through its Isotope School and Postgraduate Education Centre the establishment carries out important educational functions.

In spite of the achievements of competitive nuclear power in the advanced gas reactor series of nuclear power stations, the authority still has an important role in development. Not all the development problems of fast reactor power stations or steam generating heavy water reactor power stations are solved. The technology developed for the Dragon reactor project at Winfrith may lead to power stations of still higher efficiency working perhaps with high power gas turbines, and its coated particle fuels may be used in future advanced gas-cooled reactor stations. The high "availability" of our nuclear power stations (85 per cent) reported by the chairman of the Central Electricity Generating Board reflects the strong research and development effort of the past.

Nevertheless the research and development effort in atomic energy is being reduced and transferred partly to other non-atomic energy problems. Harwell's interdisciplinary strength is to be used to establish a ceramics centre and a non-destructive testing centre, and a recent Harwell conference showed the possibility of contributing to the exploitation of the resources of the ocean. The Minister of Technology recently spoke with admiration of the role of US research institutes such as Battelle. Part of the authority's great technological strength could be used for similar purposes.

# Peptide Synthesis from Hydrogen Cyanide and Water

by

CLIFFORD N. MATTHEWS  
ROBERT E. MOSER

Central Research Department,  
Monsanto Company,  
Saint Louis, Missouri

Did primitive proteins arise directly from simple inorganic molecules? Experiments show hydrogen cyanide polymers react with water to produce peptides containing at least twelve  $\alpha$ -amino-acids.

It has long been known that base-catalysed polymerization of hydrogen cyanide yields mixtures of solid products which include a tetramer—diaminomaleonitrile—and black intractable polymers believed to have fused tetrahydropyridine structures<sup>1</sup>. Recently, adenine and related imidazoles have also been detected<sup>2-4</sup>. In this paper we describe the synthesis from hydrogen cyanide of yet a further class of compounds—polymers that are readily converted by water to peptide like solids<sup>4</sup>.

In a typical experiment, freshly distilled hydrogen cyanide (500 g) and anhydrous liquid ammonia (5 g) were introduced into an evacuated 1 l. 'RB' flask capped with a ground glass joint connected through a vacuum stopcock to an exit tube. On standing at room temperature<sup>5</sup>, the colourless liquid slowly darkened, to become yellow, orange and then brown-black as a solid gradually deposited. After 4 weeks unreacted cyanide and ammonia were removed under vacuum, leaving a dark solid residue (270 g). A sample removed for elemental analysis gave carbon, 44.48; hydrogen, 3.99; nitrogen, 52.47 per cent. Theoretically hydrogen cyanide should contain carbon, 44.44; hydrogen, 3.73; nitrogen, 51.83 per cent. After stirring a portion of the dark solid (38 g) with cold water (250 ml.) and filtering off a solid black residue on a layer of filter paper pulp, the dark filtrate was freeze-dried to a brown solid.

This material (2.0 g) was dissolved in water, further clarified by filtration through a short column of 'Sephadex' resin (G-15, 4.5 × 20 cm), and freeze dried to a yellow-brown solid (1.3 g). Separation of this mixture was carried out using a longer 'Sephadex' column (G-15, 2.5 × 90 cm) with ammonium acetate buffer (ionic strength 0.01). Portions of the eluted solution (3 ml.) were collected

automatically, the concentration of material in each sample was followed spectrophotometrically at 230 m $\mu$  and recorded in the form of an elution diagram (Fig. 1). The collected solutions were combined into three fractions which were freeze dried to give yellow brown solids 4A (220 mg), 4B (120 mg) and 4C (65 mg). 4B was shown to be essentially pure diaminomaleonitrile by its infra-red spectrum, by recrystallization to give yellow crystals (melting point 182°–184° C) and by the chromatogram obtained following automatic peptide analysis<sup>6</sup>. The comparable chromatograms of 4A and 4C (Fig. 4) showed that each solid contained a mixture of peptidic material and virtually no free  $\alpha$ -amino-acids. For example, the peaks on the upper curve of chromatogram 4A at 2, 2.6, 2.8, 3.8 and 5.2 h show greater absorptions than the corresponding points on the lower curve, indicating the presence of peptides<sup>6</sup> in 4A. Colour tests<sup>7</sup> established that no hydrogen cyanide tetramer was present. The infra red spectra of 4A and 4C exhibited peaks at 2,250 cm<sup>-1</sup> and 1,660 cm<sup>-1</sup>, showing the presence of nitrile and imino/ketone groups. Elemental analysis for 4A gave carbon, 39.1; hydrogen, 4.77; nitrogen, 38.35 per cent, and for 4C gave carbon, 40.7; hydrogen, 4.58; nitrogen, 43.45 per cent. The weight average molecular weight of 4A was 620. Hydrolysis (6 normal hydrochloric acid at 100° C for 24 h) of 4A, 4B and 4C followed by automatic  $\alpha$ -amino-acid analysis showed that each hydrolysate consisted of ammonia and glycine with lesser amounts of several other  $\alpha$ -amino-acids; at least ten amino-acids were detected in 4C (Table 1).

In a variation of the anhydrous polymerization reaction, the initial black solid product was boiled with water for 24 h and then worked up as before. Solutions corre-

Fig. 1. Elution diagram ('Sephadex G-15' column: ammonium acetate buffer, ionic strength 0.01) for fractionation of peptidic products (A-C) obtained from HCN-NH<sub>3</sub> polymerization followed by treatment with cold water (25°).

sponding to seven major peaks in the resulting elution diagram (Fig. 2) were freeze dried to give six yellow brown solids (5A-5G; samples 5F and 5G were combined). Automatic peptide analysis (Fig. 5) showed that each solid contained mixtures of peptidic material and no diaminomaleonitrile. Appreciable amounts of glycine were also present in 5A and 5C (see parallel peaks at 5 h), as had been indicated by prior ninhydrin tests using thin-layer chromatography. Hydrolysis (6 normal hydrochloric acid at 100° C for 24 h) of the six solids yielded mixtures of glycine and several other  $\alpha$ -amino-acids (Table 1). Clearly, boiling had modified the peptidic products and had converted diaminomaleonitrile to other peptide like solids and to glycine. Parallel experiments<sup>8</sup> showed that when pure diaminomaleonitrile was boiled in water for 24 h and subjected to the separation procedures previously used, four yellow brown solids were obtained, each containing peptidic mixtures, with glycine also being found in two of the samples. Cold water had no effect on the tetramer.

In another series of experiments, hydrogen cyanide (1.5 mole, 41 g) was added to an aqueous solution of ammonia (1.0 molar, 100 ml.) in a stoppered 1 l. 'RB' flask cooled by an iced water bath. The darkening mixture was stirred magnetically for 4 h and was then packed in ice and kept in a refrigerator for 4 days. The resulting black slurry was diluted with water, flushed with nitrogen for 4 h to remove unreacted hydrogen cyanide and ammonia, and then filtered to remove a black residue. The black filtrate was worked up as before to give four solutions (Fig. 3) which were freeze dried to yellow brown solids (6A-6D). 6D was shown to be diaminomaleonitrile. Automatic peptide analysis (Fig. 6) showed that 6A, 6B and 6C contained mixtures of amino-acid polymers

and virtually no free  $\alpha$ -amino-acids. Hydrolysis (6 normal hydrochloric acid at 100° C for 24 h) of each of the four solids gave mixtures of up to twelve  $\alpha$ -amino-acids (Table 1).

Control experiments with 'Sephadex' columns showed that many cyano compounds are strongly retained by the resins. As a result, elution of the complex peptide-like mixtures does not take place in a systematic way related to molecular size. The peptidic solids apparently remain

All results have been adjusted to read  $\mu$ moles  $\alpha$ -amino-acid/g hydrolysate.

admixed with other products, as shown by the fact that, after hydrolysis, yields of  $\alpha$ -amino-acids are not quantitative. The several kinds of evidence that have already been discussed, however, are consistent with our conclusion that the polymers (or segments of the polymers) have peptidic structures. Thin-layer chromatographic ninhydrin tests<sup>4</sup> indicate the absence of monomers such as  $\alpha$ -amino-acids and related amides and amidines, dinitrophenylation experiments<sup>4</sup> point to the presence of peptide linkages and automatic  $\alpha$ -amino-acid analysis shows that mixtures of  $\alpha$ -amino-acids are present after hydrolysis. Automatic peptide analysis suggests that mixtures of peptides are present before hydrolysis, while molecular weight determinations confirm the polymeric nature of the products.

These experiments show that base-catalysed polymerization of hydrogen cyanide yields polymers which are converted by water to peptidic solids. The water can be added to the anhydrous products or can be introduced as a solvent for the reaction. Other products<sup>1-4</sup> present include diaminomaleonitrile, adenine and azulmin—black, intractable polymeric material. Current ideas of the structure of the black polymer need to be reconsidered because previously studied samples of azulmin formed in non-aqueous solvents must have contained polymeric peptidic precursors. As a result, nitrile groups of these peptidic polymers, detected by infra-red spectroscopy, have been wrongly attributed to the black solids. Direct synthesis of  $\alpha$ -amino-acids does not take place. Their presence under certain conditions is due to hydrolysis of primary reaction products including diaminomaleonitrile, adenine<sup>9</sup> and the peptidic solids.

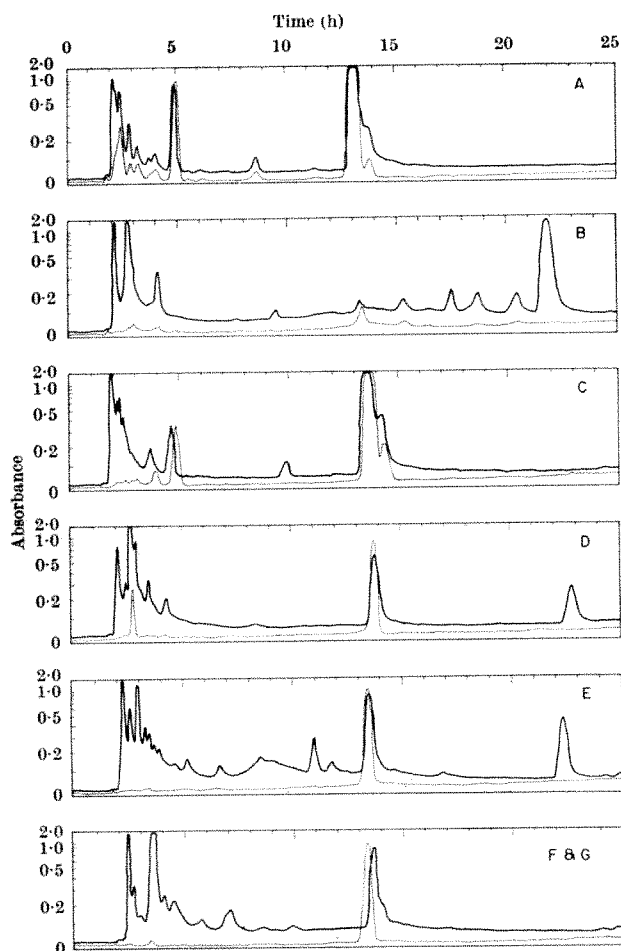

Fig. 5. Chromatograms of separated peptidic products (A-G) obtained from  $\text{HCN-NH}_3$  polymerization followed by treatment with boiling water, recorded before (lower curves) and after (upper curves) alkaline hydrolysis.

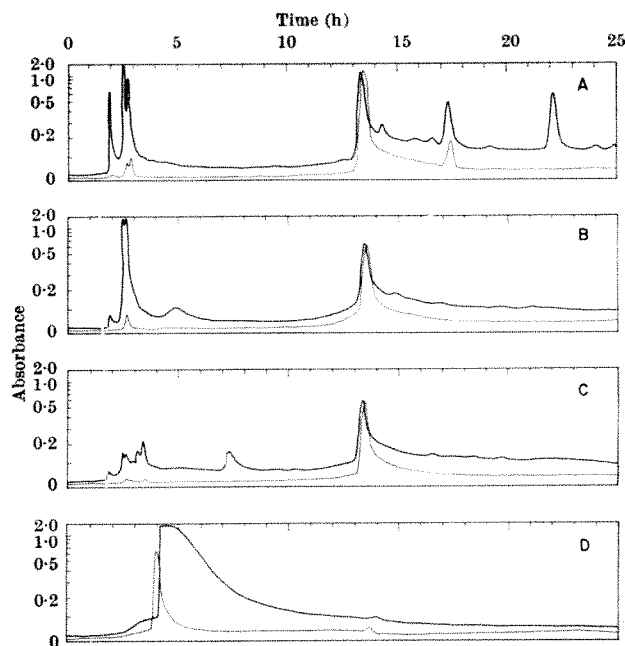

Fig. 6. Chromatograms of separated peptidic products (A-D) obtained from  $\text{HCN-NH}_3\text{-H}_2\text{O}$  polymerization followed by treatment with cold water (25°), recorded before (lower curves) and after (upper curves) alkaline hydrolysis.

Total hydrolysis of the peptidic solids yields up to fourteen known  $\alpha$ -amino-acids, assuming that the amide precursors of aspartic and glutamic acid were also formed. A few other ninhydrin reactive compounds present in trace amounts have not been characterized. So far, detection of proline, tyrosine, phenylalanine and tryptophan remains uncertain. The aromatic  $\alpha$ -amino-acids are not expected products of these reactions in the absence of acetylene or acetylene derivatives<sup>4</sup>. Of the twenty  $\alpha$ -amino-acid residues commonly found in proteins, lysine, histidine, arginine, aspartic acid, threonine, serine, glutamic acid, glycine, alanine, valine, isoleucine, leucine, probably asparagine and glutamine and possibly proline are thus products of spontaneous reactions involving only hydrogen cyanide and water<sup>10</sup>.

Fig. 7. Polypeptide synthesis from hydrogen cyanide and water. *R* represents 15 different  $\alpha$ -amino-acid side chains.

To account for the overall synthesis leading to peptides (Fig. 7) we propose<sup>4,11</sup> the following reaction sequence, starting with the dimerization<sup>10</sup> of hydrogen cyanide to aminocyanocarbene, a ground state singlet compound with considerable dipolar character<sup>12</sup> (Fig. 8).

Spontaneous polymerization of the dimer, followed by tautomerization and addition of hydrogen cyanide to the backbone double-bonds, then led to the formation of polyaminomalononitrile<sup>4</sup>. The activated nitrile groups of this polyamidine became further modified by cyanide attack<sup>10</sup> to give more complex side chains. Interaction of water with various projecting imino and cyano groups followed by decarboxylation finally yielded the peptide structures<sup>4</sup> (Fig. 9).

Alternatively, peptide synthesis in solution may have proceeded by anionic polymerization following the formation of an ambident anion<sup>13</sup> from aminocyanocarbene and a base (*B*) (Fig. 10).

Successive attack by the positively charged ends of aminocyanocarbene molecules on the unhindered<sup>13</sup> ketimine ends of growing anions then led to the polyketenimine

precursor of polyaminomalnonitrile (Fig. 10). The formation of this latter polymer by direct polymerization of aminomalnonitrile, a trimer of hydrogen cyanide highly unstable in water<sup>3</sup>, seems less probable than either of the two routes outlined here. That aminomalnonitrile decomposes to yield peptidic solids which can be further hydrolysed to mixtures of  $\alpha$ -amino acids<sup>14</sup> suggests that polymerization proceeds through hydrogen cyanide and its dimer rather than by way of the trimer.

In the context of studies of chemical evolution concerned with the origin of proteins<sup>15-18</sup> we conclude that in the many simulation experiments that have been carried out involving hydrogen cyanide as a starting material or reaction intermediate, peptide synthesis occurred spontaneously following the formation and modification of a hydrogen cyanide polymer with the structure of polyaminomalnonitrile. We therefore propose the following reinterpretations of the results of several types of pioneering experiments.

Mixtures of methane, ammonia and water (or comparable reducing mixtures) subjected to high energy radiations have yielded  $\alpha$ -amino-acids<sup>15-21</sup> and, in some cases, materials like peptides<sup>20,21</sup>. It is usually assumed that the peptides are condensation products of  $\alpha$ -amino-acids that were first formed by the well known Strecker route from  $\alpha$ -aminoacetonitriles. It appears far more likely to us that the hydrogen cyanide formed from the reactants gave rise to polyamides which reacted with water to yield peptides. Under the extreme conditions used, these became wholly or partially hydrolysed to  $\alpha$ -amino-acids. To support this view we have shown<sup>4</sup> that polymeric peptide precursors, synthesized by applying electric discharges to mixtures of methane and ammonia, are converted by water to peptide like solids.

It has been proposed<sup>22-24</sup> that the formation of triglycine from aminoacetonitrile (by heating with kaolinite and extracting with water)<sup>22</sup> shows how proteins could have originated from polyamides assumed to have been

synthesized by condensation between amine and nitrile groups. It seems more probable to us that in these experiments this unstable nitrile decomposed rapidly to hydrogen cyanide and ammonia. Polymerization and contact with water then yielded peptides. Even at room temperature, aminoacetonitrile falls apart rapidly in air or in water to give a black solid and other products which we have shown (unpublished results) can be hydrolysed to a mixture of  $\alpha$ -amino-acids.

Reactions of hydrogen cyanide in water catalysed by bases, investigated under various conditions by a number of workers<sup>1,25-27</sup>, have been reported to yield  $\alpha$ -amino-acids. We think that these products were formed by hydrolysis of peptides and hydrogen cyanide oligomers (diaminomaleonitrile and adenine) during the course of the reactions.  $\alpha$ -Amino-acid polymers detected in ammoniacal cyanide solutions at 90° C were assumed to have condensed from free  $\alpha$ -amino-acids, particularly as added labelled methionine was incorporated into the polymeric materials<sup>26</sup>. While some condensation would be expected at these high temperatures<sup>23</sup>, the results of our anhydrous and aqueous polymerization studies led us to conclude that most of the peptidic products arose directly from hydrogen cyanide, supplied both as a starting material and by decomposition of diaminomaleonitrile<sup>8</sup>. We consider<sup>4,11</sup> polycondensation of  $\alpha$ -amino-acids under high temperature, anhydrous or acidic conditions<sup>15-18</sup> to be irrelevant to the question of the origin of proteins.

In the reducing environment of primeval times direct synthesis of polypeptides would have been highly favoured as hydrogen cyanide was certainly a major component of the atmosphere<sup>11</sup>. We suggest that after polymerization and modification in the presence of other reactive molecules such as hydrogen sulphide and acetylene<sup>4</sup>, the prototypes of today's proteins were formed after the macromolecules settled into the cold<sup>3,11</sup> oceans. As the process of molecular evolution continued, this protein-dominated material gave rise to protein-directed life.

<sup>10</sup> We assume that the various hydrogen cyanide reactions discussed in this paper are subject to general base catalysis or initiation, the most likely bases involved being cyanide ion, ammonia and hydroxide ion. Photochemical activation would also be feasible.

## Regulation of Nitrate Reduction in *Aspergillus nidulans*

by

J. A. PATEMAN\*

D. J. COVE

Department of Genetics,  
University of Cambridge

Production of nitrate reductase may be under the control of a regulator gene with a product which can exist as an inducer or a repressor.

NITRATE is readily utilized as a source of nitrogen by plants and many kinds of micro-organisms. It is generally accepted that the initial stages of utilization are the reduction of nitrate to ammonium as follows

The enzymes known to be involved in this pathway in many organisms are nitrate reductase, nitrite reductase and hydroxylamine reductase. The identity of the intermediates between nitrite and ammonium and the enzymes responsible for the reactions is not known for certain. It is probable that in some higher plants<sup>1</sup> and in *Aspergillus nidulans* only two enzyme proteins are involved. These are nitrate reductase and nitrite reductase, which in *A. nidulans* probably also exhibits hydroxylamine reductase activity<sup>2</sup>. These enzyme activities in *A. nidulans* are induced by nitrate and nitrite and repressed by ammonium<sup>2–4</sup>. The following relevant types of mutants affecting the utilization of nitrate are known in *A. nidulans*<sup>2</sup>. The *nia D* locus is probably the structural gene for nitrate reductase; *nia D* mutants lack normal nitrate reductase activity and cannot utilize nitrate as a nitrogen source. The *nii A* locus is probably the structural gene for nitrite and hydroxylamine reductase; *nii A* mutants possess normal inducible nitrate reductase, lack nitrite and hydroxylamine reductase activity and cannot utilize nitrate or nitrite. The *nii B* gene is probably a regulator gene concerned with the induction of the nitrate reducing enzymes; *nii B* mutants lack nitrate, nitrite and hydroxylamine reductase activities and cannot utilize nitrate or nitrite.

The *nii A* mutants possess inducible nitrate reductase and lack nitrite reductase activity, and so when *nii A* strains are grown on urea as a nitrogen source and with nitrate also present, nitrite accumulates in the mycelium and is also excreted into the medium (unpublished work

of Pateman). This property of the *nii A* mutants permits recognition of mutants which are constitutive with respect to the synthesis of nitrate reductase. The essentials of the method are as follows. Conidia from an *nii A* strain are treated with a mutagen—nitrosoguanidine was used in the experiments reported here—and plated on agar medium containing 0.08 per cent sodium deoxycholate with urea as the nitrogen source. The resultant colonies are replicated<sup>5</sup> onto a second set of medium containing urea as the sole nitrogen source.

The resultant replica colonies, while they are still actively growing, are treated with a solution of sodium nitrate for 5–10 min. The colonies are tested for the presence of nitrite using a modification of the colorimetric method of Nason and Evans<sup>6</sup>, which provides a very sensitive test for nitrite, the presence of which is indicated by a purple colour. Normal *nii A* colonies do not stain purple in these conditions. If any of the replica colonies turn purple, indicating the presence of nitrite in the mycelium, the original colony on the master plate can be traced and is available for investigation.

The rationale for the technique is based on the observation that *nii A* colonies in appropriate conditions require a total of 20–25 min for nitrate to be taken up, the induction of nitrate reductase and subsequent production of a detectable quantity of nitrite. Consequently an *nii A* mutant constitutive for nitrate reductase should produce detectable nitrite after a shorter period of nitrate than is required by an inducible *nii A* strain. This proves to be the case and a number of constitutive *nii A* mutants have been isolated by this method. We report here some of the biochemical and genetical characteristics of one of those constitutive mutations designated *nir*<sup>c</sup> to indicate a constitutive mutation in a regulator gene for the nitrate reductase pathway.

The strains were grown for enzyme assay in shaken culture at 25° (ref. 7). The procedures for the various enzyme assays have been given before<sup>2</sup>. *nii A* *nir*<sup>c</sup>: The

<i>nir<sup>c</sup>/niiB<sub>1</sub></i>	58	30	47	108	109	149

All enzyme activities are expressed as  $\mu$ moles of substrate transformed/min/mg of protein.

constitutive mutation *nir<sup>c</sup>* was induced in an *niiA<sup>-</sup>* strain, so that it possessed nitrate reductase but not nitrite or hydroxylamine reductase activity. The *niiA<sup>-</sup> nir<sup>c</sup>* strain was grown on various nitrogen sources and the nitrate reductase activity determined. The results are given in Table 1. The *niiA<sup>-</sup> nir<sup>c</sup>* strain is fully constitutive for nitrate reductase and when grown on urea or uric acid produces concentrations of nitrate reductase equivalent to those produced on urea plus the co-inducer nitrate. In the prototroph *niiA<sup>+</sup> nir<sup>+</sup>* and the mutant *niiA<sup>-</sup> nir<sup>+</sup>* nitrate reductase is only produced in a high level concentration after growth in the presence of nitrate. The constitutive mutant *niiA<sup>-</sup> nir<sup>c</sup>* no longer requires nitrate for induction but it is still subject to repression by ammonium in a similar fashion to a strain wild type with respect to its nitrogen metabolism and the *niiA<sup>-</sup> nir<sup>+</sup>* mutant.

A strain of *nir<sup>c</sup>* was obtained from a cross between the wild type and the *niiA<sup>-</sup> nir<sup>c</sup>* mutant. The *nir<sup>c</sup>* strain is wild type with respect to all the structural genes concerned with nitrate utilization but carries the constitutive mutation at the *nir* locus. This strain, together with the wild type, was grown on various nitrogen sources and the nitrate, nitrite and hydroxylamine reductase activities were determined. The results are given in Table 1. The *nir<sup>c</sup>* mutant is constitutive for nitrate reductase. The levels of activity of this enzyme in *nir<sup>c</sup>* are similar in mycelium grown on urea or on urea plus nitrate and rather higher than those of *nir<sup>+</sup>* grown on urea plus nitrate. The situation with respect to nitrite and hydroxylamine reductase activity is different. When *nir<sup>c</sup>* is grown in the absence of the co-inducer nitrate, the levels of nitrite and hydroxylamine reductase activity are about 50 per cent of those of *nir<sup>+</sup>* when it is grown in the presence of nitrate. When *nir<sup>c</sup>* is grown on urea plus nitrate the nitrite and hydroxylamine reductase activities are typically two to three times higher than those of *nir<sup>+</sup>* grown on urea plus nitrate. Thus the constitutive mutation in the *nir* gene results in semi-constitutivity in the absence of co-inducer and super-inducibility in the presence of co-inducer for nitrite and hydroxylamine reductase activity.

To investigate the dominance relationship of the *nir<sup>c</sup>* and *nir<sup>+</sup>* alleles the following diploid strains were made: the homozygous diploid constitutive strain *nir<sup>c</sup>/nir<sup>c</sup>*; the heterozygous diploid carrying both *nir<sup>c</sup>* and *nir<sup>+</sup>* alleles, *nir<sup>c</sup>/nir<sup>+</sup>*; and the homozygous diploid wild type *nir<sup>+</sup>/nir<sup>+</sup>*. These diploid strains were grown on various nitrogen sources, and their enzyme activities were determined. The results are given in Table 1. The *nir<sup>c</sup>/nir<sup>c</sup>* diploid is similar to the haploid *nir<sup>c</sup>* and the *nir<sup>+</sup>/nir<sup>+</sup>* diploid is similar to the haploid *nir<sup>+</sup>*. The nitrate reductase

activity of the heterozygous diploid *nir<sup>c</sup>/nir<sup>+</sup>* when grown on urea alone is about 50 per cent of that possessed by the haploid *nir<sup>+</sup>* or diploid *nir<sup>+</sup>/nir<sup>+</sup>* prototrophs when grown on urea plus nitrate. That is, the *nir<sup>c</sup>* allele is functionally semi-dominant with respect to the regulation of the synthesis of nitrate reductase. The nitrite and hydroxylamine reductase activities of *nir<sup>c</sup>/nir<sup>+</sup>* when grown on urea alone are very low, but are significantly higher than those of the wild type *nir<sup>+</sup>/nir<sup>+</sup>* on urea. Thus the *nir<sup>c</sup>* allele is almost completely recessive with respect to the regulation of nitrite and hydroxylamine activity. The level of activity of the two enzymes in *nir<sup>c</sup>/nir<sup>+</sup>* is less than that of the wild type diploid when both are grown on urea plus nitrate. This result was obtained with all three separate heterozygous diploids tested; its significance, if it is a genuine characteristic of such diploids, is not clear.

Genetic evidence—see following—suggests that the *nir<sup>c</sup>* mutation is in the *niiB* gene. Consequently, a diploid *nir<sup>c</sup>/niiB<sub>1</sub>* was made, grown on various nitrogen source and assayed for the nitrate utilizing enzymes. The results given in Table 1 are similar to those obtained for the *nir<sup>c</sup>/nir<sup>+</sup>* diploid.

The presence of ammonium represses the synthesis of the nitrate utilizing enzymes in the wild type. The haploid constitutive strain was grown on three types of medium containing, respectively, 0.015 molar ammonium tartrate, 0.015 molar ammonium tartrate plus 0.01 molar sodium nitrate and 0.015 molar ammonium tartrate plus 0.1 molar sodium nitrate. The enzyme activities of the *nir<sup>c</sup>* and *nir<sup>+</sup>* strains grown in these conditions are given in Table 2. The constitutive strain is strongly repressed by ammonium but to a lesser degree than the wild type. Increasing the concentration of the co-inducer nitrate relieves the ammonium repression to some extent as it does with the wild type.

The original *niiA<sup>-</sup> nir<sup>c</sup>* mutant strain was detected because in the appropriate conditions an *niiA<sup>-</sup> nir<sup>c</sup>* colony accumulates nitrite and can be stained purple by the chemical test for nitrite. It was subsequently found that this staining procedure could be used to detect the presence of the *nir<sup>c</sup>* allele in the absence of the *niiA<sup>-</sup>* allele. In short, after growth on urea, and a brief treatment with nitrate, followed by the nitrite staining procedure, *niiA<sup>-</sup> nir<sup>c</sup>* colonies are a deep purple pink, *niiA<sup>+</sup> nir<sup>c</sup>* colonies are a faint pink and *niiA<sup>+</sup> nir<sup>+</sup>* colonies are white. Classification of these genotypes by a simple chemical test permits the genetic analysis of the segregation of the *nir* gene. The following crosses were set up. (a) *niiA<sup>+</sup> nir<sup>c</sup>*  $\times$  *niiA<sup>-</sup> nir<sup>+</sup>*. Only one of the recombinant genotypes, *niiA<sup>+</sup> nir<sup>+</sup>*, can be readily classified in this cross. A total of twelve *niiA<sup>+</sup> nir<sup>+</sup>* was present in a sample of seventy progeny. This indicates that the *niiA* and *nir* genes are about 35 cM apart on chromosome VIII. (b) *niiA<sup>-</sup> nir<sup>c</sup>*  $\times$  *niiA<sup>+</sup> nir<sup>+</sup>*. Both of the recombinant types, *niiA<sup>-</sup> nir<sup>+</sup>* and *niiA<sup>+</sup> nir<sup>c</sup>*, can be classified in this cross. A total of fifty-five recombinants was found in a sample of 123 progeny. This indicates that the *niiA* and *nir* genes are about 45 cM apart on chromosome VIII. (c) *niiB<sup>+</sup> nir<sup>c</sup>*  $\times$  *niiB<sup>-</sup> nir<sup>+</sup>*. Only the recombinant type *niiB<sup>+</sup> nir<sup>+</sup>* can be readily classified in this cross. A total of 627 progeny were analysed from this cross and two of them were the *niiB<sup>+</sup> nir<sup>+</sup>* recombinant type. It is possible, although unlikely, that these two apparent recombinants were contaminants. The data demonstrate, however, that the *nir*

All enzyme activities are expressed as  $\mu$ moles of substrate transformed/min/mg of protein.

gene is either identical with the *nii B* gene or, if there are two genes, they are closely linked.

The experiments reported here show: (1) the *nir*<sup>c</sup> mutation affects all the known enzyme activities thought to be concerned with nitrate reduction in *A. nidulans*; (2) the *nir*<sup>c</sup> mutation is semi-dominant with respect to the induction of nitrate reductase and recessive with respect to the induction of nitrite and hydroxylamine reductase activities in the heterozygous diploid of genotype *nir*<sup>c</sup>/*nir*<sup>+</sup>; and (3) the *nir*<sup>c</sup> mutation is located in or very close to the *nii B* locus. We propose the following hypothesis on the basis of these observations and our previous work<sup>2,3,7,8</sup>.

There is a regulator gene which controls the induction of the enzymes responsible for nitrate reduction. The product of this regulator gene can exist in two forms, one of which represses, while the other is necessary for the synthesis of enzyme. In wild type strains, in the absence of co-inducer, the regulator product is in its repressor form. The co-inducer, which may be either nitrate or nitrite, combines with the regulator product, converting it to its other form, which we shall call an inducer. Mutation in the regulator gene can result in various different altered regulator substances. First, mutation could lead to the complete inability to make a regulator substance. Second, a regulator substance could be produced, which cannot be converted to its inducer form by the co-inducer. The *nii B*<sup>-</sup> mutants, of which some eighteen are known, are probably examples of these first two types of mutations. Third, an altered regulator product could be made, which even in the absence of co-inducer has some of the properties of the inducer. Mutant strains producing such a regulator substance would be constitutive and it is proposed that *nir*<sup>c</sup> is such a strain. There are a number of points concerning this hypothesis which merit further discussion.

In contrast to the classical case of the *i* gene of the  $\beta$ -galactosidase system of *E. coli*<sup>9</sup>, the product of the *nir* gene is assumed to play not only a negative but also a positive role in the induction of nitrate and nitrite reductases. This positive role is inferred from the dominance of the *nir*<sup>c</sup> allele. It is also possible to explain dominant constitutive mutations without invoking a

positive control system by constructing elaborate cascade models, but such a hypothesis would need to be considerably more complex than the one proposed to explain all the findings in this system. Other examples are known of regulator genes which exhibit some degree of dominance; these include a regulator gene for xanthine dehydrogenase in *Aspergillus nidulans*<sup>10</sup>, and the *C* gene in the L-arabinose system of *E. coli*<sup>11</sup>.

We propose that the product of the *nir*<sup>+</sup> gene plays a negative as well as a positive regulatory role, in order to accommodate the finding that the *nir*<sup>c</sup> allele is not fully dominant. The situation is best envisaged as follows. The product of the *nir*<sup>+</sup> allele acts as a repressor, but its inducer form, that is, when it is combined with co-inducer, is necessary to actively initiate enzyme synthesis. The product of the *nir*<sup>c</sup> allele is, however, able to initiate synthesis, even in the absence of co-inducer. In the *nir*<sup>+</sup>/*nir*<sup>c</sup> diploid in the absence of co-inducer, there is competition between the *nir*<sup>+</sup> product, which functions as a repressor, and the *nir*<sup>c</sup> product, which functions as an inducer, and consequently enzyme activities intermediate between the two homozygotes are found.

It must be supposed that the interaction between the structural gene and the regulator gene product is somewhat different for the nitrate and nitrite reductase structural genes. The *nir*<sup>+</sup>/*nir*<sup>c</sup> heterozygous diploid produces in the absence of co-inducer about 40 per cent of the nitrate reductase but only 10 per cent of the nitrite reductase activity which it produces in the presence of co-inducer. It therefore seems that the affinity of the *nir*<sup>c</sup> product for the recognition site of the nitrite reductase structural gene is less than its affinity for the recognition of the nitrate reductase structural gene. Furthermore, the increased synthesis of nitrite reductase in the presence of the co-inducer nitrate, compared with that in its absence, can be interpreted as indicating that the *nir*<sup>c</sup> allele product can interact with nitrate to become a better inducer substance. The principal features of the hypothesis proposed are represented diagrammatically in Fig. 1. Because the structural genes, *nii D* and *nii A*, are 10 cM apart<sup>2</sup>, there can be no operon organization for the nitrate reductase pathway. The situation with regard to the control of these enzymes, however, must be more complex. This

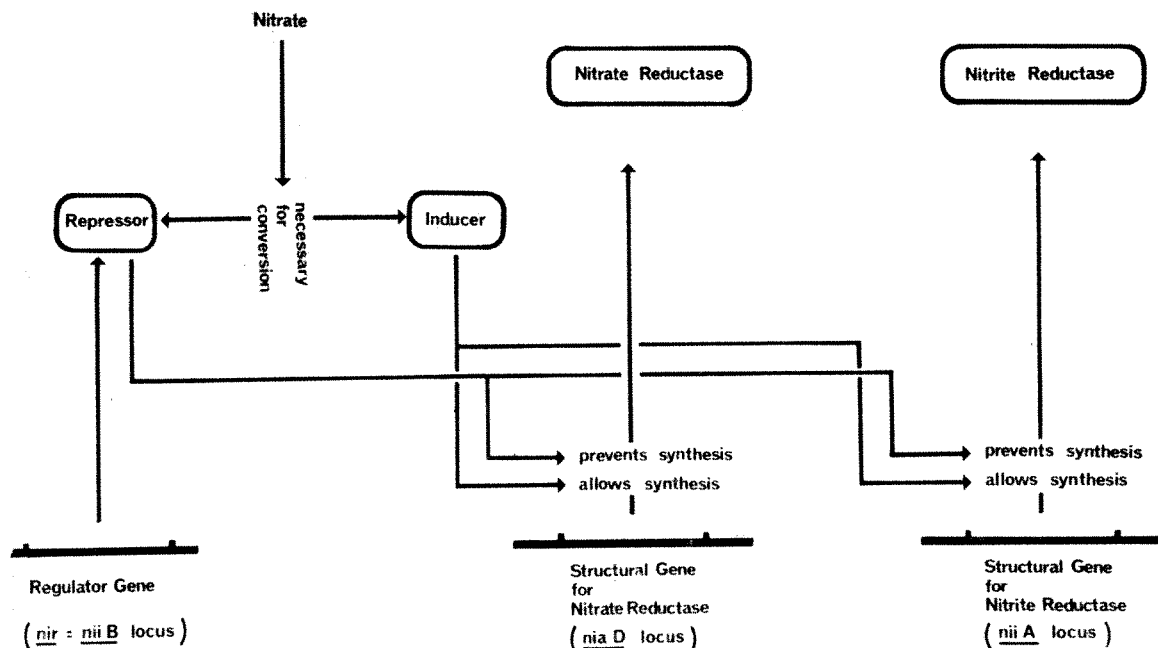

Fig. 1. A model illustrating the simplest hypothesis to account for the action of the regulator gene *nir*. The product of the regulator gene *nir* can exist in a repressor or inducer form depending on the presence of the co-inducer nitrate. When the regulator substance is in the inducer form, it has a positive action necessary for the initiation of enzyme synthesis. In the repressor form it prevents enzyme synthesis.

model does not prejudge at what stage gene action is controlled and takes no account of the repression of nitrate and nitrite reductase synthesis by ammonium, which can largely overcome the action of the co-inducer nitrate. Also there is a considerable body of evidence which suggests that nitrate reductase is itself a component in the control of the pathway. Some of the evidence for this and the resultant necessary modifications will be described elsewhere.

If the foregoing hypothesis is largely correct and the mutations, previously known as *nii B*<sup>-</sup>, do result in the production of a defective regulator substance, the following predictions can be made. In some cases mutation will result in the production of a regular substance which no longer acts as an inducer but which still functions as a repressor. This mutant repressor could still be inactivated by the co-inducer. In the heterozygous diploid containing such an allele and the *nir*<sup>c</sup> allele, the concentrations of enzyme in the presence and absence of the co-inducer will be similar to those of the *nir*<sup>c</sup>/*nir*<sup>+</sup> heterozygous diploid. The diploid between *nir*<sup>c</sup> and *nii B*<sup>-</sup> reported in this

article is an example of this. It should also be possible for mutation at the *nii B* locus to result in the absence of regulator substance or a regulator substance which is defective in both inductive and repressive functions. Such a mutation, when present in a heterozygous diploid with the *nir*<sup>c</sup> allele, should be completely recessive and the diploid should be completely constitutive in phenotype. At present a survey is being made of the known *nii B*<sup>-</sup> mutations in order to discover if any are completely recessive to *nir*<sup>c</sup>.

## Half-lives of Peptides and Amines in the Circulation

by

S. H. FERREIRA\*

J. R. VANE

Department of Pharmacology,  
Institute of Basic Medical Sciences,  
Royal College of Surgeons of England,  
London, WC2

The blood-bathed organ technique, which allows the continuous bioassay of substances in the circulating blood, has been used to measure the half-lives of several substances in the circulation.

THE half-life of a hormone in the circulating blood has usually been measured by one of two methods. In one, blood samples are taken after injection or infusion of the substance, and its concentration in the plasma is then estimated chemically or by bioassay<sup>1-4</sup>. This sampling technique is limited by its intermittent nature, the large doses of the substance that have to be given to achieve measurable concentrations in a small blood sample and the possibility that the removal of blood will itself affect the concentration of the substance or lead to a progressive alteration of the animal's physiology. In the other method, the physiological response to the hormone is used as an indicator of its concentrations in the circulation<sup>5</sup>. This method is limited by the assumption that the response will persist as long as the hormone is present in the circulating blood. Two illustrations show that this assumption is questionable. First, in the rat, the blood pressure response to noradrenaline declines during its continuous infusion; by contrast the vasoconstrictor response in the hind quarters is maintained even 1 h after the end of infusion<sup>6</sup>. Second, the anti-diuretic effects of analogues of vasopressin outlast the presence of the peptides in the circulation<sup>7,8</sup>.

A technique which employs a blood-bath organ<sup>9</sup> was developed to overcome some of these limitations. It permits continuous assay of many hormones at concentrations found after their release into the circulation<sup>10-12</sup>. We have applied this method to the determination of the half-lives of several substances in the circulation of cats and dogs.

Cats of either sex weighing 2-5 kg were anaesthetized with ethyl chloride and ether; anaesthesia was then maintained with chloralose (80 mg/kg intravenously). Dogs of either sex weighing 5-20 kg were anaesthetized

with halothane delivered from a Goldman vaporizer; anaesthesia was maintained with chloralose (100 mg/kg intravenously) and supplemented when necessary with pentobarbitone (5-10 mg/kg intramuscularly or intravenously). The trachea was cannulated and the lungs were ventilated mechanically. Polyethylene cannulae were tied into a femoral or carotid artery and into a femoral or jugular vein for removal and replacement of blood. Mean arterial blood pressure was recorded on a Beckmann-Offner dynograph using a Statham pressure transducer (type P23Db) attached to a side arm of the arterial cannula.

The following organs were used to assay the different substances: for bradykinin, strips of cat jejunum<sup>13</sup>; angiotensin, the rat colon<sup>14</sup>; 5-hydroxytryptamine, adrenaline and noradrenaline, the rat stomach strip<sup>15</sup>. All of these isolated organs contracted in response to the test substance except the rat stomach strip which relaxed to adrenaline and noradrenaline. They were suspended in polypropylene chambers and superfused<sup>16</sup> in cascade with Krebs solution while the animal was being prepared; their movements were transduced by Ether strain gauges attached to auxotonic<sup>17</sup> levers and recorded on the dynograph. The initial load on the assay organs was 1-3 g.

Heparin (1,000 IU/kg) was injected intravenously and the assay organs were then superfused with arterial blood delivered by a roller pump at 10-15 ml/min. The blood was collected in a reservoir and returned to the animal either by gravity or through a second channel or roller pump. The assay organs were calibrated by infusing the substances directly into the blood stream just after it had left the animal; for example, an infusion of 10 ng/min into a flow of 10 ml/min gave a rise in concentration of 1 ng/ml.

Constant intravenous infusions of the substances produced responses of the isolated blood-bathed organs which increased during the first 1 or 2 min to a plateau,

\*Present address: Department of Pharmacology, Faculdade de Medicina de Ribeirão Preto, São Paulo, Brazil.

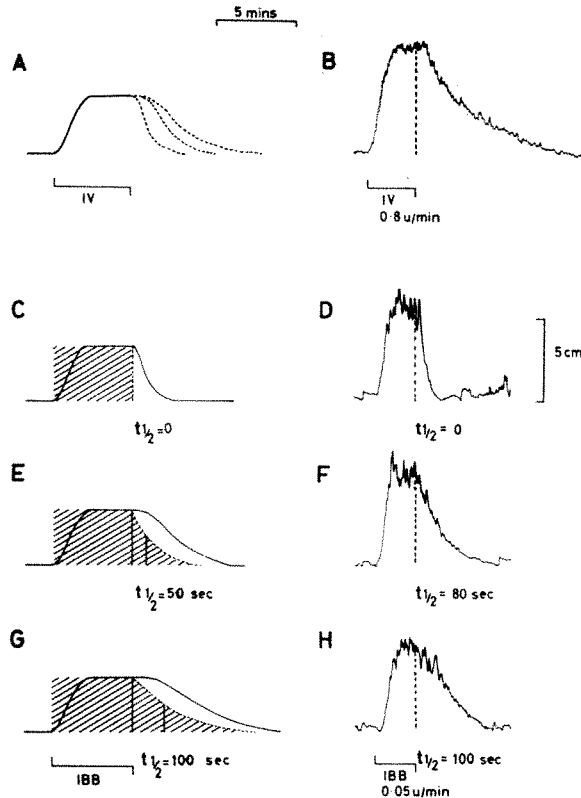

Fig. 1. The left hand side shows a diagram of the technique and the right hand side an actual tracing obtained using it. (A) Some possible patterns of relaxation of an assay organ after stopping an intravenous infusion. (C, E and G) Effects of infusions when given directly to the assay organs. (C) Infusion (shaded area) was stopped abruptly ( $t_{1/2} = 0$ ); (E) infusion was stopped with a half-time of 50 sec, and (G) with a half-time of 100 sec. The continuous line in each of these diagrams represents the contraction of the isolated organs. The right hand side of the figure is taken from an experiment in a cat in which a strip of cat jejunum was bathed with arterial blood. Kallikrein ( $0.8 \text{ u/min}$ ) was infused intravenously (B) or directly to the tissues with the infusion ( $0.05 \text{ u/min}$ ) ending with a half-time of 0 (D), 80 sec (F) and 100 sec (H). The decay of the contraction after intravenous infusion was longer lasting than after the calibrating infusion with a half-time of 100 sec.

which was then maintained for the duration of the infusion. When the infusion was abruptly stopped the response declined gradually (Fig. 1A and B). If the rate of decline of the effect depended only on the rate of decrease of drug concentration the half-life of the drug in the circulation could have been determined directly from the decay curve. The assay organs themselves, however, had a finite response time. An example of this is shown in Fig. 1C and D. In general, the return to baseline of the assay organs themselves had a half time varying from 5 to 50 sec, depending on the organ and on the drug.

After drugs are injected or infused, their concentration in the circulation tends to decline exponentially<sup>3,5,18,19</sup>. We therefore devised a method for infusing the substance directly into the assay system to produce an exponential decline in concentration. Infusions of the test substances were made into the blood bathing the assay organs with a roller pump<sup>20</sup>. The speed of the pump, and therefore the rate of infusion, was controlled by a 'Servomex MC 43' motor controller. Usually the speed of the motor controller of this system is regulated by a negative feedback voltage which can be set at any desired level. Our controller circuit was modified so that the feed-back voltage could be supplied, when desired, by a condenser discharging through a resistance so that the speed of the motor decayed exponentially. Condensers of different capacities were chosen to give exponential decays with half-times ( $t_{1/2}$ ) of 10, 15, 20, 45, 60, 85 and 100 sec.

Infusions were made into the blood bathing the assay organs, after it had left the animal, for long enough to

give a plateau response of the isolated organs. The infusions were stopped either abruptly ( $t_{1/2} = 0$ , Fig. 1D) or at different exponential rates (Fig. 1E, F, G and H) by the use of the condenser discharge system. The return to baseline of the assay tissues was progressively slower as the half-times of the exponential decay in the infusion rates were increased. To compensate for any variation in the height of the plateau response the rates of decline of the contractions of the assay organs were plotted as a percentage of the plateau response against time. This gave a family of curves which allowed discrimination between all the half-times used except 0 and 10 sec. The decline of the contraction of the assay organs after an intravenous infusion (Fig. 1A and B) was plotted in the same way. The resultant curve was compared with the family of curves to find the one which produced the closest match. The half-time of this curve was taken to be the half-life of the substance in the circulation. The figures show that the shapes of the curves were strikingly similar, confirming the validity of the underlying assumption that the decline in concentration after intravenous infusion was exponential.

The design of the experiments to find the half-life of bradykinins in the brain of the cat was as follows. First infusions of bradykinin were made into the bathing blood and intravenously to find infusion rates which gave similar contractions of the cat jejunum. In Fig. 2, the responses are to infusions of bradykinin ( $3 \text{ ng/ml}$  in the bathing blood) stopped instantaneously ( $t_{1/2} = 0$ , Fig. 2B), exponentially, with a half-life of 10 sec ( $t_{1/2} = 10$ , Fig. 2D) or of 15 sec ( $t_{1/2} = 15$ , Fig. 2A). Fig. 2C shows the effect of an intravenous infusion of bradykinin ( $5 \text{ ng/min}$ ). There was no change of blood pressure during infusion. In this and all other experiments, the infusions were given in random order. The graphs obtained by plotting the results of this experiment are shown in Fig. 2E. The decline of the response to a 10 sec half-time was not distinguishable from that of an instantaneous cessation of infusion, but the response to a 15 sec half-time was clearly

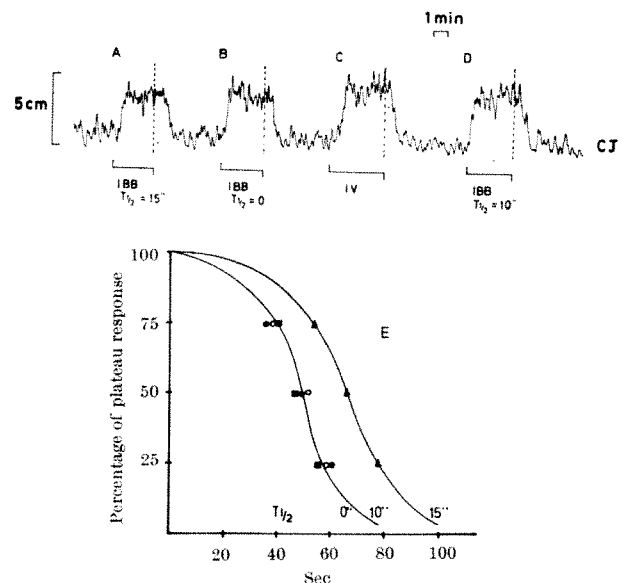

Fig. 2. The upper part of the figure shows contractions induced by infusing bradykinin either directly ( $3 \text{ ng/ml}$  IBB) to the cat jejunum strip bathed in arterial blood from a cat, or intravenously ( $5 \text{ ng/min}$ ) into the cat. The first effect (A) is a response to an IBB infusion which ends with a half-time of 15 sec, the second (B) with a half-time of 0 and the fourth (D) with a half-time of 10 sec. The third effect (C) is after the intravenous infusion. The vertical dotted lines are superimposed to show more clearly the end point of the infusion. The return to baseline of the contraction was plotted as a percentage of the plateau response in the graph below. It was difficult to separate the lines for  $t_{1/2} = 0$  (■) and  $t_{1/2} = 10$  sec (●) but  $t_{1/2} = 15$  sec (▲) was clearly distinguishable. The half-life of the intravenous infusion (○) lay within the 0 to 10 sec half-time range, showing that the half-life of bradykinin in this cat was less than 15 sec.

distinguishable. The intravenous infusion of bradykinin gave a curve which approximated to the instantaneous and 10 sec curves, showing that the half-life was certainly less than 15 sec. This was confirmed in two other experiments. Thus the half-life of bradykinin in the circulation is less than one circulation time. In man bradykinin has a half-life of less than 30 sec (ref. 3).

It should be noted that this technique detected changes in concentration of 1–5 ng/ml. To obtain such concentrations with intravenous infusions, infusion rates of 5  $\mu$ g/min had to be used, again suggesting that the removal of bradykinin from the circulation is very rapid.

Bradykinin is formed in the circulation by kallikrein, activated in the plasma or originating from tissues<sup>23,24</sup>. Although the half-life of bradykinin itself is short, it may continue to be formed in the circulation if kallikrein persists there in an active form. The blood-bathed organ technique was used to measure the half-life not only of the polypeptide but also of one of the enzymes which can liberate bradykinin. Kallikrein ('Glumorin', Farbenfabriken Bayer AG Leverkusen, Germany) was infused either directly into the bathing blood or intravenously into the cat in the same way as bradykinin. At the infusion rates used, kallikrein did not contract the cat jejunum bathed in Krebs solution, showing that the enzyme had no activity on this preparation. When bathed in blood, however, the cat jejunum contracted to infusions of kallikrein because of the generation of bradykinin. Thus the formation of bradykinin could be used to assess the presence of kallikrein. The contractions of a preparation of cat jejunum in response to infusions of kallikrein from one of four experiments in cats are shown in Fig. 1 and the curves plotted from these effects in Fig. 3. The half-life of kallikrein was slightly longer than that of the largest condenser discharge available (100 sec), and was estimated to be about 120 sec in this experiment. In two other experiments with the cat, the half-life was 100 sec and in the fourth it was many minutes. The half-life of kallikrein did not depend on its concentration in the plasma, for the same estimate was obtained after an infusion of 0.4 U/min given intravenously as was obtained after an infusion of 0.8 U/ml. given intravenously, although the faster infusion rate generated much more bradykinin. These rates of infusion of kallikrein were too slow to result in a decrease of blood pressure.

Angiotensin has a half-life in the circulation of the dog of less than 3 min<sup>10</sup>; its removal from the circulation is not caused by destruction in the blood stream, but it disappears in peripheral vascular beds<sup>25</sup>. This disappearance varies from 40 per cent in the hind quarters to 75 per cent in the kidneys, suggesting an overall value of about 50 per cent, or a half-life of angiotensin in the circulation of about one circulation time. In order to compare in the same animal the method of measuring the rate of disappearance with the method of measuring half-life the following experiment was carried out on a dog. The overall disappearance of angiotensin in one passage through the peripheral circulation was first established. A coaxial polyethylene catheter was passed down the right carotid artery and advanced retrogradely into the ascending aorta so that the tip of the inner catheter (external diameter 2 mm) lay just above the aortic valves. The outer catheter (external diameter 3 mm) was about 2 cm shorter than the inner one and therefore opened downstream with respect to the inner catheter. Blood for supplying the assay circuit was withdrawn through the inner catheter, so that it sampled the cardiac output. Infusions of angiotensin were made through the outer catheter, so that they mixed with the blood in the ascending aorta just after it had been sampled. Thus angiotensin reached the assay circuit only after it had passed once through the peripheral tissues. The blood-bathed rat colon was used to detect angiotensin, and the effects of infusions given through the arterial catheter were compared with the effects of infusions given intravenously.

Fig. 3. The lines are plotted from the return to base line of a cat jejunum preparation bathed in arterial blood from a cat, after kallikrein was infused either intravenously (for tracing, see Fig. 1B) or in calibrating doses IBB (Fig. 1, D, F and H). The return to base line after the infusions which ended with  $t_{1/2} = 0$  (■), 80 (●) and 100 (▲) sec were clearly distinguishable. The intravenous infusion (O) had a half-life of longer than 100 sec. In this experiment, two rates of intravenous infusion of kallikrein were used (0.4 and 0.8 U/min) but the curves for both lay on the same line.

The validity of comparison depends on the fact that no angiotensin disappears in the pulmonary circulation<sup>25</sup>. An arterial infusion of 0.5  $\mu$ g/min of angiotensin gave a plateau response of the rat colon which matched that produced by an intravenous infusion of 0.25  $\mu$ g/min: thus 50 per cent of the angiotensin infusion disappeared in passage from the arterial to the venous side of the circulation. In the same dog, infusions with different exponential declines were then made into the blood bathing the rat colons. The curves which were plotted were compared with those from the intravenous infusion (Fig. 4). The curve from the intravenous infusion matched almost exactly that with a 20 sec half-life, showing that in this dog the half-life was, indeed, about one circulation time. This experiment therefore demonstrates that the two methods give similar results and confirms the suggestion<sup>25</sup> that the half-life of angiotensin in the dog is about one circulation time.

The half-life of renin in the circulation is very much longer than that of angiotensin<sup>10,11,26</sup>, and probably exceeds 15 min. The present method could not be used to determine such a long half-life because condenser discharges of such duration could not be achieved. The error introduced by the delayed response of the assay organs, however, in comparison with such a long half-life is probably insignificant. Thus it may be possible to calculate the half-life of renin in the circulation of the dog simply by plotting the curve for the relaxation of the rat colon; this is being done (Ng and Vane, unpublished work).

Adrenaline is removed from the circulation by peripheral vascular beds<sup>27–29</sup>; for example, more than 90 per cent disappears in one circulation through the hind quarters<sup>27</sup>. A similar figure was obtained for noradrenaline<sup>27</sup>. Thus it might be expected that the half-life in the circulation would be less than one circulation time. This was confirmed in a cat (Fig. 4). An intravenous infusion of adrenaline gave a curve which matched the 10 sec half-life curve and an infusion of noradrenaline gave a curve which lay between the 0 and 15 sec half-life curve. A half-life of less than one circulation time was also obtained in a dog.

Unlike the catecholamines, 5-hydroxytryptamine is chiefly removed from the circulation by the lungs<sup>30–32</sup> and 90–98 per cent of an intravenous infusion disappears in one passage through the pulmonary circulation (Thomas and Vane, unpublished work). That 5-hydroxytryptamine

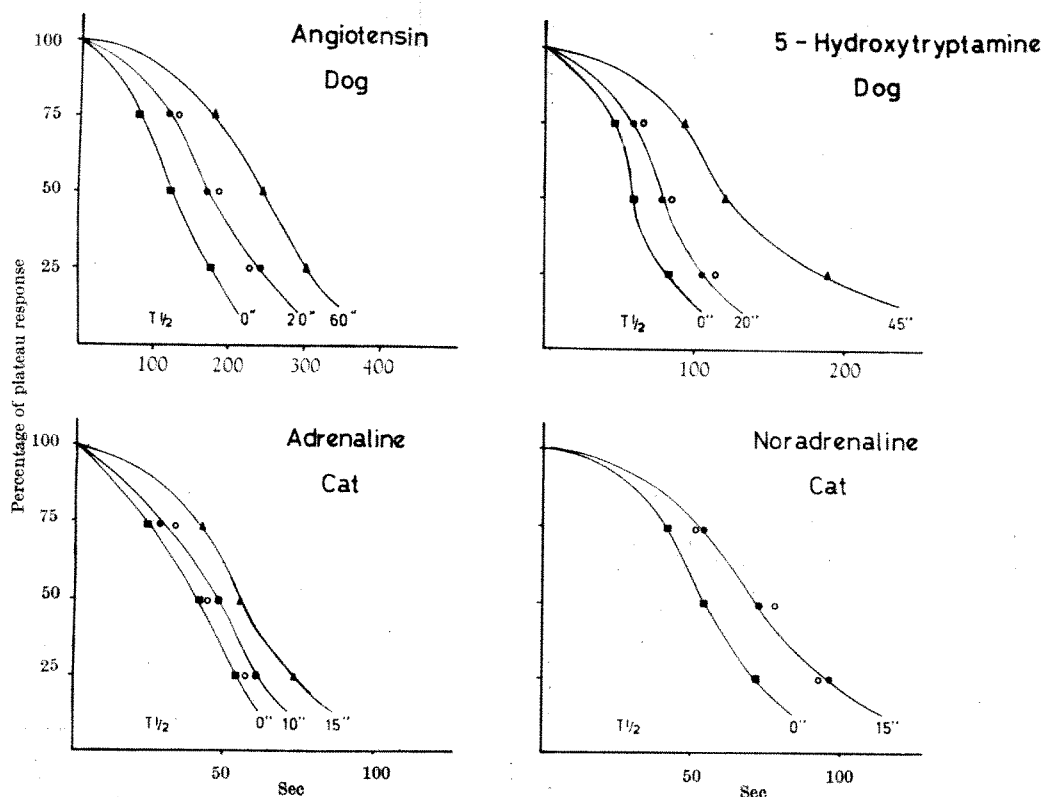

Fig. 4. The graphs are plotted from experiments with angiotensin, 5-hydroxytryptamine, adrenaline and noradrenaline. The half-lives of intravenous infusions (○) of these substances were 20 sec for angiotensin in the dog, 20 sec for 5-hydroxytryptamine in the dog, between 0 and 10 sec for adrenaline and 15 sec for noradrenaline in the cat.

has a half-life in the circulation of less than one circulation time was confirmed in a dog experiment (Fig. 4D).

To summarize our results: the way in which the contractions or relaxations of the blood-bathed assay organs return to baseline after an intravenous infusion can be exactly mimicked by stopping an infusion directly to the organs in an exponential fashion. This must mean that when an intravenous infusion is terminated, the concentration of hormone declines exponentially, even though the relaxation of the assay organ itself does not describe an exponential curve, presumably because it represents the addition of two exponential functions. For bradykinin, angiotensin, adrenaline, noradrenaline and 5-hydroxytryptamine, we found that the half-life in the circulation was less than or about equal to one circulation time. Thus when any of these substances are released or infused into the blood stream, the concentration will be reduced to about 10 per cent within three circulations. It is interesting that all of these naturally occurring substances, some of which have important hormonal functions, have such a short half-life in the circulation, although their method of removal from the circulation differs.

The enzymes kallikrein and renin have much longer half-lives; thus, just as for the renin-angiotensin system, it is likely that for bradykinin to have any importance as a circulating substance in physiological or pathological conditions the generating enzyme itself must be released into and circulate in the vascular system.

Finally, we must stress that we have measured the half-lives of these substances in the circulation; this may not reflect the half-lives of their activity in particular vascular beds. It is possible that each substance is inactivated by a different mechanism at a different rate, once it has left the circulation. As far as their effects on the pre-capillary resistance vessels are concerned, however, this factor may not be important.

We thank the Wellcome Trust and Smith and Nephew, Ltd., for fellowships for S. H. F. and the MRC for a

grant. We also thank Mr R. Ginn and Mr R. Flower for technical assistance.

# Haemoglobin Synthesis in $\alpha$ -Thalassaemia (Haemoglobin H Disease)

by

J. B. CLEGG

D. J. WEATHERALL

Nuffield Unit of Medical Genetics,  
Department of Medicine,  
University of Liverpool

In haemoglobin H disease, the rate of synthesis of the  $\alpha$ -chains of haemoglobin is depressed, while that of the  $\beta$ -chains remains normal. It is shown that part of this excess of  $\beta$ -chains forms a pool capable of further participation in haemoglobin synthesis. The  $\beta$ -chains of haemoglobin H can exchange reversibly with those of haemoglobin A in the intact red cell.

THE thalassaemias are a group of inherited anaemias resulting from a reduced rate of synthesis of the peptide chains of haemoglobin. Normal adult haemoglobin A has two  $\alpha$ - and two  $\beta$ -peptide chains which are under independent genetic control. There are therefore two principal groups of thalassaemias, one resulting from defective  $\alpha$ -chain synthesis, called  $\alpha$ -thalassaemia, and the other resulting from defective  $\beta$ -chain synthesis,  $\beta$ -thalassaemia<sup>1</sup>.

In  $\beta$ -thalassaemia the reduced rate of  $\beta$ -chain synthesis can be compensated in part by increased production of the other normal haemoglobin components, haemoglobin F, which has two  $\alpha$ -chains and two  $\gamma$ -chains, and haemoglobin A<sub>2</sub>, which has two  $\alpha$ -chains and two  $\delta$ -chains. Because the  $\alpha$ -chains of haemoglobins A, F and A<sub>2</sub> are controlled by a single genetic locus, however, synthesis of all these haemoglobins is depressed in  $\alpha$ -thalassaemia. In this disorder, haemoglobin H ( $\beta_4$ ) and Bart's ( $\gamma_4$ ) are found in varying amounts. It has been suggested that these abnormal haemoglobins arise by aggregation of excess  $\beta$ - and  $\gamma$ -chains which are present in the cell because of the overall deficit in  $\alpha$ -chains<sup>1</sup>.

The homozygous state for  $\alpha$ -thalassaemia is characterized by intra-uterine death with the clinical picture of hydrops foetalis associated with very high proportions of haemoglobin Bart's and very little haemoglobin A or F (ref. 2). The heterozygous state is very difficult to recognize in adult life and is unassociated with anaemia or a raised reticulocyte count, suggesting that one normal  $\alpha$ -chain gene is able to compensate almost completely for lack of  $\alpha$ -chain production by the abnormal allele.

Haemoglobin H disease is a form of  $\alpha$ -thalassaemia of intermediate severity, characterized by the presence of 5–25 per cent haemoglobin H, and a moderately severe haemolytic anaemia. It is currently believed that this condition results from heterozygosity for 2 different  $\alpha$ -thalassaemia genes, the severe type which results in hydrops foetalis in homozygotes (the  $\alpha_1$ -thalassaemia gene), and a "milder" gene (the  $\alpha_2$ -thalassaemia gene) (ref. 3). Because of the associated anaemia and reticulocytosis, blood samples from patients with haemoglobin H disease can be used to study *in vitro* haemoglobin synthesis in  $\alpha$ -thalassaemia. Studies of the haemoglobin patterns of stillborn infants apparently homozygous for the  $\alpha_1$ -thalassaemia gene suggest that it is completely ineffective in directing  $\alpha$ -chain production<sup>4</sup>. Thus the  $\alpha$ -chain synthesized in haemoglobin H disease will be almost entirely due to the activity of the milder  $\alpha_2$ -thalassaemia gene.

Previously, it was shown that in haemoglobin H disease the rate of  $\beta$ -chain synthesis exceeded that of  $\alpha$ -chain synthesis by a factor of 1.5 to 3 times (ref. 5). It was suggested that the excess of  $\beta$ -chain produced a large intracellular pool capable of contributing  $\beta$ -chains to

newly synthesized haemoglobin A. The present study confirms this suggestion and provides a more complete picture of the kinetics of  $\alpha$ - and  $\beta$ -chain production in haemoglobin H disease.

Approximately 5 ml. of red cells, obtained from patients with haemoglobin H disease, were washed in saline and incubated at 37° C under the conditions described by Lingrel and Borsook<sup>6</sup>. After incubation for 15–30 min, 50–250  $\mu$ c. of tritiated leucine was added and the incubation allowed to continue for periods of time ranging between 10 and 60 min. The cells were then washed and lysed, and the lysate divided into two parts. Globin was prepared from one fraction, without any further purification, by precipitation with cold 2 per cent acid-acetone. This "globin" thus consisted of material both from the soluble haemoglobin fraction, and from any haemoglobin bound to insoluble stromal matter together with the insoluble cell debris. The second fraction was centrifuged at 4° C to remove the stroma, and then either dialysed for 12 h at 4° C against the phosphate buffer to be used in a subsequent chromatographic separation of haemoglobins A and H, or immediately passed through a 'Sephadex G-25' column, equilibrated against the same buffer. The haemoglobins were then separated on 'Amberlite IRC-50' columns using developer No. 2 of Allen *et al.*<sup>7</sup>. Under these conditions, haemoglobins H and Bart's appeared in the "breakthrough" peak at 4° C. The haemoglobin A fraction, which was retained by the column at 4° C, was later eluted at 24° C after all the haemoglobin H and Bart's had been eluted. The two fractions were then concentrated at 4° C by pressure dialysis, and converted into globin by the acid-acetone method. The  $\alpha$ - and  $\beta$ -chains were isolated on CM cellulose columns in 8 molar urea/2-mercaptoethanol buffers as previously described<sup>8</sup>. The purified chains were freed of urea and salts and the incorporated radioactivity then determined. The relative amounts of haemoglobins A, Bart's and H were estimated by starch block or cellulose acetate electrophoresis, or by chromatography on 'Amberlite IRC-50'.

Radioactive  $\alpha$ - and  $\beta$ -chains were isolated from unfractionated whole cell lysates made from cells of non-thalassaemic patients with a variety of haemolytic anaemias. In all cases the amount of radioactivity incorporated into the  $\alpha$ - and  $\beta$ -chains was closely similar, as were the specific activities of the chains, suggesting that  $\alpha$ - and  $\beta$ -chains are produced at the same rate in non-thalassaemic reticulocytes. In similar experiments, using cells from individuals with haemoglobin H disease, however, the amount of radioactivity incorporated into the total  $\beta$ -chain fraction (that is, the  $\beta$ -chain of HbA and HbH) exceeded that found in the  $\alpha$ -chain, by ratios ranging from 2.7/1 to 1.9/1 (Fig. 1a, Table 1). The red

Table 1. RADIOACTIVITY OF THE  $\alpha$ - AND  $\beta$ -CHAINS ISOLATED FROM UNFRACTIONATED WHOLE CELL LYSATES PREPARED FROM THE CELLS OF PATIENTS WITH HAEMOGLOBIN H DISEASE AND PATIENTS WITH A RAISED RETICULOCYTE COUNT ASSOCIATED WITH NON-THALASSAEMIC DISORDERS

Diagnosis	Incubation time (min)	Total radio-activity in $\alpha$ -chain (c.p.m.)	Total radio-activity in $\beta$ -chain (c.p.m.)	Ratio $\alpha/\beta$
Haemoglobin H	10	4,180	7,972	0.5/1
Haemoglobin H	60	4,720	11,150	0.4/1
Haemoglobin H	60	8,070	22,560	0.3/1
Haemoglobin H	6	130	340	0.4/1
Immune haemolytic anaemia	10	2,059	2,085	1/1
Post-haemorrhagic anaemia	60	3,050	3,075	1/1

cells in haemoglobin H disease are hypochromic and have a marked reduction in mean corpuscular haemoglobin concentration. These findings therefore provide clear evidence that the rate of  $\alpha$ -chain synthesis is reduced in this condition, and do not support the hypothesis that haemoglobin H disease is due primarily to an overproduction of  $\beta$ -chain in the presence of normal levels of  $\alpha$ -chain synthesis. In addition to an excess of radioactivity in the  $\beta$ -chain fraction relative to that in the  $\alpha$ -chain, there is also an excess of protein as measured by the optical density at 280 m $\mu$ . This represents the  $\beta$ -chain of haemoglobin H (Hb  $\beta_4$ ), which appears with the  $\beta$ -chain peak on chromatography of globin made from the crude whole cell lysates. The excess of protein in the  $\beta$ -chain peak was proportional to the level of haemoglobin H in each case.

The presence of such an obvious excess of  $\beta$ -chain in the haemoglobin H disease cells raised the question of its role

in the overall pattern of haemoglobin synthesis, and, indeed, of its exact nature, for it was conceivable that some or all of the haemoglobin H seen in cell lysates forms by aggregation of  $\beta$  subunits on cell lysis. It is possible that it exists in a large labile pool of free  $\beta$ -chain monomer, capable of supplying  $\beta$ -chains to combine with newly synthesized  $\alpha$ -chains, as these become available to form haemoglobin A. If this were the case, however, virtually no labelled  $\beta$ -chain would be expected to appear in haemoglobin A during these experiments, for the relatively small number of  $\beta$ -chains synthesized would be greatly diluted by such a vast intracellular pool of unlabelled  $\beta$ -chain.

Table 2. RADIOACTIVITY OF THE  $\alpha$ - AND  $\beta$ -CHAINS PREPARED FROM PURIFIED HAEMOGLOBIN A FROM LYSATES OF THE RED CELLS OF FIVE PATIENTS WITH HAEMOGLOBIN H DISEASE AND A PATIENT WITH A RAISED RETICULOCYTE COUNT DUE TO A NON-THALASSAEMIC DISORDER

Diagnosis	Incubation time (min)	Specific activity of $\alpha$ -chain (c.p.m./mg)	Specific activity of $\beta$ -chain (c.p.m./mg)	Ratio $\alpha/\beta$
Haemoglobin H	10	378	218	1.7/1
Haemoglobin H	10	266	57	4.6/1
Haemoglobin H	60	375	47	7.9/1
Haemoglobin H	60	507	54	9.3/1
Haemoglobin H	300	603	191	3.1/1
Immune haemolytic anaemia*	60	630	658	0.95

\* The  $\alpha/\beta$  ratio is almost unity as previously reported<sup>3</sup>.

To clarify these points, haemoglobin A was separated from haemoglobin H, the  $\alpha$ - and  $\beta$ -chains isolated and the incorporated radioactivity determined (Fig. 1*b*; Table 2). In each case, the specific activity of the  $\alpha$ -chain exceeded that of the  $\beta$ -chain, the ratio of  $\alpha/\beta$  ranging from 9.3/1 to 1.7/1. The distribution of radioactivity, in the completed haemoglobin A, could only have occurred if the excess of  $\beta$ -chains released into the red cells had formed a pool capable of providing  $\beta$ -chains to combine with newly made  $\alpha$ -chains. Thus, during the period of incubation with tritiated leucine, newly made and therefore labelled  $\alpha$ -chain would combine with unlabelled  $\beta$ -chain from this pool. As seen in Fig. 1*b* and Table 2, however, there was always a considerable amount of radioactivity associated with the  $\beta$ -chain peak of the purified haemoglobin H, suggesting that if a usable pool of free  $\beta$ -chain is present it must be quite small. Alternatively, it was possible that the radioactivity in the  $\beta$ -chain of haemoglobin A was derived from haemoglobin H by some unspecific process of exchange of  $\beta$ -chain subunits. Such exchange might occur after lysis of the cells before complete chromatographic separation of haemoglobin A and haemoglobin H had been achieved, or intracellularly during the period of incubation.

To test the first hypothesis, cells from a patient with haemoglobin H disease were incubated for 45 min with tritiated leucine, lysed in cold water, and the stroma removed by centrifugation at 4° C. The lysate was then divided into two parts. One fraction was immediately passed through a 'Sephadex G-25' column equilibrated with developer No. 2, pH 7.18, which was also used to equilibrate an 'Amberlite IRC-50' column, both columns being maintained at 4° C. Immediately after passage through 'Sephadex', the lysate was applied to the 'Amberlite' column and haemoglobin H immediately eluted at 4° C. Haemoglobin A was then subsequently eluted at 24° C. Complete separation of haemoglobins A and H was completed within 1 h. The second fraction was dialysed against the same phosphate buffer for 48 h at 4° C, before application to the 'Amberlite' column, and the haemoglobins A and H were then separated as before. The  $\alpha$ - and  $\beta$ -chains from the purified haemoglobin A from each fraction were separated and their specific activities determined. The specific activity of the  $\beta$ -chain of haemoglobin A prepared from the sample dialysed for 48 h was 57 c.p.m./mg, while that of the sample which was separated immediately was 58 c.p.m./mg (Table 3). Thus no significant exchange of  $\beta$ -chain subunits between haemoglobin H and A occurs on prolonged dialysis under these conditions, and therefore this mechanism cannot account for most of the radioactivity found in the  $\beta$ -chain of haemoglobin A in our

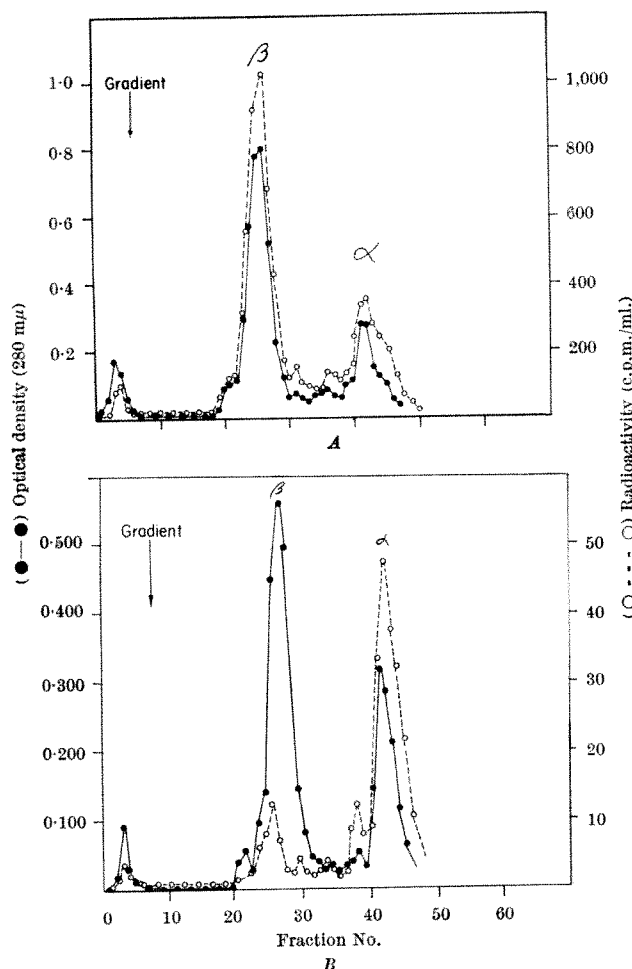

Fig. 1. A, Distribution of radioactivity in the  $\alpha$ - and  $\beta$ -chains of a lysate prepared from the red cells of a patient with haemoglobin H disease, after 60 min incubation with tritiated leucine. Globin was precipitated after lysis of the cells without further purification. B, Distribution of radioactivity in the  $\alpha$ - and  $\beta$ -chains of purified haemoglobin A prepared from the red cells of a patient with haemoglobin H disease, after 60 min incubation with tritiated leucine.

experiments. Furthermore, the period of dialysis was about four times greater than that usually used in these experiments.

Table 3. INVESTIGATION OF THE POSSIBILITY OF EXCHANGE OF SUBUNITS BETWEEN HAEMOGLOBINS A AND H AFTER LYSIS OF THE RED CELLS

Procedure	Specific activity of $\alpha$ -chain (c.p.m./mg)	Specific activity of $\beta$ -chain (c.p.m./mg)	Proportion of haemoglobin H (per cent)
Haemoglobin H separated by immediate chromatography	266	58	20
Haemoglobin H separated after 48 h dialysis at 4° C	262	57	20

Two experiments were performed to test the possibility of intracellular exchange of  $\alpha$ -chain subunits between haemoglobins A and H. 2 ml. of red cells from a patient with haemoglobin H disease were incubated for 1 h with tritiated leucine and further protein synthesis then stopped by the addition of puromycin to a final concentration of mmole. After incubation for 10 min with puromycin a sample was removed and the cells were washed in the cold and then frozen. Incubation of the remaining cells in the presence of puromycin was allowed to continue for a further 6 h, and the cells were then washed and frozen. Next, both lysates were thawed, centrifuged in the cold to remove the stroma, and haemoglobins A and H quickly purified by passage through 'Sephadex' and 'Amberlite' columns at 4° C as before. The  $\alpha$ - and  $\beta$ -chains of haemoglobin A and the  $\beta$ -chains of haemoglobin H were isolated by CM-cellulose chromatography and the specific activity of each determined (Table 4). The specific activity of the  $\beta$ -chain of haemoglobin A had increased by more than 50 per cent after 6 h, an equivalent loss of radioactivity in the  $\beta$ -chain of haemoglobin H being noted. In a second experiment (Table 4), synthesis was stopped by puromycin after incubation for 1 h with isotope, and samples were removed and frozen at intervals up to 20 h. There was a steady increase in radioactivity in the  $\beta$ -chain, the specific activity having more than doubled after 20 h. A reciprocal fall in radioactivity in the  $\beta$ -chain of haemoglobin H was again noted.

Table 4. INTRACELLULAR EXCHANGE OF  $\beta$ -CHAINS BETWEEN HAEMOGLOBIN H AND HAEMOGLOBIN A

Hours of incubation after inhibition with puromycin	Specific activities of peptide chains of haemoglobin A (c.p.m./mg)	$\beta$	Specific activity of $\beta$ -chain of haemoglobin H (c.p.m./mg)	Proportion of haemoglobin H (per cent)
Experiment 1				
0	507	54	1,600	21
7	485	83	1,545	22
Experiment 2				
0	312	36	1,160	23
6	324	58	1,090	22
20	312	78	1,050	22

The results of these experiments provide clear evidence that intracellular exchange of subunits does occur. The amount of this exchange is, however, insufficient to explain the degree of labelling of the  $\beta$ -chain which occurs during incubation for 60 min of red cells from persons with haemoglobin H disease. Thus about 10 per cent of the radioactivity present in the  $\beta$ -chain of haemoglobin A after incubation for 60 min probably arises by intracellular subunit exchange during the incubation. Unless some very unusual exchange process takes place immediately on lysis, the remaining 90 per cent of the counts must represent genuine *de novo*  $\beta$ -chain incorporation during the synthesis of the haemoglobin A.

As far as we are aware, these experiments demonstrate for the first time that subunit exchange between haemoglobins can occur intracellularly. Extracellular exchange of haem has been recently reported, but exchange of globin

subunits was not demonstrated<sup>9</sup>. Apparently extracellular exchange of globin subunits does occur, however, under rather extreme conditions<sup>10</sup>.

From these experiments, a fairly clear picture of the kinetics of  $\alpha$ - and  $\beta$ -chain synthesis in haemoglobin H disease can be built up. There is a reduced rate of synthesis of  $\alpha$ -chains resulting in an excess of  $\beta$ -chains, which are freely released into the red cell. Most of these chains probably form tetramers (haemoglobin H), and in that state are no longer available for combination with newly made  $\alpha$ -chain to form haemoglobin A. This concept is in keeping with the fact that the  $\beta$ -chains of haemoglobin A contain considerable amounts of radioactivity which cannot be accounted for by exchange of subunits between haemoglobins H and A, either within the cells or after lysis of the cells. These observations provide very strong evidence for the existence of a relatively small pool of free  $\beta$ -chain in haemoglobin H disease. Whether this exists as  $\beta$ -chain monomer or  $\beta_2$  dimer is uncertain, but because haemoglobin probably passes through the  $\alpha\beta$  subunit during synthesis, and because  $\beta_4$  subunits would probably tend to form rapidly the  $\beta_4$  tetramer, the usable pool may well be principally in the monomeric state. The situation may be compared with that found in normal reticulocytes, where a small pool of  $\alpha$ -chain, probably on the ribosomes, is responsible for the unequal labelling of  $\alpha$ - and  $\beta$ -chains at very short times of incubation<sup>5,11</sup>.

These experiments also confirm the destruction and loss of haemoglobin H from the circulating red cells. Thus the specific activity of the total  $\beta$ -chain fraction is always significantly greater (by a factor of 10–20 per cent) than that of the  $\alpha$ -chain of haemoglobin A, confirming that  $\beta$ -chain is not present in the red cell population at the same level as it is being synthesized. This is probably a reflexion of the fact that a heterogeneous population of cells is being studied, with the cells active in synthesis producing haemoglobin H at a rate greater than that which is compatible with the level of haemoglobin H in the total cell population. This discrepancy is due to the fact that haemoglobin H tends to precipitate as the red cell matures, aged red cells containing the resulting inclusion bodies being removed by the spleen<sup>12</sup>. The removal of cells containing precipitated haemoglobin H by the spleen has been previously suggested by *in vivo* labelling of haemoglobin<sup>13</sup>.

These experiments unfortunately provide no insight into the nature of the defect in  $\alpha$ -chain synthesis, but they do at least suggest that the next obvious step is to examine in detail the assembly of the  $\alpha$ -chain at the ribosomal level. What meagre genetic evidence there is points to a locus very close to, or at, the  $\alpha$ -chain locus, suggesting that a functionally defective mRNA may be involved. Alternative mechanisms involving regulatory genes affecting the production of mRNA, while no less plausible, would not at present prove as amenable to experiment in human material.

# Pattern Recognition in Bees

by

RUDIGER WEHNER

Zoological Institute,  
University of Frankfurt a.M.

Experiments show that there is a mechanism which enables bees to measure different angles of stripes on a vertical screen, and what kinds of stimuli may be decisive as sensory input.

THE way in which animals recognize shapes can be studied by their reactions to simple geometrical figures. We have carried out experiments to identify the specific parameters which are necessary for the visual system of animals to analyse figures. Even as simple a geometrical configuration as a black stripe can be described by many parameters, such as its size, the contrast between the stripe and the background, its outlines—which may be sharp or diffuse—or the orientation of the stripe on a vertical screen. With regard to the sensory input of form perception, these parameters need not be of equal importance. In the classical papers on form perception in bees<sup>1-9</sup> the total amount of black and white contours was considered the most decisive criterion enabling insects to discriminate between different geometrical figures. Some recent findings on arthropods taken from the ethological as well as from the electrophysiological point of view, however, show a more complex system of form perception.

The existence of retinal receptive fields has been proved for arthropods as well as vertebrates. One of the most common properties of these receptive fields is a specific angular size or the subdivision into excitatory

Fig. 1. Schematic representation of the apparatus. In the critical tests two angles of a stripe pattern (here single stripes) are presented on a vertical screen. The bees were formerly trained to a horizontal stripe ( $\alpha_+ = 0^\circ$ ). A shows the arrangement of stripes in the critical tests in order to determine the accuracy of goniometry. Size of  $\alpha_+$  could be varied from  $0^\circ$  to  $90^\circ$ . B shows the arrangement in the transfer tests (for further explanation see text). The position of patterns  $\alpha_+$  and  $\alpha_v$  on the screen was changed periodically.

Fig. 2. The discrimination of differently sloped stripe patterns from the patterns in the horizontal position ( $\alpha_+ = 0^\circ$ ).  $\alpha_+$  = training pattern. The angle of the control pattern,  $\alpha_v$ , varied from  $0^\circ$  to  $50^\circ$ .  $R$  = reaction intensity, that is, percentage of visiting flights to  $\alpha_+$ . The symbols represent the mean values of the single tests carried out with  $30 \pm 5$  bees. The curves always join the total average of all tests.

and inhibitory areas. One type of receptive field, however, is strikingly characterized by sensitivity to the specific direction of a light slit, a dark stripe or a moving point of light. These directionally selective units, previously found in vertebrates, crustaceans and insects, only respond to a certain direction of visual stimuli in the inherent receptive field. In the past few years, electrophysiological recordings have been made from these units in the tectum opticum of frog<sup>10</sup> and pigeon<sup>11</sup>, the lateral geniculate body<sup>12</sup> and the retina<sup>13-16</sup> of the rabbit, the visual cortex of the cat<sup>17-20</sup>, the eyestalks of the crab *Podophthalmus*<sup>21</sup>, the optic nerve of the crayfish<sup>22-24</sup> and the medulla externa of the locust<sup>25</sup>. Also there is evidence that the directionally selective units occur in the octopus<sup>26,27</sup>.

The experiments reported here were designed to find out whether bees are able to measure the slope of black stripes presented on a vertical screen, how precisely such a mechanism of goniometry works and what kind of stimuli are necessary as sensory input. The apparatus consisted of a vertical plane ( $165 \times 100$  cm) to which three types of stripe patterns were applied: single stripes; sets of parallel black and white stripes equidistant apart;

and a cross-like configuration of two stripes. In all three types, the orientation of the stripes varied from the horizontal ( $\alpha = 0^\circ$ ) to the vertical ( $\alpha = 90^\circ$ ). During each experiment a group of about 30 ( $\pm 5$ ) individually marked bees was trained to a certain slope of the stripes called the "positive" angle  $\alpha_+$ . The bees had to crawl through an aperture 10 mm in diameter in the centre of the stripe and then enter a dark box in which they found a solution of saccharose (0.2–2 molar). The training to  $\alpha_+$  lasted for at least 10 h so that the bees would make 100–150 approach flights to the  $\alpha_+$  pattern. (For further details see ref. 28.)

Once the bees had been trained to a certain slope,  $\alpha_+$ , of the stripes, a series of critical tests was carried out. In all these tests the bees had to discriminate between two directions of the same pattern: the positive angle  $\alpha_+$  remained constant during all tests, while the other pattern orientated at  $\alpha_v$  was varied throughout the whole range from  $0^\circ$  to  $90^\circ$  ( $0^\circ \leq \alpha_v \leq 90^\circ$ ) (Fig. 1A). The percentage of bees that chose  $\alpha_+$  was noted in each test. The results for  $\alpha_+ = 0^\circ$ , that is for a horizontally arranged stripe or stripe pattern, are given in Fig. 2. The curves rise steeply as the difference between the constant training pattern,  $\alpha_+$ , and the varying control pattern,  $\alpha_v$ , increases, and finally they reach a plateau. The so-called "similarity range"  $\Delta\alpha_0$  encloses by definition all directions  $\alpha_v$  which are not optimally distinguished by the bees from the training angle  $\alpha_+$ . It represents therefore the ascending part of the curves. Using the parameter  $\Delta\alpha_0$  one concludes from Fig. 2 ( $\alpha_+ = 0^\circ$ ) and Fig. 3 ( $\alpha_+ = 45^\circ$ ) that there is no statistically significant difference between the values for a single stripe or a pattern of parallel stripes and that the cross-like patterns enable bees to measure angles more accurately ( $\Delta\alpha_0 = 20^\circ$ ) than do single or parallel stripes ( $\Delta\alpha_0 = 30^\circ$ – $40^\circ$ ).

In a special series of experiments<sup>28</sup>, it was found that bees managed to discriminate between the trained upright cross  $\alpha_+$  and an oblique cross  $\alpha_v$  at a difference of inclination of only  $4^\circ$  when they were simultaneously presented. A single stripe or a set of parallel stripes must be rotated

by  $10^\circ$  before it can be distinguished significantly from the horizontal one.

Bees were not only trained to horizontal stripes as described so far, but also to  $45^\circ$  and  $90^\circ$  inclination of the same stripe patterns. For  $\alpha_+ = 90^\circ$ , that is to say, after training to the vertically orientated stripes, there results a similar but mirror shape, for the curves compared with those obtained for  $\alpha_+ = 0^\circ$ . For  $\alpha_+ = 45^\circ$ , however, symmetrical curves as shown in Fig. 3 are typical. This means that it does not matter whether the control pattern  $\alpha_v$  presented in the tests simultaneously with the training pattern  $\alpha_+$  is inclined upward or downward from  $\alpha_+ = 45^\circ$ . This is in agreement with the previous finding that bees do not show an innate preference for horizontal or vertical stripes.

In order to decide whether bees can tell the slope of a stripe pattern more accurately from the training slope  $\alpha_+ = 0^\circ$  (or  $90^\circ$ ) than from  $\alpha_+ = 45^\circ$ , the following method can be used: the difference in angle between  $\alpha_+$  and  $\alpha_v$  at 60 per cent visiting flights to  $\alpha_+$  is read off the curves such as shown in Figs. 2 and 3. It can be seen that adjacent inclinations of stripes are more precisely discriminated within the range from  $0^\circ$  to  $90^\circ$  than in that about  $45^\circ$ . This is true for all types of stripe patterns used in the experiments (see Table 1).

The mechanism which enables bees to discriminate between two different slopes of the same stripe pattern can also be examined by another method. In critical tests two patterns are offered, neither of which is inclined at the training angle, Fig. 1B, one of them ( $\alpha_c$ ) remains constant throughout all tests whereas the other varies within the range of  $0^\circ \leq \alpha_v \leq 90^\circ$ . The curve in Fig. 4 is drawn from the results of a series of similar experiments, in which the bees were trained to a horizontal stripe ( $\alpha_+ = 0^\circ$ ) but when the same stripe was presented at an angle of  $45^\circ$  or  $90^\circ$ , the bees mostly refused to approach. When  $\alpha_v$  simultaneously offered with  $\alpha_c$  was greater than  $40^\circ$  most of the bees accepted neither, but returned to the hive. Bees only approached stripes which differed

Fig. 3. The discrimination of differently sloped stripe patterns from the patterns in the oblique position ( $\alpha_+ = 45^\circ$ ). For explanation see Fig. 2. The mean values of all tests are graphed. The true values for the single tests maximally scatter in the range of 20 per cent (in the case of  $\alpha_v = 30^\circ$  and  $60^\circ$ ).

Fig. 4. Transfer of the bees trained to horizontal stripes to other inclinations of single stripes. In the critical tests all angles were simultaneously presented with the constant control pattern  $\alpha_c = 90^\circ$  (●) or  $\alpha_c = 45^\circ$  (○). In the range  $\alpha_c > 50^\circ$  the bees scarcely visited either angle of the two stripes, and the few approach flights were distributed at random to both angles. In the (●) curve the mean values of the single tests are given, while the (○) curve only shows the total average values of all tests.

no more than  $30^\circ$ – $40^\circ$  from the training pattern  $\alpha_+ = 0^\circ$ . This means that the more horizontal of two stripes is exclusively preferred in the so-called "transfer range",  $\Delta\alpha_T = 30^\circ$ – $40^\circ$ , and thus the transfer range is identical with the "similarity-range" already described; in short,  $\Delta\alpha_T = \Delta\alpha_0$ . We may therefore conclude that only those stripes which are close to the training angle, and which are not optimally discriminated from the training angle, that is within  $30^\circ$ – $40^\circ$ , are acceptable to the bees. The same results are inferred from experiments with  $\alpha_+ = 45^\circ$  and  $90^\circ$ .

In another series of tests, the slope  $\alpha_c$ , which remains constant in all tests, was kept within the variation range:  $\alpha_c = 20^\circ$  and  $30^\circ$ , see Fig. 5. Now the bees already trained to the horizontal sets of parallel stripes ( $\alpha_+ = 0^\circ$ ) also accepted the control pattern  $\alpha_c$ . They always preferred the more horizontal of the two inclinations even when the angles differed by only  $10^\circ$ .

In all the experiments so far described the bees had to fly to a vertical screen. This means that the patterns offered on the screen were projected to the frontal part of the eye. The slope of the screen was now varied from the vertical position ( $\psi = 90^\circ$ ) to the horizontal one ( $\psi = 0^\circ$ ). In each position the bees had to discriminate between two stripe patterns: one at an angle of  $45^\circ$  ( $\alpha_+$ ), the other at an angle of  $135^\circ$  ( $\alpha_v$ ) to the horizontal direction. The longer the bees were trained the better they could distinguish between the two stripe patterns  $\alpha_+$  and  $\alpha_v$ . The "learning-curves" obtained show the percentage of approach flights to  $\alpha_+$  as a function of the number of training flights. The rate of rise and the plateau of these curves decrease

Table 1. THE DIFFERENCES IN THE ACCURACY OF GONIOMETRY FOR SINGLE STRIPES (SS), SETS OF PARALLEL BLACK AND WHITE STRIPES (PS) AND RECTANGULARLY CROSSED STRIPES (CS), EXAMINED FOR DIFFERENT TRAINING INCLINATIONS OF THE STRIPES ( $\alpha_+ = 0^\circ, 45^\circ, 90^\circ$ )

	$0^\circ$	$45^\circ$	$90^\circ$
SS	7.1	10.7 12.8 12.0 12.5	6.0
PS	7.8	10.6 11.8	6.6
CS	3.6 2.8	8.5 8.0	(See $0^\circ$ )

The values represent the angle difference between  $\alpha_+$  and the  $\alpha_c$  inclination which is distinguished from  $\alpha_+$  by 60 per cent of the trained bees. The curves which the considered values are read off are based on 28,617 approach flights of the trained bees. Each value graphed in the table is taken from one specific curve.

when the pattern plane is gradually brought from the vertical to the horizontal position as shown in Fig. 6. The mean values for  $\psi = 45^\circ$ – $90^\circ$  are significantly different from those for  $\psi = 0^\circ$ – $10^\circ$ .

The following conclusions are drawn from further experiments<sup>22</sup>: the pattern plane can be inclined out of the vertical position for a wider range than out of the horizontal position for the discrimination between the

Fig. 5. Transfer of the bees trained to the horizontal pattern to other angles of an equidistant stripe pattern. The testing situation is the same as that in Fig. 4, but the constant control pattern is now orientated at an angle  $\alpha_c = 20^\circ$  (○) and  $\alpha_c = 30^\circ$  (●). The mean values of all tests carried out represent the percentage of approach flights to  $\alpha_c = 20^\circ$  and  $30^\circ$  respectively.

two stripe patterns to be preserved. Measurement of the direction of stripes by the bees is more accurate if the stripe patterns are presented in the vertical than in the horizontal plane.

Offhand, it would seem possible that bees measure the slope of a black stripe on a vertical screen by means of terrestrial or celestial orientation marks in the surroundings of the plane to which the patterns are applied. To test this the bees were trained to a  $45^\circ$  stripe which ran from left-below to right-above or—with regard to the celestial regions—from east-below to west-above. During the experiment, the screen was rotated through  $180^\circ$  so that the pattern plane now looked south instead of north, its former orientation. Two stripes were presented in the test: one at an angle of  $45^\circ$ , the other at an angle of  $135^\circ$ . In the new position of the screen only a few bees chose one of the two stripes offered, but they all flew to the  $45^\circ$ -inclined stripe which now ran from west-below to east-above. This means that bees measure the angle of a stripe presented on a vertical screen by means of its orientation in the visual field, not by its position in space. This, however, does not apply to stripes offered in the horizontal plane<sup>29</sup>.

Another question is what parameter of sensory input is decisive in measuring the angle of a stripe. The total amount of black and white contours irrespective of their direction, cannot be the parameter necessary for goniometry; for a  $45^\circ$  and a  $135^\circ$  inclined stripe pattern are unequivocally distinguished, although both patterns have identical amounts of contour. The orientation of the contours is also not as important as may be supposed at first. The stripe contours can be dissected in a sawtooth like pattern without affecting the orientation of bees to the inclination of the long axis of the black stripe. The bees discriminate between the cross-shaped patterns in the upright and in the oblique position even when all the contours extend in a direction of  $45^\circ$  to the stripe axes (Fig. 7). It is only necessary then that the axes of the stripes and therefore the main extent of the black area coincide with the positive inclination to which the bees have been trained.

The results reported here prove the existence of a mechanism which enables bees to measure the different angles of a stripe or a stripe pattern presented on a vertical

Fig. 7. The patterns offered in order to decide whether edges or areas are decisive for goniometry. The bees were trained to an oblique cross A. In the critical tests the patterns  $B_1$  and  $B_2$  were presented. In all the tests in which the number as well as the size of the squares differed, 81–92 per cent of the trained bees chose the pattern of type  $B_1$  ( $n=2,135$ ).

screen. Similar training experiments have been carried out on cephalopods<sup>26</sup>, fishes<sup>20</sup>, birds<sup>31</sup> and mammals<sup>32,33</sup>. The number of ants running spontaneously to a vertically striped pattern greatly decreases when the stripe pattern is declined by more than  $20^\circ$  from the vertical<sup>34</sup>.

When bees are trained to a certain inclination  $\alpha_+$  of a stripe or pattern consisting of parallel black and white stripes they optimally discriminate from  $\alpha_+$  all inclinations varying from  $\alpha_+$  by more than  $30^\circ$ – $40^\circ$ . For comparison Hubel and Wiesel<sup>20</sup> have found with electrophysiological technique in the cat that cortical neurones representing directionally selective units show maximal spike frequencies when a light slit projected on the retina differs by no more than  $30^\circ$  from the direction for which the unit is selective. Such a mechanism of goniometry requires that the eyes of flying bees are always kept in the same position by proprioceptive control of the position of head and

Fig. 6. The discrimination of two oppositely orientated stripe patterns ( $\alpha_+ = 45^\circ$  and  $\alpha_- = 135^\circ$ ) as a function of the number of training flights ( $F$ ) and the inclination  $\psi$  of the plane of the patterns. Upper ( $\circ$ ) curve:  $\psi = 45^\circ$  to  $90^\circ$ ; ( $\bullet$ ) curve:  $\psi = 20^\circ$  to  $30^\circ$ ; lower ( $\circ$ ) curve:  $\psi = 0^\circ$  to  $10^\circ$ . Each of the curves represents the average of 5–6 curves obtained in a series with  $15 \pm 3$  bees. These 5–6 curves scatter in the range graphed for each mean value.  $N_t$  = No. of approach flights in the critical tests,  $N_d$  = No. of training flights. From Wehner, R., *Z. Vergl. Physiol.* (Springer-Verlag, Berlin, 1967).

thorax. By this the training inclination of stripes is always projected in the same way to the ommatidia. Wiersma and Yamaguchi<sup>22-24</sup> recently found, however, in the eyestalks of the crayfish some "space constant fibres" detecting a certain direction of visual stimuli irrespective of the position of the eyes.

The most important parameter for measuring the angle of stripes is the orientation of the long axes of the black stripes, but not the direction of the black and white contours. Even the optokinetic reactions of *Carcinus* and *Locusta* refer not only to the contours of a rotated stripe pattern, as believed so far, but also to the black areas<sup>25,26</sup>. In addition, further experiments lead to the conception—although not yet fully examined—that the orientation of bees to the direction of a vertically presented stripe is independent of the size of the stripe<sup>27</sup> and of the contrast in brightness between the dark stripe and its light background.

I thank Professor M. Lindauer for introducing me to the work with bees and for useful advice and discussion during the course of this study. I also thank Dr W. Rathmayer for reading the manuscript. This research has been supported by the Deutsche Forschungsgemeinschaft.

Molecules of high electron affinity may be able to enhance radiobiological damage by increasing the effective diffusion radius of hydrated electrons produced by radiation. They do this by acting as electron carriers and electron transfer agents.

BECAUSE of ground state electron delocalization, conjugation between electron acceptor groups greatly enhances the electron affinity of organic compounds<sup>1,2</sup>. Attachment of electrons to such molecules frequently produces relatively long lived, radical anions, particularly in solutions of high pH. Correlations between these electrophilic structures and radiobiological sensitization<sup>3-5</sup> have led to the characterization of a new class of radiosensitizers. These include the conjugated compounds, benzo- and acetophenone, quinones, dicarbonyl compounds, diethyl oxalate, derivatives of maleic, fumaric, phthalic and pyruvic acids, and also indane trione. The hypothesis was based originally on the postulate that molecules of high electron affinity, acting as electron carriers and electron transfer agents, enhanced radiobiological damage by increasing the effective diffusion radius of hydrated electrons produced by the radiation. Although other related models may be constructed, the empirical relationship between electron-affinity and radiobiological sensitization is reasonably well established.

Several suggestions have been made independently that the relative efficiency of two scavengers competing

for electrons of thermal energy, including solvated electrons, may depend on differences in electron affinity rather than on differences in reaction rate constants. This has been discussed in terms of the chemistry of the model referred to here<sup>3-5</sup>; the radiation chemistry to aqueous solutions<sup>4,6-8</sup>, organic liquids<sup>9</sup> and gas phase mixtures<sup>10</sup>:

The initial fate of the electron is governed clearly by the relative magnitude of the two terms  $k_1[A]$  and  $k_2[B]$ . If  $A$  and  $B$  differ in electron affinity, however, anionic transfer may occur

In pulse radiolysis studies, Baxendale *et al.*<sup>11</sup> have measured the rate of electron transfer from unstable metal ions, for example  $\text{Cd}^+$ ,  $\text{Zn}^+$  and  $\text{Pb}^+$ , to stable oxidizing metal ions and, in some cases, have determined the relative potentials of the couples  $M^+/M^{2+}$ . Electron

transfer from the electron adduct of nitromethane to tetranitromethane has been reported<sup>6</sup>. Similar phenomena have been observed for arene radical-ions in alcohols<sup>7</sup>.

In stationary state radiolyses, this type of competition has been observed in aqueous mixtures<sup>7,8</sup> and also gas mixtures<sup>10</sup>.

In this report, we discuss experiments in which pulse radiolysis has been used to explore the radiation chemical behaviour of some compounds of high electron affinity. The following acceptors have been used: acetone, acetophenone, benzophenone, fluorenone, N-ethylmaleimide, dimethylfumarate, nitrous oxide and oxygen.

Solutions in either triply distilled water or highly purified ethanol were made alkaline with potassium hydroxide and sodium ethoxide respectively. Samples were irradiated with a 0.2  $\mu$ sec pulse of 1.8 MeV electrons from a linear accelerator, and the transient changes in optical density were recorded spectrophotometrically. Experimental details of the pulse radiolysis equipment have been published previously<sup>12</sup>.

Transient spectra from several deoxygenated, aqueous, alkaline solutions of acetophenone, benzophenone and acetone are shown in Fig. 1. In Fig. 1 (a), curve (i) is the transient spectrum observed 1  $\mu$ sec after the pulse, from 3.34 mM solution of acetophenone at about pH 13. Curve 1 (a) (ii) is the spectrum from a solution containing 166 mM acetone and 0.84 mM acetophenone.

The absorption maximum at 4400 Å is assigned to the electron adduct of acetophenone

while the peak at 3700 Å, characteristic of irradiated aqueous solutions of aromatic compounds, is, with little doubt, caused by the OH adduct, a substituted cyclohexadienyl radical. In the presence of a high concentration of acetone (curve (ii)), the latter peak is suppressed because the precursors, OH radicals, are scavenged by this solute, but the peak at 4400 Å is virtually unaffected. Both solutes react with  $e_{\text{aq}}^-$  with almost diffusion-controlled rate constants, and, because the concentration of

acetone greatly exceeds that of acetophenone, the former solute will scavenge all hydrated electrons. The maximum at 4400 Å in curve (ii) is due, we believe, to the electron transfer reaction

Fig. 1 (b) shows a set of similar data for acetone and benzophenone. The spectrum (curve 1 (b) (i)) is produced 1  $\mu$ sec after irradiation of 165  $\mu$ M benzophenone at about pH 13. The peak near 6100 Å is clearly produced by the ketyl radical anion previously observed by both flash photolysis<sup>13</sup> and pulse radiolysis<sup>14</sup>, and that at 3700 Å has been assigned to the OH adduct<sup>14</sup>. In the presence of 44 mM acetone, the latter peak is suppressed, while the ketyl radical anion is unaffected. In this system, too, the acetone concentration is sufficient to prevent any direct electron scavenging by benzophenone, and, because in pulse radiolysis the ketyl radical anion can be formed only by electron attachment or ionization of the neutral, ketyl radical<sup>14</sup>, we conclude that electron transfer is again responsible.

The data from an experiment combining the two systems in Figs. 1 (a) and 1 (b) are shown in Fig. 2. The oxygen free solution contained 6 per cent acetone, 3.4 mM acetophenone, 72  $\mu$ M benzophenone and 0.1 N potassium hydroxide. The spectrum (i) with a maximum at 4400 Å was produced during the pulse and is identical to that of the acetophenone ketyl anion shown in Fig. 1 (a). Within 50  $\mu$ sec after the pulse, however, this spectrum decays and is replaced by another spectrum with a maximum near 6100 Å identical to that of the benzophenone ketyl anion. The oscillogram inset illustrates the kinetic behaviour. The rise in the optical density at 6100 Å is exponential, and occurs over a similar time scale to the decay of the 4400 Å peak. The latter decay is complicated slightly by a small, longer lived component, due probably

Fig. 1. Electron transfer spectra. a, Transient spectra from 3.3 mM acetophenone in aqueous  $10^{-1}$  N potassium hydroxide. (i) No acetone; (ii) 0.17 M acetone. b, Transient spectra from 0.2 mM benzophenone in aqueous  $10^{-1}$  N potassium hydroxide. (i) No nitrous oxide; (ii) nitrous oxide saturated. d, Kinetics of electron transfer from  $\text{N}_2\text{O}^-$  to fluorenone in ethanol containing  $10^{-2}$  N sodium ethoxide.

Fig. 2. Transient spectra from an aqueous solution containing 0.82 M acetone, 3.34 mM acetophenone, 72  $\mu$ M benzophenone and  $10^{-1}$  potassium hydroxide (nitrogen saturated). Spectra taken 2  $\mu$ sec (○) and 50  $\mu$ sec (●) after the pulse. Inset, oscillogram: build-up, absorption at 6100 Å; decay, absorption at 4400 Å. Ordinate: absorption, 2.1 per cent per division; abscissa: time, 10  $\mu$ sec/division.

to a species produced by reaction between OH and acetone, with a maximum at lower wavelengths.

In this system, acetone must scavenge all hydrated electrons, and therefore the sequential formation of the two ketyl anions indicates the occurrence of a simple three-stage chain electron transfer process

Henglein and co-workers<sup>8</sup> have shown that, in neutral solution and in the presence of excess nitrous oxide, the formation of the electron adduct of nitromethane is prevented. At a high pH, however, nitrous oxide appeared to be ineffective in competing for solvated electrons. They suggested that the equilibrium

was involved in the phenomena.

At low pH, the equilibrium lies to the right, and  $\text{N}_2\text{OH}$  decomposes rapidly to nitrogen and OH. In alkaline solution,  $\text{N}_2\text{O}^-$  is stabilized and is sufficiently long lived to permit electron transfer to nitromethane.

Pulse radiolysis studies<sup>15</sup> have shown that at natural pH, where equilibrium in equation (8) lies far to the right, the lifetime of  $\text{N}_2\text{O}^-$  is of the order of  $10^{-9}$  sec.

In the stationary state radiolysis of aqueous alkaline solutions of isopropanol it was suggested<sup>16</sup> that nitrous oxide reacts with the isopropanol radical ion to produce an oxidizing radical (OH). This would be in keeping with the mechanism of electron transfer to nitrous oxide.

The data in Fig. 1(c) provide some support for the relative stability of  $\text{N}_2\text{O}^-$  in alkaline solution.

Curve 1(c) (i) shows the transient spectrum immediately after the pulse in an aqueous solution containing 44  $\mu$ M fluorenone at pH 13. The maximum at 4400 Å is similar to that in acetophenone solutions, and is assigned to the fluorenone radical anion ( $\text{F}^-$ ). When the solution is saturated with nitrous oxide, before irradiation, the absorption of  $\text{F}^-$  is still observed.

We believe this effect, similar to that observed with nitromethane<sup>8</sup>, is due to electron transfer from the stabilized radical anion,  $\text{N}_2\text{O}^-$ .

Similar phenomena are observed in ethanolic solutions containing sodium ethoxide. Absolute confirmation of this  $\text{N}_2\text{O}$  mechanism does, however, require the elimination of the possibility of an  $\text{F}^-$  type spectrum being produced by ionization of an OH-adduct or by electron transfer from  $\text{O}^-$ .

We have been informed by Dr Baxendale that electron transfer to oxygen has been observed. Pulse radiolysis of solutions of  $\text{Zn}^{++}$  produces, by reduction, the transient ion,  $\text{Zn}^+$ , which decays by second order kinetics. In the presence of small but excess amounts of oxygen, the absorption decays first order in oxygen<sup>11</sup>

We find that in the presence of oxygen, the radical anions of fluorenone, benzophenone and the other acceptors, produced by electron attachment or by chain electron transfer, decay by an exponential process. In all cases the half times are inversely proportional to oxygen concentration indicating that reaction (11) takes place.

We have found no evidence for peroxyanion-radical formation which would favour the mechanism of electron transfer rather than oxygen addition for reaction (11).

Fig. 1(d) shows that, in alkaline ethanolic solutions saturated with nitrous oxide, the first order rate constants for electron transfer to fluorenone are proportional to fluorenone concentration. From the slope, the second order rate constant was calculated and is given in Table 1.

Table 1

Donor	Acceptor	Solvent	Potassium hydroxide or sodium ethoxide (mM)	Rate constant ( $\text{M}^{-1} \text{sec}^{-1}$ )
Acetone-	Fluorenone	Ethanol	16	$2.0 \times 10^9$
Acetone-	Acetophenone	Water	100	$7.8 \times 10^8$
Acetophenone-	Benzophenone	Water	100	$7.8 \times 10^8$
$\text{N}_2\text{O}^-$	Benzophenone	Water	100	$1.3 \times 10^9$
$\text{N}_2\text{O}^-$	Fluorenone	Water	100	$1.2 \times 10^9$
$\text{N}_2\text{O}^-$	Fluorenone	Ethanol	100	$2.5 \times 10^9$
Fluorenone-	Oxygen	Ethanol	10	$8.9 \times 10^8$
Fluorenone-	Oxygen	Ethanol	10	$9.8 \times 10^8$
( $\text{N}_2\text{O}$ satd.)				
Dimethylfumarate-	Oxygen	Water	1	$5.3 \times 10^9$
Dimethylfumarate-	Oxygen	Ethanol	10	$1.5 \times 10^9$

Data for various electron transfer reactions are also given in Table 1 and were obtained from the slope of similar plots.

We wish to thank Professor J. J. Weiss and Dr G. Scholes, of the University of Newcastle, for their helpful interest.

# Electron Thermodynamic Nonequilibrium in $p$ - $n$ Junctions

by

M. A. MELEHY

Electrical Engineering Department and  
Materials Science Institute,  
University of Connecticut,  
Storrs, Connecticut

The concepts of the recently proposed "generalized field theory"—a theory which attempts to differentiate completely between active and passive transport processes—are applied to forward conduction in  $p$ - $n$  junctions. The predictions of the theory agree very closely with the results of experiments.

In some heterogeneous systems, thermodynamic equilibrium and nonequilibrium can be accounted for by a new phenomenological theory<sup>1,2</sup> which has the property of making a strict distinction between reversible (active) and irreversible (passive) transport processes. One consequence of this generalized field theory is that in equilibrium each irreversible transport process vanishes, and each reversible transport process is conservative. These conditions, which apply to each constituent in multi-component systems, are necessary and sufficient for equilibrium. Further consequences of this theory include new interpretations of the principle of detailed balancing, and the fundamental law of conservation of energy as applied to transport processes. What follows is a new theory of forward conduction in  $p$ - $n$  junctions based on the generalized field theory.

## The Generalized Field Theory

In order to state the hypotheses of the generalized field theory for the case of conduction electrons in solids, for example, two definitions are necessary. First, passive or irreversible processes are defined as those which involve flow and which invariably increase the internal energy of the host medium, usually as a result of positive entropy production. An obvious example is that of ohmic conduction in a resistor. A less obvious example is the diffusion which occurs only during conduction in the homogeneous  $n$  and  $p$  regions of a  $p$ - $n$  junction.

Active or reversible transport processes, by contrast, are defined as those which can exist in equilibrium. According to the direction of current flow, there may be an increase or a decrease of the internal energy of the host medium. One obvious example is that associated with the electromotive force of a battery. Less obvious examples are the electrostatic and diffusion processes in the interface regions between two solids—the transition region of a  $p$ - $n$  junction, for example.

It is now possible to state the three following hypotheses.

(1) Associated with every physical transport process involving conduction electrons in solids there exists a force per electron, statistical or otherwise. This force constitutes a vector field, which is mathematically defined throughout the solid, regardless of whether this process is reversible, irreversible, conservative or non-conservative.

(2) If conduction electrons are involved in any irreversible transport processes, which are varying sufficiently slowly in time, so that inductive and capacitive effects are negligible, then near equilibrium the electron current density  $\mathbf{J}_n$ , at any point  $Q$ , is related to the generalized irreversible force  $\mathbf{f}_i$  per electron, associated with all the processes at that point, by

$$\mathbf{J}_n = -\mu_n n \mathbf{f}_i \quad (1)$$

where  $n$  and  $\mu_n$  are the electron concentration and mobility at  $Q$ , respectively. For the reversible generalized force  $\mathbf{f}_r$ , however, the preceding relation will not hold.

(3) Around every possible closed loop,  $C$ , within any solid medium, under the conditions stated for the second hypothesis, the reversible and irreversible generalized forces per electron associated with all the processes are related by

$$\oint_C (\mathbf{f}_r - \mathbf{f}_i) \cdot d\mathbf{l} = 0 \quad (2)$$

where  $d\mathbf{l}$  is an increment of length along the closed loop.

Similar statements may be made for holes in semiconductors.

The thermodynamic field, to be designated by  $\mathbf{f}_t$ , is defined as the statistical force per electron associated with the gradient of the electron concentration  $n$  and of the temperature  $T$ . The mathematical existence of  $\mathbf{f}_t$  at every point in a system has been specified by the first hypothesis. Furthermore, it can be shown<sup>1</sup>, on the basis of the first and second law of thermodynamics, that

$$\mathbf{f}_t = \mathbf{f}_T + \mathbf{f}_d, \quad \mathbf{f}_T = s \nabla T, \quad \mathbf{f}_d = -(1/n) \nabla P \quad (3)$$

where  $\mathbf{f}_T$  is the virtual or effective thermal force per electron,  $\mathbf{f}_d$  is the diffusion force per electron,  $s$  is the absolute entropy per electron, and  $P$  is the electron internal pressure, which is strictly expressed by the equation of state<sup>3</sup>.

When the proposed hypotheses of nonequilibrium are interpreted from the point of view of a few fundamental laws of nature, one can deduce<sup>2,3</sup> the new generalized conditions of equilibrium stated earlier, and the new generalized principle of detailed balancing, which states: at any point in a thermodynamic system in equilibrium, for every particle of a specific constituent which is crossing a given area per unit time in one direction, under the action of each process, there is another particle of the same constituent crossing in the opposite direction. This is in contrast with the conventional interpretation of the balancing considered to be caused necessarily by all the processes combined.

It can be shown<sup>2,3</sup> that Ohm's Law and Fick's Law can be derived from the second hypothesis. Thus Ohm's law and Fick's law represent purely irreversible phenomena and, according to the generalized field theory, cannot be used to explain the completely reversible conditions of equilibrium, such as those prevailing in the transition region of a  $p$ - $n$  junction.

## Theory of Forward Conduction in $p$ - $n$ Junctions

In 1949 the first theory of conduction in  $p$ - $n$  junctions was presented by Shockley<sup>4</sup>. It was assumed then that there was no carrier recombination in the transition region, and that conduction was caused by the injection of

minority carriers, which would recombine and diffuse in the bulk regions. Using the conventional hypotheses of thermodynamic equilibrium and nonequilibrium, Shockley has shown<sup>4</sup> that the diode forward applied d.c. voltage  $V$  and current  $I$  are related by an equation equivalent to

$$V = V_T \ln(1 + \alpha'), \quad \alpha' = I/I_s \quad (4)$$

$$V_T = kT/q \quad (5)$$

where  $k$  is Boltzmann's constant,  $q$  is the magnitude of the electron charge and  $I_s$  is the reverse-saturation current.

Equation (4) has been found to be in agreement with experiment only at low injection levels in germanium diodes<sup>5</sup>. Since 1949 there has been more than seven different theories proposed<sup>6-9</sup> to explain quantitatively or qualitatively portions of the problem of forward conduction in germanium, silicon and gallium-arsenide  $p$ - $n$  junctions. Most theories have assumed processes leading to new current mechanisms, which make theory and experiment agree under strongly restricted conditions.

By contrast, analysing the conduction processes proposed by Shockley<sup>4</sup> in 1949, on the basis of the generalized field theory, seems to lead to results in agreement with most published experimental data on (non-tunnelling)  $p$ - $n$  junctions regardless of material, temperature and injection levels. Specifically, if one neglects the irreversible electrostatic process (ohmic conduction) and assumes that the injection is carried by one type of carrier, such as holes, then the forward voltage-current characteristics can be shown<sup>10</sup> to be given by

$$V = V_T \ln(1 + \alpha) + V_T[1 - (1/\alpha) \ln(1 + \alpha)] + \delta\psi \quad (6)$$

$$\alpha = (II), \quad p_e = (1 + \alpha)p_n \quad (7)$$

where  $I^*$  is defined as the reverse-saturation current, and  $p_e$  and  $p_n$  are the concentration of minority holes at the  $n$ -region boundary and sufficiently far from the junction, respectively.

The quantity  $\delta\psi$  represents the increase in the junction

reversible electrostatic voltage caused almost entirely by the deviation  $\delta p(y)$  of the distribution of hole concentration  $p_1(y)$  from its equilibrium value  $p_0(y)$ , where  $y$  is the distance between any point within the transition region and the  $p$ -region boundary. Electron effects are negligible for the bulk concentration of majority holes  $p_p$  is much higher than that of majority electrons  $n_n$ . Using Poisson's equation of electrostatics,  $\delta\psi$  can be found by assuming an exponential distribution for  $p_0(y)$  and  $p_1(y)$ . Thus

$$d^2[\delta\psi(y)]/dy^2 = -(q/\epsilon)p_p[e^{-a_1y} - e^{-a_0y}] \quad (8)$$

where  $\epsilon$  is the crystal dielectric constant, and  $a_0$  and  $a_1$  are constants determined from the boundary conditions that  $p_0(w) = p_n$ , and  $p_1(w) = p_e$ . Here  $w$  is the width of the junction. For most cases of interest,  $p_p \gg p_e$ . Consequently, it can be shown that, regardless of the injection intensity,  $w$  will remain nearly constant; and  $\delta\psi$  will be almost entirely contributed by the positive portion of the junction dipole charge, which will be much wider than the negative portion. These two properties considerably simplify solving equation (8) for  $\delta\psi$ , which may be written as

$$\delta\psi \simeq \delta\psi^* [\ln^{-2}(p_p/p_e) - \ln^{-2}(p_p/p_n)] \quad (9)$$

$$\delta\psi^* = qp_p w^2/\epsilon \quad (10)$$

The arbitrary constant encountered in solving the differential equation has been evaluated from the condition that the reversible electrostatic field vanishes at the  $n$ -region boundary.

Fig. 1 represents sets of theoretical and experimental forward  $V$ - $I$  characteristics for germanium, silicon and gallium-arsenide alloy  $p$ - $n$  junctions. The theoretical characteristics are either plots of equations (4) or (6). Table 1 shows all the constants for the germanium and silicon diodes used in plotting equation (6).

The generalized field theory and experiment appear to be generally in good agreement. The experimental

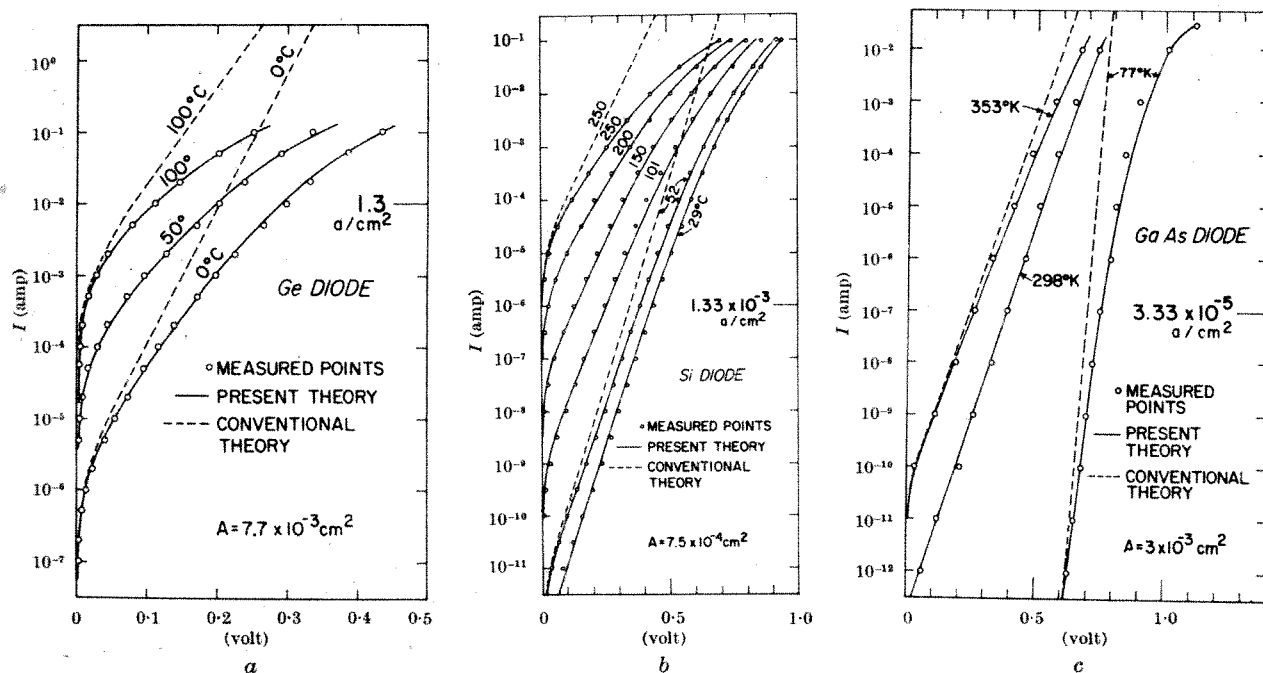

Fig. 1. Theory and experiment are compared for three different forward-biased alloy  $p$ - $n$  junctions. The theoretical curves are based on Shockley's 1949 conduction mechanisms<sup>4</sup> and either the generalized field theory or the conventional concepts of equilibrium and nonequilibrium. The germanium diodes are made by G.E.C., USA (Type 1N91). Experiments on the silicon and gallium-arsenide diodes were conducted by Sah<sup>6</sup>, and by Rediker and Quist<sup>8</sup>, respectively.

Table 1. PHYSICAL CONSTANTS FOR THE GERMANIUM AND SILICON DIODES

$T (^{\circ}\text{C})$	$p_n(\text{cm}^{-3})p$	$I^*$ (amp)	$\delta\psi^*$ (volt)
Germanium diode			
	$p_p = 5 \times 10^{18}/\text{cm}^3$ , $n_n(28^{\circ}\text{C}) = 9.13 \times 10^{12}/\text{cm}^3$		
0	$2.74 \times 10^{11}$	$3 \times 10^{-4}$	7.68
50	$3.79 \times 10^{11}$	$1.1 \times 10^{-4}$	3.93
100	$5.55 \times 10^{11}$	$1.5 \times 10^{-3}$	2.9
Silicon diode			
	$p_p = 3.75 \times 10^{20}/\text{cm}^3$ , $n_n(28^{\circ}\text{C}) = 8 \times 10^{14}/\text{cm}^3$		
29	$2.18 \times 10^5$	$7.5 \times 10^{-13}$	23.5
52	$6.72 \times 10^5$	$8 \times 10^{-12}$	17.5
101	$3.12 \times 10^9$	$1.8 \times 10^{-9}$	15.0
150	$5 \times 10^{11}$	$8 \times 10^{-8}$	11.0
200	$1.83 \times 10^{12}$	$2.0 \times 10^{-6}$	10.4
250	$5 \times 10^{14}$	$2.1 \times 10^{-4}$	8.16

points for the gallium-arsenide diodes seem to be, however, somewhat higher than the theoretical ones between  $10^{-6}$  amp  $< I < 10^{-2}$  amp. This is believed to be caused by the measuring techniques. According to Rediker and Quist<sup>9</sup>, direct current was used in the experiment except for the highest one or two points. For these points a pulsating current was used specifically to reduce heat generation. Conceivably some heating gradually developed when the d.c. current exceeded  $10^{-6}$  amp. This effect was clearly observed in our measurements on the germanium diodes, and adequate precautions had to be taken.

## Discussion

Conduction electrons and valence holes in  $p$ - $n$  junctions represent particularly interesting examples of heterogeneous thermodynamic systems. The degree of carrier heterogeneity in such semiconductor structures can, in some cases, rarely be exceeded in other systems. For example, in the silicon diodes, the characteristics of which are shown in Fig. 1b, in equilibrium and at  $29^{\circ}\text{C}$ , the hole concentration varies from  $p_p = 3.75 \times 10^{20}/\text{cm}^3$  to  $p_n = 2.18 \times 10^5/\text{cm}^3$  through a junction width of only a few hundred angstroms. When the forward current increases from  $I = I^* = 7.5 \times 10^{-13}$  amp to  $I = 10^{-1}$  amp, the concentration of injected minority holes increases gradually from  $(2 p_n)$  to more than  $(10^{11} p_n)$ . By increasing the temperature from  $29^{\circ}$  to  $250^{\circ}\text{C}$ ,  $p_n$  increases by a factor exceeding  $10^9$ . Thus analysing conduction in  $p$ - $n$  junctions on the basis of the conventional and proposed concepts of thermodynamic nonequilibrium provides an especially interesting means for checking some important consequences of these concepts directly by experiment under widely varying conditions in strongly heterogeneous systems.

Equation (6), derived on the basis of the generalized field theory, involves three fundamental quantities. The first,  $kT \ln(1 + \alpha) = qV_1$ , is the closed-loop line integral of the rotational reversible diffusion force  $\mathbf{f}_d$ . This force exists only in the heterogeneous interfaces. It must become irrotational everywhere in equilibrium. Thus under such conditions,  $V_1$  must vanish, as may be observed when  $\alpha$  tends to zero. The second quantity in equation (6) is  $kT[1 - (1/\alpha)\ln(1 + \alpha)] = qV_2$ . This term equals the closed-loop line integral of the irreversible diffusion force  $\mathbf{f}_d$ . This force only exists in the excess-charge (homogeneous)  $n$  region. Because in equilibrium there can be no irreversible transport processes, this force must then vanish, and also its line integral,  $qV_2$ , as may be seen when  $\alpha$  tends to zero. The third quantity is  $(q\delta\psi)$  which equals the closed-loop line integral of the rotational reversible electrostatic force  $\mathbf{f}_e$ . This force only exists in the heterogeneous interfaces. In equilibrium  $\mathbf{f}_e$  must become irrotational everywhere so that  $\delta\psi$  must vanish. This conclusion is confirmed by equation (9). Thus each one of the reversible and irreversible transport processes in the system verifies the new generalized conditions of equilibrium<sup>1,2</sup>. Furthermore, the new generalized principle of detailed balancing is clearly satisfied.

In a recent article, Professor McLellan<sup>11</sup> has stated that the diffusion force  $\mathbf{f}_d$ , used in the generalized field theory, would not account for the energy caused by the change of volume when particles are transported in a heterogeneous isothermal system. He has therefore

concluded that the basic arguments presented in references 1, 3 and 12, the proposed concepts of nonequilibrium and the consequent  $p$ - $n$  junction theory, would not be valid. There are at least two reasons supporting the statement that, under isothermal conditions,  $\mathbf{f}_d$  indeed accounts for whatever relates to the process of a thermodynamic nature, and only that process—not the electrostatic one, for example. Specifically,  $\mathbf{f}_d$  accounts for the work associated with the change in the particle transport potential energy and thermal kinetic energy. These new transport concepts do account fully for the energy change caused by the change in volume. The first reason actually follows from a careful understanding of the subtle arguments, and the derivations of  $\mathbf{f}_d$  and  $\mathbf{f}_e$  presented in references 1, 3 and 12. The second and more conclusive reason is clearly implied by the precise, general agreement of the new  $p$ - $n$  junction theory and experimental measurements, as may be observed in Fig. 1. In this figure, it can be also seen how the conventional  $p$ - $n$  junction theory which is directly based on the conventional concepts of nonequilibrium compares with experimental observations. Comparison of equations (4) and (6) clearly shows that the generalized field theory has introduced, rather than overlooked, two significant energy terms, which cannot possibly be accounted for through the conventional concepts of equilibrium and nonequilibrium and the basic conduction mechanisms assumed by Shockley<sup>4</sup> in 1949. These conduction mechanisms, however, have proved conclusively here to be fully satisfactory, and need none of the numerous drastic changes introduced in the past eighteen years in order to bring about, but severely restricted, qualitative or quantitative piecewise agreement between theory and experiment.

As predicted by the generalized field theory, and clearly observed in Fig. 1, the deviation between the conventional theory and experiment becomes more serious at higher current densities for more heterogeneous junctions, that is, wider semiconductor energy gaps and lower temperatures. Thus the most extreme deviation in the shown characteristics occurs in the gallium-arsenide diode at  $T = 77^{\circ}\text{K}$ , and  $V \approx 1.1$  volt. Under such conditions the conventional theory overestimates the experimentally measured current by about  $10^{20}$  times.

In conclusion, predictions of the generalized field theory should be expected in general to deviate more seriously from those of the conventional concepts of thermodynamic nonequilibrium in systems with stronger reversible transport processes. Such processes become more intense with increasing heterogeneity. In isothermal homogeneous systems, however, predictions of the new and conventional concepts become, for the most part, identical.

This work was supported in part by the University of Connecticut Research Foundation. The computational part was carried out in the University Computer Center, supported in part by a grant from the US National Science Foundation. I thank Kenzo Mori and J. J. Pennella, who assisted in the germanium diode experiments and the computations, respectively, and F. E. Gentry, who communicated the physical constants of the germanium diodes.

# Structure and Organization of Actin in a Molluscan Smooth Muscle

by

J. LOWY

P. J. VIBERT

MRC Biophysics Research Unit,  
26-29 Drury Lane,  
London, W.C.2

X-ray diffraction shows that some degree of three-dimensional organization of actin exists in a molluscan smooth muscle. From X-ray patterns from this muscle and the toad sartorius, both in the living relaxed state, it can be deduced that the actin structure repeats at intervals of about 360 Å. In this respect the structure of actin may be similar in all muscles.

ELECTRON microscopy has shown that actin filaments are double helical structures composed of globular units spaced about 55 Å apart<sup>1</sup>. This structural picture is in agreement with earlier X-ray diffraction studies<sup>2</sup> on certain dried molluscan muscles. Analysis of moderate-angle patterns suggested two alternative helical actin models but the authors could not decide between them. One structure has thirteen units, the other fifteen units, in each turn of helix, giving a helical repeat of either 350 Å or 410 Å. Electron microscopy has not yet provided a consistent value for the helical repeat in isolated natural or synthetic actin filaments<sup>3</sup>. For an understanding of the contractile mechanism it is important to determine the helical repeat and, particularly, to establish whether any changes occur in the actin structure during normal contraction<sup>1,4</sup>. X-ray diffraction studies of muscles in various states have attempted to deal with these problems<sup>5-11</sup>.

We have studied actin structure in several molluscan smooth muscles; particularly the anterior byssus retractor of *Mytilus edulis* (ABRM) by X-ray diffraction. Our diffraction patterns from the ABRM in the living relaxed state show certain features which have not been seen before and which provide new information about the organization of actin filaments in this muscle.

The ABRM was studied in the living relaxed state, as well as in the dried state. The living muscle was kept taut by means of a small weight and irrigated with natural sea water at just above freezing point. We have also examined dried specimens prepared from the smooth adductor of *Pecten chlamys*, and from the pharynx retractor of *Helix pomatia*.

The X-ray source was a Hilger and Watts semi-micro-focus tube operated at 45-50 kV and 2-3 mamp. Our camera was designed by Dr A. Elliott<sup>12</sup>, and had a toroidal mirror with a nickel surface which will be described elsewhere, as well as modifications to give improved low-angle resolution. Diffraction patterns were obtained in air or in an evacuated chamber. We are indebted to Dr H. E. Huxley for suggesting the use of the latter for recording the 51 Å layer line in the actin pattern.

We have taken as the first approximation to the helical repeat of the actin structure the value obtained from measurements of the spacings of the 59 Å and 51 Å layer lines, seen most clearly in dried specimens (Fig. 1). For the living relaxed ABRM we obtain a repeat value of 369 Å. This value is the mean of measurements on ten muscles; the values range from 350 Å to 385 Å, and the standard deviation of the mean is 15 Å. For the dried ABRM, *Pecten* and *Helix* muscles, the mean values and deviations from a similar number of measurements are respectively  $356 \pm 16$  Å,  $367 \pm 18$  Å and  $373 \pm 25$  Å.

To improve the accuracy of these values for the repeat, the indices of the observed layer lines are required. With reference to the two integral helix models of Selby and Bear<sup>2</sup>, we find that for the ABRM in both the living relaxed and dried state it is possible (within the limits of accuracy stated) to index the 59 Å and 51 Å layer lines, as well as the 27 Å meridional reflection as orders 6, 7 and 13 of the repeat; but not as orders 7, 8 and 15. Thus if the former indices are correct, the values for the repeat in living relaxed and dried ABRM would be  $358 \pm 2$  Å and  $356 \pm 2$  Å, respectively. For the dried

*Pecten* and *Helix* muscles the same indexing is possible, although the agreement with the thirteen unit model is less satisfactory.

While the fifteen unit model of Selby and Bear with a repeat of 410 Å can thus be excluded for these molluscan muscles, the thirteen unit model should, in our view, only be regarded as an approximation to the true actin structure. We consider it more likely that the actin helix does not contain an integral number of units, and that the structure repeats at intervals of about 360 Å. With the present uncertainties (about 0.5 per cent) in our values for the layer line spacings, however, we cannot distinguish between a number of possible models all of which have higher indices for our layer lines, and repeat at intervals of about 360 Å.

A new feature we have seen in diffraction patterns from the living relaxed ABRM is an intensity maximum on both the 59 Å and 51 Å layer lines (Fig. 2). We take these maxima to indicate the presence of an interference function, resulting from an ordered arrangement of actin filaments, sampling the layer lines at  $1/120 \pm 4$  Å from the meridian. This value is the same as the spacing of a

Fig. 1. Dry ABRM. Distance between specimen and film was 8 cm. Exposure was 16 h ( $\times 2$ ).

Fig. 2. Living relaxed ABRM. Distance between specimen and film was 8 cm. Exposure was (a) wide angle pattern for 16 h; (b) low angle equatorial pattern (central inset) for 2 h ( $\times 3$ ).

well orientated equatorial reflexion (Fig. 2) which was first seen by Elliott and Lowy<sup>13</sup> and measured as  $122 \pm 5$  Å in the living relaxed ABRM. The equatorial reflexion was seen to streak out when the muscle died. We have confirmed this observation and noted also that the interference maxima on the 59 Å and 51 Å layer lines disappear within 48 h, whereas the equatorial reflexion (together with an increasingly prominent equatorial streak) is still present up to 6 days after the muscle has been isolated from the animal. A day or so later, the equatorial reflexion can no longer be seen clearly. The muscle ceases to contract in response to electrical stimulation 3 or 4 days after isolation.

From these observations we are led to conclude that in the ABRM there exist regions where actin filaments are organized with partial three dimensional order, that this organization degenerates about 2 days after isolation, and that two dimensional order can be maintained for up to three times as long.

Further results which indicate that the equatorial reflexion is caused by the organization of actin filaments come from experiments in which the ABRM was fixed in 70 per cent alcohol. With dried molluscan smooth muscles (similar in structure to the ABRM) such treatment was found to destroy the actin pattern<sup>14</sup>, whereas the paramyosin pattern (caused by thick filaments) shows only a little disorientation. Our experiments with the ABRM have confirmed this and show, in addition, that the equatorial reflexion degenerates at the same time as the actin pattern.

Elliott<sup>15</sup> studied transverse sections of paramyosin filaments by electron microscopy. These showed a lamellar structure, the lamellae being spaced 150–200 Å apart. Accordingly, Elliott and Lowy<sup>13</sup> suggested that the equatorial reflexion is caused by the separation of planar net structures (spaced about 120 Å apart) within the paramyosin filaments. Our results do not support this interpretation.

So far the ABRM is the only muscle in which some degree of three dimensional organization of actin filaments has been found. It will be interesting to see whether such organization also exists in other muscle types, or whether it is uniquely part of the structural specialization associated with "catch" muscles like the ABRM.

We discuss next our results for the repeat of the actin structure in other muscles. For the dried pharynx retractor of *Helix*, our result differs from that of Worthington<sup>5</sup>, who measured the 59 Å and 27 Å layer lines and obtained a value of 410 Å for the actin repeat. Our values for the layer line spacings in the *Helix* muscle cannot be indexed on this repeat.

Millman *et al.*<sup>11</sup> obtained a value of about 400 Å for the actin repeat in the ABRM and the toad sartorius muscle, both in the living relaxed state. For the toad muscle, this result was based on the assignment to the actin structure of six diffuse low-angle layer lines with spacings greater than 59 Å. Particular reference was made to a layer line near 400 Å (with intensity well off the meridian) which was observed in both the ABRM and the toad muscle, and identified as the first layer line of the actin diffraction pattern.

From measurements of the 59 Å and 51 Å layer lines, Huxley<sup>16</sup> reported a value of about 355 Å for the actin repeat in living relaxed frog sartorius muscle. He considered this to be a better estimate for the actin period than that obtained from the 400 Å layer line which, together with the other diffuse layer lines with spacings between 59 Å and 400 Å, could not straightforwardly be assigned to the actin structure (Huxley, personal communication). Using living relaxed toad sartorius muscle, we have made measurements from the 59 Å and 51 Å layer lines, which give a value for the actin repeat in the range between 360 and 380 Å. Thus, together with our results for the ABRM, our findings do not support the view that the actin period in the living relaxed ABRM and toad sartorius is about 400 Å (ref. 11).

In the living relaxed striated adductor muscle of *Pecten maximus*, Millman and Elliott (quoted in ref. 11) observed a layer line at about 463 Å and suggested that it is caused by the actin structure. In view of the foregoing considerations this interpretation is unlikely to be correct.

The conclusion is that when the same method is used to determine the helical repeat of the actin structure in different muscles examined in the same state, the value obtained is the same (about 360 Å) in muscles as different in structure and function as the toad sartorius and the ABRM. This indicates that the actin structure might be similar in all muscles, though clearly many more types will have to be examined before a firm conclusion can be reached.

In the light of our knowledge that the layer line at about 400 Å is not caused by the actin helix it becomes imperative to determine its real origin. This reflexion constitutes a puzzling feature in the X-ray diffraction pattern, considering that its spacing varies, certainly from one muscle type to another and possibly also with the state of the muscle.

We thank Professor Sir John Randall for provision of facilities, Dr A. Elliott for his help and Mr A. Fasoli for technical assistance. One of us (P. J. V.) is a recipient of an MRC training grant.

## LETTERS TO THE EDITOR

## ASTRONOMY

## Possible New Evidence bearing on the Lunar Capture Hypothesis

INTEREST in the dynamical history of the Earth-Moon system was stimulated by the calculations of Gerstenkorn<sup>1</sup>, who deduced that the Moon was originally an independent planet in a solar orbit close to that of the Earth and that it was captured into a highly elliptical retrograde terrestrial orbit of small perigee. The orbit was brought closer and its ellipticity was reduced by tidal interaction until a dramatically close encounter with the Earth flipped the Moon over into a prograde orbit, from which it has receded to its present position under the influence of tidal friction. Gerstenkorn's theory has been favourably reviewed by Alfvén<sup>2,3</sup> and very similar dynamical histories are deduced in several more recent calculations<sup>4-6</sup>. An exact estimate of the time since the very close approach of the Moon is not possible because tidal friction is dependent on several factors, including variable geometry of the oceans. Estimates vary between  $2.5 \times 10^9$  yr and  $1.4 \times 10^9$  yr (refs. 1 and 4).

During the close approach, dissipation of tidal energy within the solid part of the Earth would have been intense, greater than the dissipation by marine tides, and certainly sufficient to cause extensive partial melting in the mantle. Once the mantle had been fluidized by partial melting, however, tidal dissipation (and consequently the rate of change of the lunar orbit) would have been greatly reduced, allowing more time for heat to escape and precluding complete melting. Possibly partial melting would have been restricted to the upper mantle (which is nearer to melting than the lower mantle and also has a lower mechanical  $Q$ —that is, greater tidal dissipation<sup>6</sup>), but a dramatic disturbance, at least to the upper mantle, is an inevitable consequence of the lunar capture hypothesis. Absence of geological evidence for such a major disturbance has been regarded as a serious objection to the hypothesis and was one of the reasons which led MacDonald<sup>7</sup> to prefer a lunar origin by accretion in orbit. We draw attention here to recent lead isotope measurements, however, which we interpret as evidence for an upheaval of the kind required by the capture theory.

Published lead isotope measurements on young mantle-derived volcanics<sup>9-14</sup>, together with some unpublished measurements, are represented in Fig. 1 as a plot of lead-206/lead-204 against lead-207/lead-204. There is a clear linear relationship with a gradient distinctly less than that of the single stage zero isochron, shown as a broken line, which would apply if the sources of the volcanics had been mutually isolated since the origin of the Earth  $4.5 \times 10^9$  yr ago<sup>9</sup>. We can therefore impose two boundary conditions on the mantle as a common source for these volcanics: (1) that the lead isotope ratios were uniform at a time geologically long after the origin of the Earth; and (2) that since that time the ratio of uranium to lead has been heterogeneous, so that radiogenic lead isotopes have been added at different rates in different environments.

An estimate of this time dates either the cessation of a long period of homogeneity or a brief event, such as lunar capture, which homogenized a previously heterogeneous mantle. We refer only to homogenization of lead isotope ratios, for which partial melting with some stirring would suffice.

Fig. 1. Plot of lead-206/lead-204 against lead-207/lead-204 for lead isotope measurements on young volcanic material.

We previously estimated the time since mantle lead was isotopically homogeneous at  $2.8 \times 10^9$  yr (ref. 9). Other estimates from different data<sup>11,12</sup> range down to  $0.5 \times 10^9$  yr but the lower values were obtained from rocks with very limited isotopic ranges and are therefore of doubtful validity. Using all the data represented in Fig. 1 and allowing for open system processes, which we have considered previously<sup>9</sup>, we obtain a preferred value of  $2.5 \times 10^9$  yr. This is uncertain by at least  $0.5 \times 10^9$  yr and many more data will be needed to establish or refute our conclusion with any certainty. If the average uranium/lead ratio in the source of the volcanics has remained unaltered during a prolonged multi-stage history<sup>9</sup>, or if a simple two stage model is appropriate<sup>10</sup>, the estimate of age will be reduced. This does not affect our two essential conclusions, however, and the coincidence of the lead isotope event and Gerstenkorn's original estimate of the time of the close approach of the Moon suggests that they were the same event. If this interpretation of the lead isotope data is accepted it not only removes an important objection to the capture theory of the lunar origin but makes the alternative theory of accretion in orbit much less attractive. Accretion at 40 Earth radii, as proposed by MacDonald<sup>7</sup>, would not "switch" on an Earth tide sufficiently violent to account for the lead isotope event, for less than 20 cal/g of rotational energy would be dissipated in the Earth in the following  $10^9$  yr. Accretion at 5 Earth radii would initiate a tidal dissipation of nearly 80 cal/g in  $10^6$  yr, which would be sufficient, but the supposition that lunar material could remain in orbit at 5 Earth radii for  $2 \times 10^9$  yr before accreting (or else suddenly appear in orbit) is difficult to accept. Thus on the present evidence the capture theory of the lunar origin is to be preferred.

### Far Ultra-violet Spectra of Orion Stars

FAR ULTRA-VIOLET spectra of the brighter stars in the vicinity of  $\epsilon$  Orionis were photographed with an objective spectrograph carried to 165 km by an Aerobee 150 rocket launched from the White Sands Missile Range on September 20, 1966, at 10h 45m U.T. As with previous Princeton flights<sup>1,2</sup> the spectrograph was stabilized by a passive gyro system which limited angular motion in the dispersion direction to about  $\pm 20''$  during a 3 min exposure giving a resolution of about 1 Å.

On this occasion we flew an all reflective spectrograph for which the camera design was based on principles described by K. Schwarzschild<sup>3,4</sup>. The spectrograph is shown in Fig. 1. Light entered through a door in the side of the rocket skin towards a plane grating. The diffracted beam then went along the roll axis to a centrally located convex spherical surface 50 mm in diameter, which in turn reflected the light to a much larger concave spherical mirror with a central hole to pass the initial beam. The second mirror focused the spectra onto a concave piece of film positioned behind the first mirror. The camera was  $f/2$  with a  $12^\circ$  diameter field and the dispersion was about  $50 \text{ Å mm}^{-1}$ . With only reflective optics this system was not impaired by absorption in a transmission element. All three surfaces were specially coated with a thin layer of lithium fluoride<sup>5</sup> immediately after aluminization to improve the reflectivity at wavelengths below 1200 Å. We were able to record spectra to about 1130 Å where the optical efficiency began to drop sharply. It is hoped that more careful protection of the optics from excess humidity will improve the far ultra-violet reflectances for later flights.

Spectra of the hot stars  $\delta$ ,  $\epsilon$ ,  $\zeta$ ,  $\eta$ ,  $\iota$  and  $\sigma$  Orionis were obtained with a 181 sec exposure which is shown in Fig. 2. The Kodak 'Pathé SC5' film was developed for 3 min in D19B at 68° F.  $\gamma$  Ori also appears on the film, but its spectrum is confused by overlapping first and second orders. Very weak images of  $\theta^1$  and  $\psi$  Ori are also present.

Fig. 1. All reflective rocket spectrograph. In order from the top are the film cassette, the small convex mirror, the large concave mirror, and the plane grating. Underneath is the gyro which provides fine stabilization of the whole spectrograph in the dispersion direction. (Photo, courtesy of Perkin-Elmer Corporation.)

Fig. 2. Far ultra-violet spectra of Orion stars. Wavelengths increase towards the right. In the spectra of  $\delta$ ,  $\epsilon$ , and  $\zeta$  the strongest absorption lines and their laboratory wavelengths are C III (1176 Å), Si III (1207 Å), H I (1216 Å), N V (1240 Å), Si IV (1394 Å, 1403 Å), and C IV (1549 Å). The original film was 22.2 mm in diameter.

About fifty absorption lines have been measured in the well exposed spectra of  $\delta$ ,  $\epsilon$  and  $\zeta$ , but only the strongest lines are clearly visible in the weaker spectra of  $\eta$ ,  $\iota$  and  $\sigma$ . Absolute wavelengths have been determined from zero-order star images on the film. Fine stabilization was maintained only in the dispersion direction; the widening of the spectra to about 5.5 min of arc resulted from the drift and jitter of the Aerobee attitude control system which provided the coarse orientation of the rocket. Near the centre of the film the spectra are a little out of focus probably because part of the double-sided sticky tape used to hold the film against the concave focal surface came loose.

In each of the spectra of supergiants  $\epsilon$  (Bo Ia) and  $\zeta$  (09.5 Ib), and the bright giant  $\delta$  (09.5 II), emission lines of the Si IV and C IV resonance transitions were found near their laboratory wavelengths of 1403 and 1549 Å, respectively. Each emission is accompanied by a strong absorption line shifted to shorter wavelengths by 5–8 Å, corresponding to velocities of 1,000–1,700 km sec<sup>-1</sup> towards us. An earlier Princeton flight<sup>2</sup> had discovered these displaced absorption lines. They show that each star is ejecting mass at remarkably high velocities—up to three times the escape velocity at the stellar surface. The shifted lines are not found at visible wavelengths because the abundant ions in these hot atmospheres have no resonance lines in that spectral region, and the dilute radiation and particle densities in the expanding shell are insufficient to excite the ions to levels from which visual absorptions can occur. In the spectra of cool giants and supergiants, on the other hand, shifts of 10 km sec<sup>-1</sup> have been observed in the resonance lines of lower states of ionization<sup>6,7</sup>.

This last flight confirmed the velocity shifts for Si IV and C IV and provided profiles with much better resolution. This flight further revealed the unresolved N V resonance doublet at 1240 Å with a trace of emission and a wide, shallow absorption profile displaced to shorter wavelengths by about the same velocity. In addition, because of the extra wavelength coverage, this camera recorded for the first time the 1207 Å resonance line of Si III and the 1176 Å excited multiplet of C III, both in absorption. In each star the Si III line has a velocity

comparable with the other resonance lines while C III is displaced somewhat less. This excited line must be formed lower in the atmosphere where the density is higher and the gas is still being accelerated.

Because these three stars are typical of normal OB supergiants and bright giants, it seems very likely that rapidly expanding shells surround all such luminous stars. When a massive star evolves through this phase therefore it will gradually eject some of its matter back into the interstellar medium.

A direct determination of the interstellar atomic-hydrogen abundance between us and the Orion stars may be obtained from the strength of the conspicuous Lyman- $\alpha$  absorption features centred at 1216 Å on the stellar continua. These absorption lines are 8 Å or more wide and very highly saturated, so that radiation damping is by far the most dominant source of line broadening. (Only if turbulent motions are of the order of 1,000 km sec<sup>-1</sup> could they affect the profile.) For such a damping profile the relation of equivalent width to column density is  $N = 1.865 \times 10^{18} W_{\lambda}^2$  atoms cm<sup>-2</sup> (with  $W_{\lambda}$  expressed in Å), a relationship which is independent of any assumptions regarding the physical conditions of the interstellar hydrogen atoms. Lyman- $\alpha$  absorption and emission processes occurring in the star's outer layers or in the

immediate vicinity of the star are expected to have significantly narrower line widths, lying well within the saturate absorption region.

The tracings in Fig. 3 are intended to show the quality of the data obtained in the vicinity of the Lyman- $\alpha$  absorption for each star, as well as to illustrate the successive stages of reduction to equivalent widths. The uppermost profiles for the spectra of  $\delta$ ,  $\epsilon$  and  $\zeta$  Ori show densitometer tracings accompanied by comparison measurements of the background fog level of adjacent unexposed regions on the film. Intensity profiles were derived from the film densities using an H-D curve determined from laboratory test exposures performed several weeks after the rocket flight with the same batch of film and identical developing conditions. Measurements of equivalent widths were made on the lowest curves which are modified intensity profiles normalized to the smooth curve drawn along the continua in the middle illustrations. Adequate allowance was made for an extension of the damping wings on either side of the prominent part of the Lyman- $\alpha$  features.

The much weaker tracings obtained from  $\eta$ ,  $\iota$  and  $\sigma$  Ori do not warrant as detailed a treatment as the strong spectra. The low exposure level may be assumed to lie within a relatively linear region of the H-D curve, and

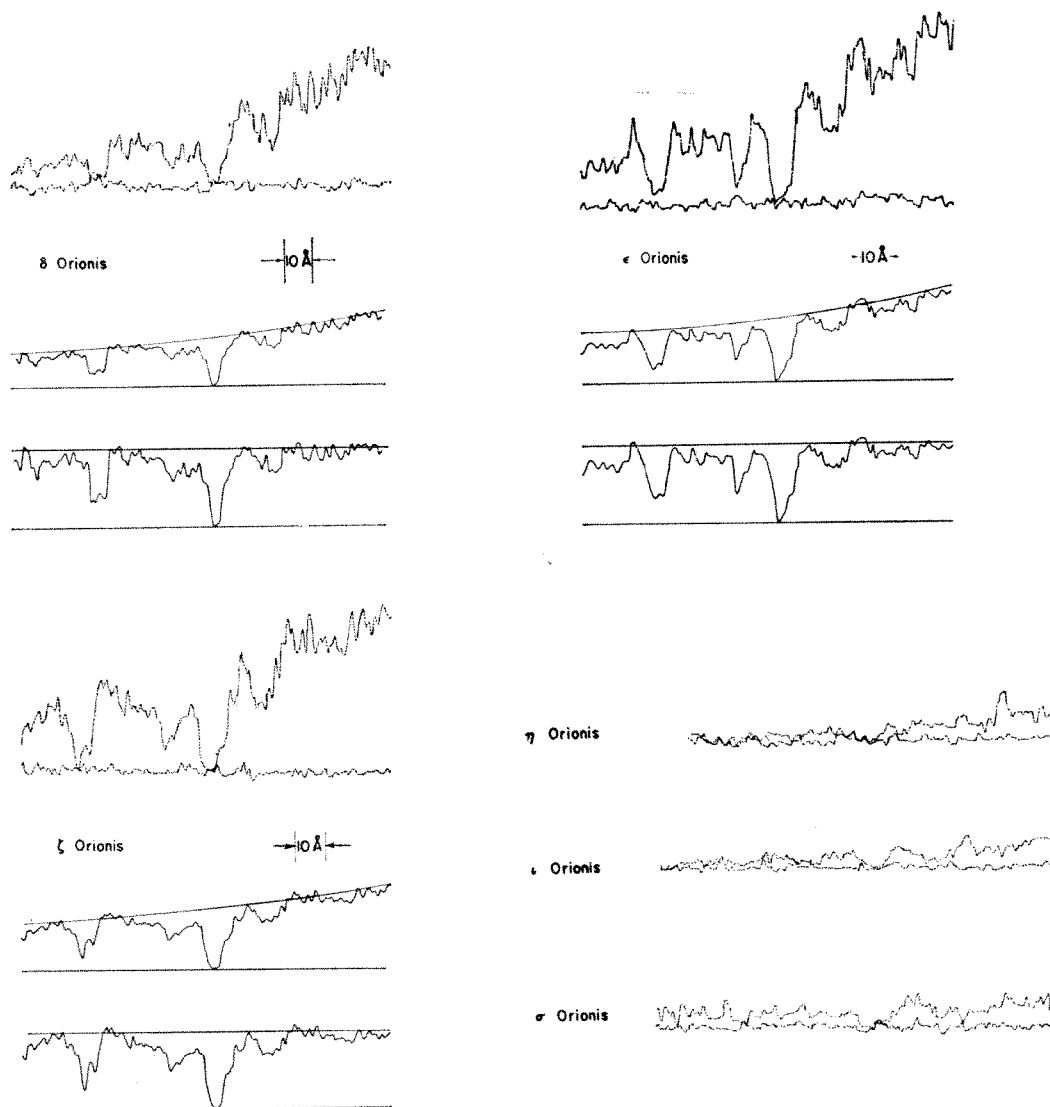

Fig. 3. Spectral scans in the region of Lyman- $\alpha$ . Wavelengths increase towards the right. Shortward of the interstellar line are the stellar lines of C III and Si III, and longward is N V. For  $\delta$ ,  $\epsilon$ , and  $\zeta$  the densitometer trace, the intensity profiles, and the normalized spectra are shown in order from the top. Only the densitometer records are given for the three faint stars.

hence the density tracings justifiably may be treated as intensity profiles. Of course, the errors in the equivalent widths are much larger with the weak spectra.

Measurements of the equivalent widths and estimates of their uncertainties, together with the corresponding number densities, are shown in Table 1. These values are consistent with the Lyman- $\alpha$  widths of about 9 Å found in  $\delta$  and  $\zeta$  Orionis by an earlier Princeton rocket observation<sup>2</sup>. The photometric quality and improved resolution of the new spectra provide much more confidence in the initial results.

Table 1. THE INTERSTELLAR LYMAN- $\alpha$  ABSORPTION LINE

Star	Equivalent width $W_\lambda$ (Å)	Column density $N$ (cm <sup>-2</sup> )
$\delta$ Ori	$8.2 \pm 1$	$1.3 \times 10^{20}$
$\epsilon$ Ori	$8.5 \pm 1$	$1.4 \times 10^{20}$
$\zeta$ Ori	$9.3 \pm 1$	$1.6 \times 10^{20}$
$\eta$ Ori	$12 \pm 6$	$3 \times 10^{20}$
$\iota$ Ori	$9 \pm 3$	$1.5 \times 10^{20}$
$\sigma$ Ori	$12 \pm 3$	$3 \times 10^{20}$

The lack of conspicuous variations in line width from one star to the next suggests that the distribution of hydrogen is not markedly irregular. The average density of hydrogen is about 0.1 atom cm<sup>-3</sup> over an assumed distance of 450 parsec<sup>6</sup> to the Orion stars. In contrast 21 cm emission measurements<sup>9,10</sup> in the Orion region have indicated values around  $1.3 \times 10^{21}$  atoms cm<sup>-2</sup>, which exceed the densities in Table 1 by a factor of ten. Likewise, 21 cm absorption in the continuum of the Orion Nebula<sup>11-13</sup> suggests that column densities in the order of  $1.5 \times 10^{21}$  atoms cm<sup>-2</sup> should be present in front of the nebula. One would not expect a substantial portion of the hydrogen seen in emission to lie beyond the Orion region, which is already about 130 parsec out of the galactic plane.

It is perhaps easier to account for our disagreement with the absorption measurements by saying that most of the hydrogen seen could be associated with the nebula or by assuming that the excitation temperature of the hyperfine transition is a great deal lower than the commonly quoted value of 125° K. Although a direct comparison with the radio data may be confused by such factors as the existence of small scale spatial or temperature inhomogeneities, it should, none the less, be evident that the difficulty in accounting fully for the discrepancy in the measurements may lead to exciting conclusions on the physical nature of the interstellar medium.

This flight of Aerobee 4.176 was supported by a contract from the US National Aeronautics and Space Administration. The payload was fabricated by the Perkin-Elmer Corporation under the supervision of Mr James Plascyk. William Harter and Kenneth Snedeker of Princeton assisted in the launch preparations.

## PLANETARY SCIENCE

### Life in the Clouds of Venus?

WHILE the surface conditions of Venus make the hypothesis of life there implausible, the clouds of Venus are a different story altogether. As was pointed out some years ago<sup>1</sup>, water, carbon dioxide and sunlight—the prerequisites for photosynthesis—are plentiful in the vicinity of the clouds. Since then, good additional evidence has been provided that the clouds are composed of ice crystals at their tops<sup>2,3</sup>, and it seems likely that there are water droplets toward their bottoms<sup>4</sup>. Independent evidence for water vapour also exists<sup>5</sup>. The temperature at the cloud tops is about 210° K, and at the cloud bottoms is probably at least 260–280° K (refs. 4 and 6). Atmospheric pressure at this temperature level is about 1 atm.<sup>7</sup>. The observed planetary albedo falls steeply in the violet and ultra-violet<sup>8</sup>, which accounts for the pale lemon yellow colour of Venus. The albedo decline would not be expected for pure ice particles, and must therefore be caused by some contaminant. Dust, ozone, C<sub>2</sub>O<sub>2</sub> and other gases may possibly explain these data but, whatever the explanation, the ultra-violet flux below the clouds is likely to be low. If small amounts of minerals are stirred up to the clouds from the surface, it is by no means difficult to imagine an indigenous biology in the clouds of Venus. What follows is one such speculation.

A macroscopic organism living in the clouds of Venus must be regulated to live at an essentially fixed altitude. If it is carried, for example by convective downdraughts to the lower atmosphere, it will encounter uncomfortably high temperatures, and if it is carried to the cloud tops it will encounter very little moisture and very low temperatures. We therefore imagine an isopycnic organism constructed as a float bladder<sup>9</sup>. Because the atmosphere is primarily carbon dioxide and nitrogen, a float bladder filled with hydrogen would be very effective. Molecular hydrogen can be produced from water by photosynthesis, as is known in purple bacteria<sup>10</sup>. Although the observed cases are for aerobes there is no reason why photosynthetic production of hydrogen by anaerobes should not occur. We consider such an isopycnic organism near the 0.5 atm. pressure level; the atmospheric density here will be about  $7 \times 10^{-4}$  g cm<sup>-3</sup>, depending somewhat on composition. The organism is essentially a spherical hydrogen gasbag with outer radius  $R_1$ , and inner radius  $R_2$ . For the organism to have a mass equal to the displaced mass of atmosphere, we require

$$5 \times 10^{-5} R_2^3 + \rho(R_1^3 - R_2^3) = 7 \times 10^{-4} R_1^3$$

where  $\rho$  is the density of the outer membrane. For  $\rho \approx 1.1$  g cm<sup>-3</sup>,  $(R_1 - R_2)/R_1 \approx 2 \times 10^{-4}$ . If the minimum skin thickness is about  $1\mu$ , as in terrestrial organisms having a dermal layer one cell thick, the gasbags have a minimum diameter of about 4 cm, about the size of a pingpong ball. Much larger organisms would also be possible. If the skin were a unit membrane thick (about 75 Å), the organism could conceivably be as small as  $75\mu$  in diameter; but this is clearly a lower limit—it is unlikely that the requisite metabolic processes could be contained within a unit membrane.

The postulated photosynthetic organism would reside just below the Venus clouds, or in the lower cloud deck. Water would be collected either as rain or by contact with the droplets, and minerals blown up from the surface would be captured on the sticky underside of the organism, and ingested by pinocytosis. The mineral requirements would be modest, and the ash content would be a very small fraction of the dry weight. Metabolic schemes can be worked out using known terrestrial biochemistry. Much smaller non-isopycnic organisms can also be envisaged. If the Stokes-Cunningham fallout times to reach moderately high temperatures are less than the replication times and if updraughts exist, a stable population of micro-

organisms may be possible<sup>1</sup>. Life at the Venus clouds can be envisaged which operates entirely on known terrestrial principles.

The conditions in the lower clouds of Venus resemble those on Earth more than any other extraterrestrial environment now known. It is possible that life arose under more moderate conditions on the surface of Venus in its early history; for example, the planet may then have been appreciably less degassed than it is today, with an atmospheric greenhouse much less effective than the contemporary one. Outgassing advanced, surface temperatures rose, and the surface became more inclement. Organisms may have then emigrated to the clouds, and may there be awaiting the first biological experiments to be performed in the vicinity of the Venus clouds.

The work reported here was supported in part by a grant from the US National Aeronautics and Space Administration.

## Lunar Diurnal Atmospheric Tide

Haurwitz and Chapman<sup>1</sup> have recently described the discovery, analysis and distribution of the lunar semi-diurnal air tide. There is, in addition to lunar semi-diurnal excitation, a smaller lunar diurnal gravitational excitation. Although there must be some atmospheric response to this excitation, it has not yet been found in the data.

The diurnal component of the lunar gravitational potential is given by Bartels<sup>2</sup> as

$$\Omega = \lambda \sin \theta \cos \theta e^{it} \quad (1)$$

where the physical quantity corresponds to the imaginary part of the expression; and  $l = 2\pi(\tau - 2S) + \varphi$ ,  $\theta$  is the colatitude,  $\varphi$  is the longitude,  $\tau$  is the time in sidereal days,  $S = \tau/\text{lunar month}$ , and  $\lambda = -19,706 \text{ cm}^2/\text{sec}^2$ . There is in addition to  $\Omega$  another lunar diurnal component the period of which is one sidereal day. The closeness of the sidereal and solar days would make the separation of this lunar component in the data very difficult.

The approximate analysis of the response of the atmosphere to the diurnal component of lunar gravitational potential is simple, and shows why the response has not yet been detected. It also suggests how one may now proceed to find it. The analysis for a thermal excitation with the same latitude dependence as (1) has been given by Lindzen<sup>3</sup>. If we ignore the difference between  $\tau$  and  $\tau - 2S$ , as it affects the solution of Laplace's tidal equa-

tion, then the extension of the analysis to gravitational excitation is immediate and yields

$$u = -\frac{i\lambda}{a\omega} e^{it} \quad (2)$$

$$v = \frac{\lambda}{a\omega} \cos \theta e^{it} \quad (3)$$

$$\delta p = \delta \rho = \delta T = \omega = 0 \quad (4)$$

where  $u$  is the northerly velocity oscillation,  $v$  is the westerly velocity oscillation,  $a$  is the radius of the Earth,  $\omega$  is the rotation rate of the Earth,  $\delta p$  is the pressure oscillation,  $\delta \rho$  is the density oscillation,  $w$  is the upward velocity oscillation, and  $\delta T$  is the temperature oscillation.

An estimate of the geomagnetic oscillation resulting from  $u$  and  $v$ , as given by (2) and (3), may be obtained from the following approximate equation derived by Baker and Martyn<sup>4</sup>

$$\frac{\partial^2 R}{\partial \theta^2} + \cot \theta \frac{\partial R}{\partial \theta} - \frac{1}{\sin^2 \theta} + \frac{\partial^2 R}{\partial \varphi^2} = \frac{aK_3}{\sin \theta} \left( \frac{\partial}{\partial \varphi} (u H_z \sin \theta) + \frac{\partial}{\partial \varphi} (v H_z) \right) \quad (5)$$

where  $R$  is the electric current function,  $K_3$  is some time and space averaged Cowling conductivity, and  $H_z$  is the vertical component of the Earth's magnetic field.

From Chapman and Bartels<sup>5</sup>

$$H_z \cong C \{ \cos \theta + \tan \theta_0 \sin \theta \cos (\varphi - \varphi_0) \} \quad (6)$$

where  $C \cong -0.6$  gauss,  $\theta_0$  is the colatitude of "equivalent" central magnetic dipole's N-pole  $\cong 11^\circ$ ,  $\varphi_0$  is the longitude of "equivalent" central magnetic dipole's N-pole  $\cong 70^\circ$  W. Substituting equations (2), (3) and (6) into equation (5) and solving for  $R$  one gets

$$R = -\frac{iK_3 C \lambda}{2\omega} \{ \sin \theta e^{it} - \tan \theta_0 \cos \theta e^{i(l - \varphi + \varphi_0)} \} \quad (7)$$

The current intensity is given by

$$U = \frac{1}{a \sin \theta} \frac{\partial R}{\partial \varphi} = \frac{K_3 \lambda C}{2a\omega} e^{it} \quad (8)$$

$$V = -\frac{1}{a} \frac{\partial R}{\partial \theta} = -\frac{iC \lambda K_3}{2a\omega} \{ \cos \theta e^{it} + \sin \theta \tan \theta_0 e^{i(l - \varphi + \varphi_0)} \} \quad (9)$$

where  $U$  is the southward (northerly) intensity, and  $V$  is the eastward (westerly) intensity. The associated variation in magnetic potential is given by

$$\Phi = -\frac{8}{3} \pi R \quad (10)$$

where differences between the distance from the Earth's centre to the dynamo layer and the radius of the Earth have been ignored. From  $\Phi$ , the magnetic field variations are obtained as follows

$$Y = -\frac{1}{a \sin \theta} \frac{\partial \Phi}{\partial \varphi} \cong \frac{8}{3} \pi U \quad (11)$$

$$X = \frac{1}{a} \frac{\partial \Phi}{\partial \theta} \cong -\frac{8}{3} \pi V \quad (12)$$

Due to the obliquity of the Earth's magnetic field there is, in addition to the component of  $R$  following the Moon, another component of  $R$  which is stationary. The same is, of course, true for the fields derived from  $R$ . Schematic representations of the velocity, current and magnetic fields are shown in Fig. 1. From Fig. 1 we see that the lunar diurnal tide may well be the simplest global dynamic system.

Fig. 1. Schematic representations of various fields for the hemisphere facing the Moon. *a*, Horizontal flow. *b*, Dynamo current (component following the Moon). *c*, Dynamo current (stationary component). *d*, Magnetic field (component following the Moon). *e*, Magnetic field (stationary component). The representations of the stationary components are for  $|\varphi - \varphi_0| < 90^\circ$ , otherwise their directions are reversed.

The observational verification of such a simple system would be gratifying. The failure to find the oscillation in surface pressure data is consistent with equation (4). The analogous result for the lunar diurnal ocean surface height oscillation, obtained by Laplace, is described by Lamb<sup>6</sup>. Whether the oscillation may be found in other fields depends on their magnitudes. Taking

$$a \cong 6.5 \times 10^8 \text{ cm},$$

$$K_3 \cong 0.8 \times 10^{-7} \text{ E.M.U.-cm},$$

$$\text{and } \omega = 2\pi/0.864 \times 10^5 \text{ sec},$$

gives

$$\left| \frac{\lambda}{a\omega} \right| \cong 0.64 \text{ cm/sec} \quad (13)$$

$$\left| \frac{1}{2} \frac{K_3 \lambda C}{a\omega} \right| \cong 1.535 \times 10^{-7} \text{ amp/cm} \quad (14)$$

and

$$\left| \frac{4}{3} \pi \frac{K_3 \lambda C}{a\omega} \right| \cong 0.1285 \gamma \quad (15)$$

From equations (2), (3) and (13) we see that there should be a wind oscillation with an amplitude of 0.64 cm/sec all over the globe. The amplitude should, moreover, be independent of altitude. From Chapman<sup>7</sup> we see that 16 years of data may be sufficient to detect an oscillation with a 1.2 cm/sec amplitude. The lunar diurnal wind oscillation might therefore be found in 64 years of data. Records of this length are available for a number of stations. From equations (11), (12) and (15) we see that both the stationary and travelling components of the magnetic field oscillation are of 0.13 $\gamma$  amplitude or less. The detection of such an oscillation might be barely possible with long data series such as are available for Greenwich Observatory. The detection is, unfortunately, rendered much more difficult by the presence of a larger oscillation with exactly the same period: the luni-solar oscillation due to the interaction of solar daily variations in electrical conductivity and the lunar semidiurnal wind oscillation. The lunar diurnal and the luni-solar oscillations can only be distinguished through their different latitude distributions, and the data necessary to do this are unlikely to be available in the foreseeable future.

In conclusion, the present theory of the lunar diurnal atmospheric tide suggests that, with available data, it will be possible to detect the lunar diurnal tide only in

wind data. Such data is now being processed for this purpose at this laboratory.

## Pyroclastic Origin of Supposed Microfossils in the Roraima Formation, Guyana

BAILEY has described some microscopic objects of apparent organic origin in material which he considered to be derived from the Roraima Formation in Guyana<sup>1</sup>. The following is an extract from his communication.

"A collection of specimens from stream pebbles and boulders at a locality on the Kako River included some which contain microscopic objects of apparent organic origin. On revisiting the locality on a later occasion an unsuccessful search for the source was made; nevertheless there is little doubt that the material was derived from the Roraima Formation. The fossil-like objects occur in chert and jasper beds. They appear to be the tests of unicellular micro-organisms and sometimes occur abundantly in very narrow bands. Examples from specimen H 265 are shown in Figs. 1 and 2. In Fig. 1 the larger of the objects, which are spherical with a suggestion of tetrahedral symmetry, has a diameter of 0.4 mm with a wall thickness around 0.008 mm. Fig. 2 contains two objects. One is a globular mass about 0.16 mm in diameter with three radiating spine-like projections, one having a length of 0.18 mm. The other object is two-chambered, each chamber being around 0.18 mm diameter with walls about 0.012 mm in thickness. In other sections a variety of forms ranging in diameter from 0.6 mm to 0.1 mm may be seen, some reminiscent of Foraminifera and Radiolaria, but none of which can be identified with any certainty. There can be little doubt, however, of their organic origin."

Because age determinations have shown<sup>2</sup> the Roraima Formation to be not younger than Lower Proterozoic, the presence of organic remains within the formation would be of considerable interest as an occurrence of life in the Pre-Cambrian. Similar microscopic objects have been figured (unpublished work, J. H.

Fig. 1. Photomicrograph of Y-shaped fragment of disrupted volcanic glass in a pebble from the Kako River, Guyana. Collection by P. B. H. Bailey, Geological Survey of Guyana (specimen H 162). (Ordinary light  $\times 172$ .)

Bisschops) subsequently from a tuff in the Roraima Formation of Surinam and "suggest relic structures of possible organic origin, although not one could be classified to date".

The present communication is not intended to comment on any aspect of the Roraima Formation but to correct the impression that the microscopic objects figured by Bailey are of organic origin. Bailey's photomicrographs were taken by me, and I have examined a number of thin sections of the "type-material", including specimen *H* 265. In my view, all the features observed under the microscope are consistent with a pyroclastic origin for these small bodies, which display the characteristic morphology of globular areas of vesiculated volcanic glass in varying stages of disruption. Conditions prevailing at the time of consolidation of the rock, as shown by the absence of "welding" effects, have favoured the preservation of occasional undisrupted bubbles which are infilled with granular quartz, epidote and fine-grained matrix material. The following petrographic observations from a classic paper<sup>3</sup> on ash-flow tuffs are equally applicable to the Guyana material.

"Tuff fragments. One widely occurring type is derived from a vesiculated glass characterized by roughly globular bubbles . . . . This material when explosively disrupted produces curved plates . . . that represent fragments of the walls of these bubbles; cusp- and lune-shaped fragments . . . ; and different forms representing the interstitial glass between several bubbles. These may be tricuspidate fragments bounded by arcs of circles, Y-shaped fragments formed in the same way . . . , and which seem to be one of the most common characteristics of glassy tuff materials. More rarely, forms which represent cross sections of undisrupted spherical bubbles have been observed . . . . The original plastic glass contained bubbles of different size, shape, and thickness of walls, and so there are many variations to the forms mentioned."

Photomicrographs from that paper and, even more convincingly, the plates accompanying an account<sup>4</sup> of a pyroclastic formation of Tertiary age from Oregon, can be matched with the features shown by the microscopic bodies in the Guyana material. A Y-shaped fragment from one of the Kako River specimens is shown in Fig. 1 and is identical in appearance with the Y-shaped shards of volcanic glass that are characteristic of vitric tuffs formed throughout geological time. There is little doubt that similar Y-shaped fragments would result from the breaking away of the three spine like projections from the globular mass in the lower part of Bailey's Fig. 2. A well formed bubble which appears to have originated through the distension of a hollow cylindrical glass body from the same specimen is shown in Fig. 2.

As far as I am aware, no micropalaeontologist has been able to identify the "supposed microfossils" and it

is unfortunate that the material was not examined in the first instance by a petrologist with appropriate experience in the petrography of pyroclastics. The morphology and size of these microscopic bodies are so characteristic of vesiculated volcanic glass that a pyroclastic origin seems to be inescapable.

### Optical Radar Detection of Backscattering from the Upper Atmosphere

A PREVIOUS communication<sup>1</sup> reported preliminary observations of atmospheric backscattering obtained with an optical radar system at the University of Maryland. The purpose of this communication is to report some of our recent results which indicate enhanced scattering near 80 km, to describe some improvements made in our equipment which have eliminated the high background noise that was evident in our earlier data and to comment on the remarks of Bain and Sandford<sup>2</sup> pertaining to these data.

The system now used is similar to that described previously but includes a rotating disk in front of the photomultiplier tube. The new shutter is synchronized with our original transmitting shutter and protects the photomultiplier during the actual firing of the laser. This protection has completely eliminated the enhanced photomultiplier noise which was caused by the high levels of light present when the laser is fired. Our noise level is now constant in time and equal in magnitude to the expected dark current plus night sky illumination.

Results have been obtained with our improved equipment during three periods since our first results were reported. We have frequently, although not always, seen enhanced scattering from high altitudes, but none as large as that we reported previously has been observed. We agree with Bain and Sandford<sup>2</sup> that the returns shown in our early data were much higher than would be expected and we now conclude that the apparent enhancement should probably be ascribed to the effects of photomultiplier overloading.

Bain and Sandford<sup>2</sup> also suggested that there might be ruby fluorescence in our early data. As we described previously<sup>1</sup>, we use the same optics for transmitting and receiving. The laser pulse is fired through an aperture in a rotating disk which is located in the focal plane of the telescope. The disk is equivalent to the shutter used by Bain and Sandford in their system. Extensive tests on our equipment, which included the use of a third shutter in front of the ruby and the firing of fluorescence only through the system, have shown that there is no fluorescence in our results. Because the original transmit-receive disk acts as the fluorescence block, the third shutter was not used when making our observations.

Fig. 1 is a profile, obtained with our improved system, showing the average return of four consecutive nights of operation. The five lower altitude points are for 50, 80, 150, 220 and 270 laser pulses respectively and the rest for 290. The variation in the number of shots for the first five points is due to the fact that our cut-on altitude depends on the initial setting of the transmit-receive shutter with respect to the laser pulse. This setting can be arbitrarily varied  $\pm 50$   $\mu$ sec when setting up for a night's observations.

Fig. 2. Photomicrograph of a well formed bubble (specimen *H* 162). (Ordinary light  $\times 172$ .)

Energy output is measured for each pulse. The average energy was about 2 Joules/pulse for the four nights reported here. The temperature of the water that cools the ruby is controlled so that there is no danger of the output wavelength (6943 Å) shifting into nearby atmospheric water vapour absorption lines.

The absolute efficiency of the system was determined by observations of  $\alpha$  UMI (Polaris) and resulted in a value of about  $8 \times 10^{-4}$  which is much lower than expected. The cause was traced to a low quantum efficiency for the EMI 9558 photomultiplier tube used in the experiment by measuring the cathode response at 6943 Å. It is possible that this same problem may be a contributing factor to the large (absolute) discrepancy between the optical radar returns observed by some other groups and the molecular curve that is predicted by the 1962 US Standard Atmosphere for altitudes below 60 km. As can be seen in Fig. 1, the profile based on our measured efficiency lies very close to the expected Rayleigh scattering curve from 45 to 65 km. The discrepancy can easily be explained by the uncertainty in atmospheric transmission and by taking the normal seasonal variation of atmospheric density into account. No attempt has been made in Fig. 1 to fit our data to the predicted molecular curve. An average (one-way) atmospheric transmission of 0.7 (for  $\lambda = 6943$  Å) was assumed when reducing raw data.

The uncertainties for the measured values shown in Fig. 1 were calculated by taking the square root of an accumulated observed pulse count for each altitude interval, and they represent the standard deviation for a Poisson distribution. Our altitude resolution, determined by the on-line computer sample rate, is 2.5 km. The last three points have been averaged over 5 km layers.

The observed value near 80 km may be interpreted as follows. If we consider our total "noise" level to be the sum of system noise and the expected molecular return for this altitude, we would expect 4.8 photoelectron counts. We observed eleven photoelectron counts. Using Poisson statistics, we may therefore conclude that there is only a 1.1 per cent chance that the observed value is the result of statistical fluctuations. If we interpret the observed

value as a real enhancement (99 per cent confidence level) then, when the profile is adjusted for a best fit over the altitude range 45–55 km, our data give a differential back-scattering coefficient of about  $8 \times 10^{-13}$  cm<sup>-1</sup>ster<sup>-1</sup>. Although this conflicts with the observations of Bain and Sandford<sup>3</sup> and Clemesha *et al.*<sup>4</sup>, it is in good agreement with Mikirov<sup>5</sup> and with estimates made by Poultney<sup>6</sup>. The enhanced echoes were not always observed. During our most recent period of access to the 20 in. telescope (January 20 to February 7, 1967), for example, they were present on February 4, 5, 6 and 7 but not on January 22, 28 or 29. The actual source of these echoes has been ascribed to *in situ* aerosols<sup>6</sup>. The alternative possibility that they are "ghost" returns caused by multiple scattering in lower atmospheric aerosols, however, should not be overlooked<sup>7,8</sup>. Variations in the molecular concentration near the mesopause from that of the 1962 US Standard Atmosphere must also be considered.

No average enhancement was observed above 85 km with any statistical certainty and our equipment is not sensitive enough at present to detect molecular scattering at these altitudes. One out of the eight computer print-outs reported in Fig. 1 shows a return from the altitude range 120–130 km. The return from this region was observed on February 7, 1967, at 0700 UT in a print-out based on fifty laser pulses and yielded a differential back-scattering coefficient of about  $5 \times 10^{-12}$  cm<sup>-1</sup>ster<sup>-1</sup>. An attempt to explain returns from this altitude region has been made on the basis of meteoritic fragmentation<sup>9</sup>.

## PHYSICS

### Supposed Anomalies in the Thermal Properties of Water and Aqueous Solutions

Falk and Kell<sup>1</sup> have recently examined some claims which have been made for the existence of "higher order phase transitions", "kinks", and "discontinuities" in the properties of water and aqueous solutions between 0° and 80° C and concluded that in every case the size of the reported anomaly was comparable with the degree of accuracy of the experiments. We have now examined a few additional physical properties for which the reported discontinuities appear at first sight to lie outside the errors of measurement, and obtained new experimental evidence on one of these—the ultra-violet absorption of aqueous solutions of iodide ions.

Briefly, we find that the claims of abnormalities in the surface tension<sup>2-5</sup> and viscosity<sup>6</sup> of water are disproved by the majority of accurate data<sup>7-15</sup>. A recent claim<sup>2-3</sup> that the activity coefficient of sodium chloride in water has a jump between 40° and 60° C is based on measurements<sup>16</sup> that have been superseded by ones that show no anomalies<sup>17-18</sup>. A claim<sup>2-3</sup> that there is a distinct discontinuity in the partial molar volume of potassium iodide in water at 15° C appears to have arisen from a mis-plotting of the results<sup>19</sup> for 12.5° and 15° C.

The most recent claim of evidence for thermal discontinuities in aqueous solutions is that of Blandamer, Fox and Symons<sup>20</sup> concerning shifts of the ultra-violet absorption of iodide ions. These authors found an irregularity at 35°–45° C in the temperature dependence of the position of the 226.3 mμ band, and observed that the irregularity became more pronounced when *t*-butyl alcohol (mole fraction *x*) was added to the system. The excitation energy  $E_{\max}$  decreased evenly with increasing temperature except in a narrow range 40°–45° C, where it was abnormally insensitive to the temperature. The effect is demonstrated by the crosses in Fig. 1, which are taken from the paper of Blandamer, Fox and Symons<sup>20</sup>. A consequence of the anomaly is that the trend of the derivative  $(\partial E_{\max}/\partial x)_T$  as a function of temperature reverses in the region 35°–45° C (ref. 20, Fig. 2).

The effect is so remarkable that we have repeated the measurements, taking careful precautions to be sure of the temperatures of the solutions and the wavelengths of the spectra. The conclusions of Blandamer, Fox and Symons rest on deviations in  $E_{\max}$  of about 0.15 kcal/mole, which corresponds to a shift of the absorption peak by 0.25 mμ. It is usually hard to achieve that accuracy, but the sharpness and high symmetry of the iodide band make it possible. We used solutions of  $1.1 \times 10^{-4}$  molar potassium iodide in 1 cm cells held in a specially constructed cell holder the temperature of which was controlled by a Colara circulating thermostat and which fitted a Beckman DK 2

Fig. 1. Transition energy for iodide ions in mixtures of water and *t*-butyl alcohol. The numbers on the curves indicate the mole fractions *x* of *t*-butyl alcohol. The dots are our data and the crosses are those of Blandamer, Fox and Symons<sup>20</sup> for *x* = 0.07.

Fig. 2. Transition energy for iodide ions in mixtures of water and *t*-butyl alcohol. The numbers on the curves indicate the temperatures in °C.

spectrophotometer. The temperatures were measured by placing a thermometer directly in the reference cell and removing it only when a record was being made. The temperatures were found to be steady to within 0.1° C during a measurement. To ensure that thermal equilibrium had been established, the records were made 20 min after the temperature in the reference cell had become steady. The wavelength scale was calibrated for every spectrum by immediately afterwards recording the 228.80 mμ emission line of a cadmium lamp (Philips 93107) on the same chart. We found that if the lamp was switched on less than a minute before its emission was recorded, a narrow line was obtained; later the line broadened and became unsuitable for accurate calibration. We consider that our results are accurate to  $\pm 0.1$  mμ, or  $\pm 0.05$  kcal/mole in  $E_{\max}$ , and these limits are considerably less than the magnitudes of the anomalies observed by Blandamer, Fox and Symons. Figs. 1 and 2 show that we found no anomaly of the kind they have reported.

Our work supports the view that there is no good evidence that water has anomalies other than the very shallow minima in its volume at 4° C and in its specific heat at 33° C, which are not discontinuities in the normal sense.

## THE SOLID STATE

### Crystal Structure of Cubic Deuterium Chloride

In an earlier communication<sup>1</sup> we stated that the X-ray powder diffraction pattern of solid deuterium chloride recorded at 118.5° K and the corresponding neutron powder diffraction pattern recorded at 111.5° K showed the same set of lines, confirming that the face centred cubic unit cell derived from the X-ray diffraction pattern was the true unit cell of the structure. Further analysis of the two diffraction patterns led to the conclusion that the observed face centred cubic structure was the statistical average of a disordered structure. The neutron diffraction pattern available at that time, however, did not provide enough information to determine the exact nature of the disorder.

On continuing this investigation, the angular range of the neutron diffraction pattern was extended to  $\theta = 35^\circ$ —the practical limit of the diffractometer—the scanning time of the diffraction pattern was increased to one week and each diffraction maximum was scanned with at least two boron trifluoride ( $\text{BF}_3$ ) counters in succession, using a bank of five counters mounted at  $10^\circ$  intervals. With these improvements it became possible to derive the integrated intensities of ten diffraction maxima with sufficient accuracy for solving the structure.

Fig. 1 shows the absolute values of the structure factors corresponding to the ten observed diffraction maxima plotted as a function of the diffraction angle  $\theta$ . It can be seen that  $|F|_{\text{obs}}$  usually decreases with increasing  $\theta$ , but this trend is reversed in two cases:  $|F(222)| > |F(113)|$  and  $|F(133)| > |F(004)|$ . These reversals are well reproducible characteristic features of the observed neutron diffraction pattern.

Of the various models tested there was only one which reproduced all details of the observed neutron diffraction pattern. In this model the chlorine atoms form an ordered face centred cubic lattice, but the orientation of the

Fig. 1. DCl,  $T = 111.5^\circ \text{K}$ ;  $\lambda = 1.059 \text{\AA}$ .

Fig. 2. Twelve-fold disordered model.

deuterium chloride molecules is disordered in the following way. The deuterium atom of each molecule has twelve equally probable equilibrium positions, situated along the lines connecting the chlorine atom of the molecule with its twelve nearest neighbours. This "twelve-fold disordered" model was refined by the least-squares method. The results of the refinement are summarized in Table 1 and the absolute values of the structure factors calculated from this model are shown in Fig. 2. The agreement of this diagram with the one in Fig. 1 is well within the experimental error.

Table 1. STRUCTURAL DATA OF DEUTERIUM CHLORIDE AT  $111.5^\circ \text{K}$

Edge length of the cubic unit cell: $a = 5.47 \pm 0.01 \text{\AA}$ .			
Space group: $Fm\bar{3}m$ ; number of molecules in the unit cell: 4.			
Fractional positional parameters of the atoms:			
	$x$	$y$	$z$
Chlorine (in 4-fold position):	0	0	0
Deuterium (1/12 atom in 48-fold position):	$0.151 \pm 0.005$	$0.151 \pm 0.005$	0
Anisotropic temperature factors of the atoms ( $B_{ik}$ in $\text{\AA}^2$ ):			
Chlorine	$B_{11} = B_{22} = B_{33} = 3.5 \pm 0.3$	$B_{12} = B_{13} = B_{23} = 0$ .	
Deuterium	$B_{11} = B_{22} = 7.5 \pm 1.5$	$B_{33} = 15.7 \pm 4.8$	
	$B_{13} = -3.6 \pm 1.8$	$B_{12} = B_{23} = 0$ .	

Final  $R$  factor after six cycles of anisotropic refinement:  $R_1 = 1.9$  per cent.

D-Cl bond length calculated from the positional parameters of the atoms:  $1.17 \pm 0.04 \text{\AA}$ .

This value is considerably less than the one reported previously<sup>1</sup> for orthorhombic DCl. This bond shortening, however, is only apparent; it is a consequence of the large molecular librations in the cubic phase.

The proposed "twelve-fold disordered" model is compatible with the results of the specific heat, infra-red and Raman spectra, dielectric constant and nuclear magnetic resonance investigations referred to in the previous communication<sup>1</sup>. It is also compatible with the results of the latest infra-red investigations<sup>2</sup>. All these investigations indicate that the cubic phase of solid deuterium chloride is disordered but none of them gives a clue to the exact nature of the disorder. Nevertheless, there is a consensus of opinion in favour of an orientational disorder which is different from the entirely random orientation of the molecules, such as one would expect if the molecules were freely rotating.

It had also been suggested<sup>3</sup>, however, that the molecules may rotate freely in the cubic phase of solid hydrogen chloride and the idea of entirely random molecular orientations for both hydrogen and deuterium chlorides has recently been revived in a modified form<sup>4</sup> which does not involve free molecular rotation. The model of randomly oriented molecules has therefore been investigated in detail. In this model the deuterium atoms were distributed over spherical shells about the chlorine atoms with the radius and the thickness of the shell as variable parameters.

It was found that this model could only be refined to a final  $R_1$  value of 4.1 per cent, thus giving a significantly

worse overall agreement with the observed neutron diffraction pattern than the "twelve-fold disordered" model. Furthermore, the model of randomly oriented molecules failed to reproduce the two observed reversals in the graph of  $|F|$  against  $\theta$ . This is shown in Fig. 3 where the vertical bars represent  $|F|_{\text{calc}}$  values giving the best overall agreement with the observed neutron diffraction pattern for the model of randomly oriented molecules. The monotonous decrease of  $|F|_{\text{calc}}$  with increasing  $\theta$  is a basic feature of this model and is independent of the values of the variable parameters.

Fig. 3. Randomly oriented model.

Disordered models with a smaller number of molecular orientations than the "twelve-fold disordered" model have also been investigated, in particular a "six-fold disordered" model in which the deuterium atoms lie along the crystallographic axes. This model led to even more unacceptable structure factors than the model of randomly oriented molecules.

Although the proposed "twelve-fold disordered" model differs significantly from the model of randomly oriented molecules, such as would result from free molecular rotation, it still allows considerable freedom in molecular re-orientation. The existence of twelve equilibrium orientations for each molecule combined with the large temperature factors of the deuterium atoms suggest that the deuterium chloride molecules carry out librations of large angular amplitudes about their equilibrium orientations accompanied by random "flipping-over" from one equilibrium orientation to another. Each "flipping over" represents a restricted re-orientation of the molecule in which a hydrogen bond to a nearest neighbour chlorine atom is broken, followed by the formation of a new hydrogen bond with another nearest neighbour chlorine atom.

We thank Mr D. H. C. Harris and the staff of the Dido reactor in supporting the neutron diffraction work carried out at Harwell. We also thank the Neutron Beam Research Committee and the Science Research Council for support.

## X-ray and Neutron Diffraction Studies of a Tetragonal Hydrogen Bronze $\text{H}_{(0.25)}\text{WO}_3$

THE unstable blue compounds obtained by the reduction of tungstic oxide with active hydrogen were classified as "bronzes" by Glemser<sup>1,2</sup> and shown by X-ray powder photography to exhibit structural variations with composition similar to those observed for the alkali-metal tungsten bronzes. In this note we report a new tetragonal hydrogen bronze phase with the same crystal structure as  $\text{Na}_{(0.1)}\text{WO}_3$  (ref. 3), and with  $0.21 < x < 0.25$ .

$\text{H}_{(0.23 \pm 0.02)}\text{WO}_3$  was prepared by passing suspensions of tungstic oxide (B.D.H., reagent grade) in 2 normal hydrochloric acid through a specially constructed Jones reductor. Both the strength of the acid and the length of the column were used to control the composition of the product, which was determined by quantitative oxidation with standard potassium dichromate solution. The deuterium analogue was prepared by an identical procedure carried out in the complete absence of air and water vapour. The products were precipitated in a centrifuge and washed repeatedly with water (or heavy water), pumped dry and transferred to evacuated sealed tubes.

A Philips P.W. 1010 generator, P.W. 1050 goniometer and P.W. 4231 counter were used to obtain accurate angles and intensities over the range  $2\theta = 0-90^\circ$  ( $\text{CuK}\alpha$ ) by step scanning at intervals of  $0.05^\circ$  and counting for 10 sec. Samples milled with silicone grease (under nitrogen) and embedded in aluminium trays maintained constant composition for 8 h. In addition a large number of powder photographs of samples, sealed under vacuum in 'Pyrex' tubes were obtained using a Debye-Scherrer camera. Neutron diffraction experiments were carried out on an AERE (Harwell) neutron diffractometer at liquid helium temperatures on samples sealed in aluminium tubes.

The X-ray diffraction data at room temperature showed that the compounds have the tetragonal lattice symmetry  $P4/nmm-D_{2h}^{19}$  (the only systematic absences are  $hk0$  with  $h+k$  odd). The lattice constants of the unit cell as obtained from powder photographs are

$$a_0 = 5.2285 \pm 0.0005 \\ c_0 = 3.881 \pm 0.001$$

with a cell content of two formula units of  $\text{H}_{(0.23)}\text{WO}_3$ . The structure factor calculations were based on the following atomic parameters

	B(A) <sup>2</sup>	
2W in 2(c)	0.70	$0\frac{1}{2}z, \frac{1}{2}0z$
20 in 2(c)	0.20	$0\frac{1}{2}(z + \frac{1}{2}), 0\frac{1}{2}(z - \frac{1}{2})$
40 in 4(e)	0.20	$\frac{1}{4}\frac{1}{4}z, \frac{3}{4}\frac{1}{4}z, \frac{1}{4}\frac{3}{4}z, \frac{3}{4}\frac{1}{4}z$

The coefficient for tungsten in the isotropic temperature factor  $B(A)^2$  was derived from intensity data obtained for a cubic hydrogen bronze  $\text{H}_{(0.48)}\text{WO}_3$ , a reasonable value for oxygen being assumed. A value for  $z$  was determined from the reflexions with  $h+k$  odd, which are most sensitive to  $z$  and approach zero intensity as  $z$  approaches  $\frac{1}{2}$ . Calculated and observed intensities are given in the table.

The positions of the hydrogen atoms in the lattice were determined from the neutron diffraction data by a comparison of the relative intensities of a hydrogen and deuterium bronze of the same composition ( $\text{H}_{(0.25 \pm 0.01)}\text{WO}_3$ ). Although line broadening prohibited a complete interpretation of the absolute intensities, it was shown that the light atoms occupy the interstitial (special) positions in the distorted perovskite lattice with the atomic parameters

$$0.5 \text{ H in } 2(a)$$

$$000, \frac{1}{2}\frac{1}{2}0$$

312	0.37525	0.37520	7.5	6.4
401	0.38710	0.38730	4.2	5.2

(Only those reflexions suitable for intensity measurement have been included.)

Although no evidence of ordering of the hydrogen atoms was found, systematic discrepancies between observed and calculated structure factors indicate that the oxygen positions may differ slightly from those given here. It is hoped that additional experimental data will enable a more precise assignment of atomic co-ordinates to be made.

The structure of  $H_{(0.23)}WO_3$  is thus identical with that of  $Na_{(0.1)}WO_3$  (ref. 3) with hydrogen atoms occupying the alkali metal positions. The former compound has also been prepared in this laboratory by the bombardment of tungstic oxide at room temperature with gas phase hydrogen atoms produced in a microwave discharge.

We thank Mr Alan Jacobson for assistance with the neutron experiments. We are grateful to the Science Research Council and AERE, Harwell, for providing neutron facilities and to the Gas Council for the award of a research studentship to one of us (R. J. H.).

## CHEMISTRY

### Metastability of Rotationally Hot Dihelium at 77° K

WE report here the detection by kinetic absorption spectroscopy of  $He_2$  ( $a^3\Sigma_u^+(\sigma=0)$ ) produced in the gas phase at 77° K with an intense microwave pulse discharge. Although vibrationally cold, at this temperature the molecules exhibit an extremely non-equilibrium distribution in the high rotational states, which show only a minor degree of relaxation during their lifetime of  $10^{-4}$  sec with total helium pressures up to 100 mm. The observations appear to constitute a unique example, as yet, in which the absorption spectrum of a rotationally hot molecule yields relative reaction rates into individual rotational states. It is suggested that the observed rotational distributions of  $He_2$  ( $a^3\Sigma_u^+$ ) may reveal the states of  $He_2^+$  ( $X^2\Sigma_u^+$ ) from which it is formed.

The single pulse microwave generator incorporated an English Electric M 578 magnetron, the pulse was switched from a 1.5  $\mu$ F condenser, with two English Electric CX 1140 thyratrons, and the output power was transmitted to a waveguide section via a "door-knob" and "double-plunger tuner". The power was coupled to the

gas at low  $Q$  (to prevent mismatch following breakdown) by positioning the quartz reaction vessel (length 1 m) inside a standard waveguide section preceded by a right-angle bend. Power is efficiently absorbed by the gas, with this arrangement. The spectroscopic light-pulse was directed through the reaction vessel onto a lens located inside the waveguide, and was extracted via a 1.5 cm hole in the broad face of the bend. For experiments at 77° K, the waveguide was filled with liquid nitrogen. Spectra were recorded with a Hilger Littrow spectrograph, and the helium was purified by cataphoresis.

In these experiments, the magnetron was pulsed at 23 kV for 3.5  $\mu$ sec with an output power of 400 kW, corresponding to a total energy of 1.4 J/pulse. The formation and decay of rotationally hot  $He_2$  ( $a^3\Sigma_u^+$ ) at 77° K are shown in Fig. 1. The total concentration reaches a maximum about 15  $\mu$ sec after termination of the pulse. The distribution shows a sharp minimum for states  $K=5, 7$  and 9, with a maximum population in levels 17 and 19. There is an abrupt cut-off of higher states, with the  $K=21$  population, one half of that in  $K=19$ ; the level  $K=23$  was just detectable. At 77° K, the plates indicate a slow but definite drift with time to lower  $K$ , though the distribution still showed extreme departure from equilibrium at the longest delay time of about 150  $\mu$ sec, at which  $He_2$  ( $a^3\Sigma_u^+$ ) could still be observed.

Similar experiments were conducted at 150° and 295° K. At 295° K, a linear variation of the log of the ratio of the plate density changes to  $2K+1$ , with the energy of the  $K^{th}$  state, was observed at all time delays corresponding to a rotational temperature of  $380 \pm 80^\circ$  K, and a "Beer-Lambert factor" of about unity. At 150° K, the initial rotational distribution was similar to that observed at 77° K, showing a double maximum, with states  $K=1$  to 5 tending to a Boltzmann distribution. The initial distribution is weighted more into the lower  $K$  states, however, with a third in states below  $K=7$ , compared with a fifth at the lower temperature. At 150° K, the rotational distribution shifts fairly rapidly with time, towards an equilibrium distribution. Relative populations at the shortest delay times are listed in Table 1.

Table 1. RELATIVE POPULATION OF ROTATIONAL LEVELS OF  $He_2$  ( $a^3\Sigma_u^+$ ) IMMEDIATELY FOLLOWING THE MICROWAVE PULSE

150	0.133	0.120	0.10	0.048	0.024	—	—
77	0.13	0.15	0.15	0.087	0.039	—	—

The derivation of the relaxation times for the individual quantum states will require an analysis of all processes which simultaneously contribute to the formation and decay of  $He_2$  ( $a^3\Sigma_u^+$ ). At 77° K and 35 mm pressure, the relaxation time in the levels 15–19 appears to be approximately 50  $\mu$ sec, corresponding to rotational relaxation once in about  $10^4$  collisions. The theoretical vibrational relaxation time at this temperature and pressure is  $10^{-6}$  sec ( $Z=300$ ) assuming a minimum in the interaction potential with a characteristic temperature of 77° K and an intermolecular force constant corresponding to 0.18 Å. Although the standard theory seems to exaggerate relaxation rates in systems of small reduced mass, the detection of  $He_2$  ( $a^3\Sigma_u^+$ ) only in  $\sigma=0$  cannot exclude the possibility that the dihelium is produced in excited vibrational states. K. Takayanagi, of Colorado University, tells us that he has estimated that there is a slightly greater vibrational relaxation rate at 298° K, and the temperature coefficient for both vibrational and rotational relaxation should be quite small. Rotational relaxation of  $He_2$  ( $a^3\Sigma_u^+$ ) in the high  $K$  states is apparently slower than vibrational relaxation, and the metastability of the rotationally hot molecules must imply that in collision

Fig. 1. The formation of  $\text{He}_2$  ( $a^3\Sigma_u^+$ ) at  $77^\circ\text{K}$ . Helium pressure 35 mm.

with atomic helium the interaction equipotential surfaces are very nearly spherical about the centre of the diatomic molecule.

It is now established that the chief reaction causing molecular emission in the early after glow of a helium discharge is collisional combination of molecular ions with electrons<sup>1-4</sup>

Departure from a Boltzmann distribution has been detected in emission at ambient temperature<sup>5,6</sup>. Collisional combination and subsequent cascade radiation should occur without changing substantially either the nuclear separation or the rotational energy. Because rotational relaxation of  $\text{He}_2$  ( $a^3\Sigma_u^+(\sigma=0)$ ) is slow at  $77^\circ\text{K}$ , the observed distribution must correspond closely to that of the molecular ion. Considering such a scheme in further detail, there are several features which are difficult to interpret and will require further study. Following the theory of Stabler<sup>6</sup>, the rotational excitation probably results from multiple non-combinative encounters of  $\text{He}_2^+$  ( $\sigma=0$ ) with electrons during the discharge, the cut-off above  $K=23$  may reflect the instability of the rotationally hot molecular ion in the environment. The principal difficulties concern the slow rate of formation of  $\text{He}_2$  ( $a^3\Sigma_u^+$ ) following the pulse (a similar problem has been discussed in relation to molecular emission following a pulsed discharge<sup>7,8</sup>) and also the invariance of the distribution with time at  $150^\circ\text{K}$ , immediately following the pulse.

## Decomposition of Nickel Oxide

DURING recent studies of photo-adsorption on high area nickel oxide, decomposition of the oxide was observed at surprisingly low temperatures. Teichner<sup>1</sup> first prepared this nickel oxide by decomposing  $\text{Ni}(\text{OH})_2$  at  $200^\circ\text{C}$  for 2 h at a pressure of less than  $10^{-5}$  mm mercury. It is yellow-green, with a surface area of approximately  $100\text{ m}^2\text{g}^{-1}$  and has a composition which is almost stoichiometric<sup>2</sup>. Both composition and area are little changed by further annealing under the same conditions, but on exposing the oxide to higher pressures of oxygen, it blackens instantly.

If oxygen (at a  $p_{\text{O}_2}$  of 0.06 mm) has been adsorbed to completion on the oxide in the dark at  $120^\circ$  and  $200^\circ\text{C}$ , and the surface is illuminated with water filtered, white light from a Philips 12 V 100 W tungsten lamp, oxygen begins to be rapidly evolved at both temperatures so that after 30 min several times as much oxygen is evolved as has been adsorbed in the dark. The oxide decomposes and metallic nickel is easily detected in the darkened patches of the oxide. Apart from two precautionary comments about thermal decomposition of this oxide at  $400^\circ\text{C}$ <sup>1,2</sup>, and a study by Imoto *et al.*<sup>3</sup> on an unspecified oxide between  $660^\circ$  and  $780^\circ\text{C}$ , no other reports of decomposition of NiO at low temperatures have appeared. Furthermore, the thermodynamic data give  $K_p^{400^\circ\text{C}} = p_{\text{O}_2}^{1/2} = 10^{-14}\text{ atm.}^{1/2}$ , that is, the equilibrium oxygen pressure at this temperature is  $10^{-28}$  mm of mercury.

More controlled experiments without prior dark adsorption showed rapid decomposition (8 per cent in 1 min) of the freshly prepared oxide at  $200^\circ\text{C}$ . After 30 min, 25.65 per cent of the oxide had reacted, although the rate had now slowed to 0.1 per cent decomposition  $\text{min}^{-1}$ . At lower temperatures decomposition was slower, until at room temperature it was much smaller (0.55 per cent in 25 min) but still quite definite. When annealed oxide samples (10 h at  $200^\circ\text{C}$ ) were used, however, the decomposition at each temperature of illumination was reduced to about 10 per cent of that for the freshly prepared samples.

The thermal decomposition of this form of nickel oxide was investigated by raising the temperature slowly in the dark above  $200^\circ\text{C}$  at  $10^{-6}$  mm of mercury. At  $340^\circ\text{C}$  the first oxygen appeared and 2.84 per cent decomposition occurred in 5 min, followed by a further 8.5 per cent in

5 min when the temperature was raised to 370° C. Thus if the decomposition of the illuminated surface is caused by thermal heating of the sample, rather than some truly photoprocess, the hot spots on the illuminated surface must exceed 350° C. A rise of only 2° C was detected, however, on a thermocouple immersed in the sample.

The dark and illuminated decompositions indicate that this oxide has very different thermodynamic properties from low area and bulk NiO. Furthermore, the stability of the fresh oxide differs from that of the annealed oxide, even though these oxides otherwise seem to have similar surfaces and properties.

Several models have been considered to account for these observations. The first model implies that the oxide has a very defective lattice structure with clustered vacancies which might lead to decomposition; but X-ray and electron diffraction studies of the oxide give no encouragement to this model. A second model is based on stored energy for the tiny crystallites may incorporate unrelaxed cubic-to-rhombohedral structures and stacking faults. Attempts to analyse the diffraction line shape for such features were unsuccessful because of the superimposed effect of the particle size. Furthermore, for very similar systems, this type of excess energy has never exceeded 1–3 kcal mole<sup>-1</sup> (ref. 4), whereas a value of at least ten times this amount is required for decomposition of the NiO at 500° K ( $\Delta G^\circ = 10$  kcal mole<sup>-1</sup> compared with  $\Delta G^\circ$  (bulk oxide) = 47 kcal mole<sup>-1</sup>).

The third and most likely model is based simply on the size of the crystallites and the surface arrangements at these low temperatures of formation. For the average crystallite size observed in the oxide, at least 10 per cent of the ions are surface ions, the co-ordination of which depends on the particular packing.

The lattice energy of an ionic crystal is large compared with the enthalpy, and thus the free energy, of formation and small changes in the former can cause large changes in the latter.

Preliminary calculations on model ionic crystallites bounded by (111) and (100) planes respectively suggest that there are variations in lattice binding energy which could account for the observed phenomena. The effect of the annealing would then be to cause simple intracrystalline rearrangements of the surface atoms by increasing their co-ordination and their stability without changing the surface area.

We thank the International Nickel Company for support and Dr I. M. Ritchie for valuable discussions.

### Desorption of 3-Phenylpropionaldehyde preceding Polarographic Reduction

In the interpretation of polarographic measurements, it is usually assumed that organic compounds are only reduced when they are adsorbed onto the surface of the mercury electrode<sup>1,2</sup>. Unfortunately, the term "adsorption" is used for a broad range of interactions between the solid and liquid phase.

Two of the simplest electrochemical methods which are assumed to indicate the potential range over which

adsorption occurs, are the change in capacity current on d.c. polarographic curves<sup>3</sup> and the presence of tensametric peaks<sup>4</sup> in a.c. polarography. In many previously reported cases, there have been changes in the double layer, associated with adsorption/desorption effects, at potentials so near to the potential corresponding to a faradaic process that it was difficult to separate the components affecting the a.c. polarographic curves.

3-Phenylpropionaldehyde exhibits good resolution between the adsorption/desorption phenomena and the faradaic reduction process.

The d.c. polarogram comparing the capacity current of the pure buffer and the buffer in the presence of aldehyde (Fig. 1) shows a well defined region between -0.2 V (Fig. 1, potential A) and -1.4 V (potential D) where the capacity current in the presence of the aldehyde is below that of the pure buffer. The reduction wave occurs at a more negative potential (-1.64 V) than the desorption potential (-1.4 V).

The a.c. polarographic curves of the same solutions (Fig. 2) show a decrease of the a.c. current below the value of the pure supporting electrolyte between -0.1 V and -1.42 V (potential D, Fig. 2). The reduction peak (R) at -1.6 V is therefore preceded by a potential region in which the curves of the pure buffer and aldehydic solution overlap. The nature of the indistinct peaks of -0.8 V and -1.2 V is being investigated.

Thus both methods suggest that 3-phenylpropionaldehyde is adsorbed at about -0.1 V and is desorbed at about -1.4 V. The reduction at -1.65 V must therefore occur at a potential at which the compound is usually considered to be desorbed. Such behaviour might be more common than is usually assumed—for example, benzophenone in 60 per cent ethanol also shows no decrease in the a.c. polarographic curve before the reduction peak (Fig. 2b in ref. 5).

3-Phenylpropionaldehyde is therefore a suitable model for the study of adsorption/desorption phenomena.

Fig. 1. D.C. polarographic curves of 3-phenylpropionaldehyde. (1) Borate buffer, pH 9.2; (2)  $1.5 \times 10^{-4}$  molar 3-phenylpropionaldehyde in borate buffer, pH 9.2. Curves start at 0.0 V.

Fig. 2. A.C. polarographic curves of 3-phenylpropionaldehyde. (1) Borate buffer, pH 9.2; (2)  $1.5 \times 10^{-4}$  molar 3-phenylpropionaldehyde in borate buffer, pH 9.2. Curves start at 0.0 V.

because it is a relatively simple molecule and is sufficiently soluble, and particularly because it shows a clear separation of the capacity and faradaic processes.

## BIOLOGY

### Seasonal Variation of Caesium-137 from Fallout in a Clam, *Rangia cuneata* Gray

In the northern temperate zones, fallout of long lived radionuclides, including caesium-137, varies seasonally, with a maximum during May–June and a minimum during November–December<sup>1</sup>. The concentration of caesium-137 in caribou flesh and in Alaskan Eskimos shows a similar seasonality<sup>2</sup>. Because of its half life of 30 yr and the huge stratospheric reservoir of radioactive debris, the amount of caesium-137 on the surface of the Earth is still increasing, despite the moratorium on atmospheric testing<sup>3</sup>. Although caesium is not a biologically important trace element, chemically it resembles potassium, which is the principal cation of cytoplasm. The bioaccumulation of caesium has therefore aroused considerable interest<sup>4,5</sup>. Whereas the concentration of caesium in marine organisms

is usually about three to thirty times higher than in the surrounding water, the concentration for similar organisms in fresh water may be higher by a factor of 100–1,000 (ref. 5). In laboratory experiments with isopods and snails from brackish water, Bryan<sup>6</sup> showed that the biological concentrations of caesium and potassium were directly related and that the concentration factors of both elements were inversely related to the salinity of the water. In the field study reported here, a bivalve mollusc, *Rangia cuneata* Gray, was collected from six stations in the Trent–Neuse estuary in eastern North Carolina (Fig. 1), and the amount of caesium-137 in the soft tissues was measured periodically for 18 months.

The Neuse River drains some 6,000 square miles of the central Piedmont region and coastal plain of North Carolina and receives radioactive pollution only from worldwide fallout. The Trent, a principal tributary, enters the Neuse at New Bern. *Rangia* is collected on a limited scale for human consumption in some estuaries of North Carolina; it is found fairly abundantly on sandy bottoms throughout the sampling area in salinities ranging from <0.1 to >15 parts per thousand (Fig. 1). *Rangia* were collected at the stations once every 4–6 weeks, the shells were scrubbed and rinsed at the laboratory, and the clams were opened by steaming in a stainless steel bucket on a hotplate. Soft tissues were ashed at 450° C and subjected to gamma-ray spectrometry for analysis of radioactive content<sup>7</sup>. Caesium-137 from fallout and naturally occurring potassium-40 were determined as the sums of the counts comprising their respective photopeaks at 0.662 and 1.46 meV (five 20-keV channels) for a 200-min analysis after correction for background and after spectral stripping of other gamma emitting radionuclides<sup>8</sup>.

The ratio of caesium-137 to potassium-40 in *Rangia* at the four upstream stations exhibited a pronounced seasonal cycle which was not so apparent in clams from Pinecliff or Cedar Point. The salinity of the water, which was measured coincidentally with the collection of each sample, also varied seasonally, and reflected an inverse

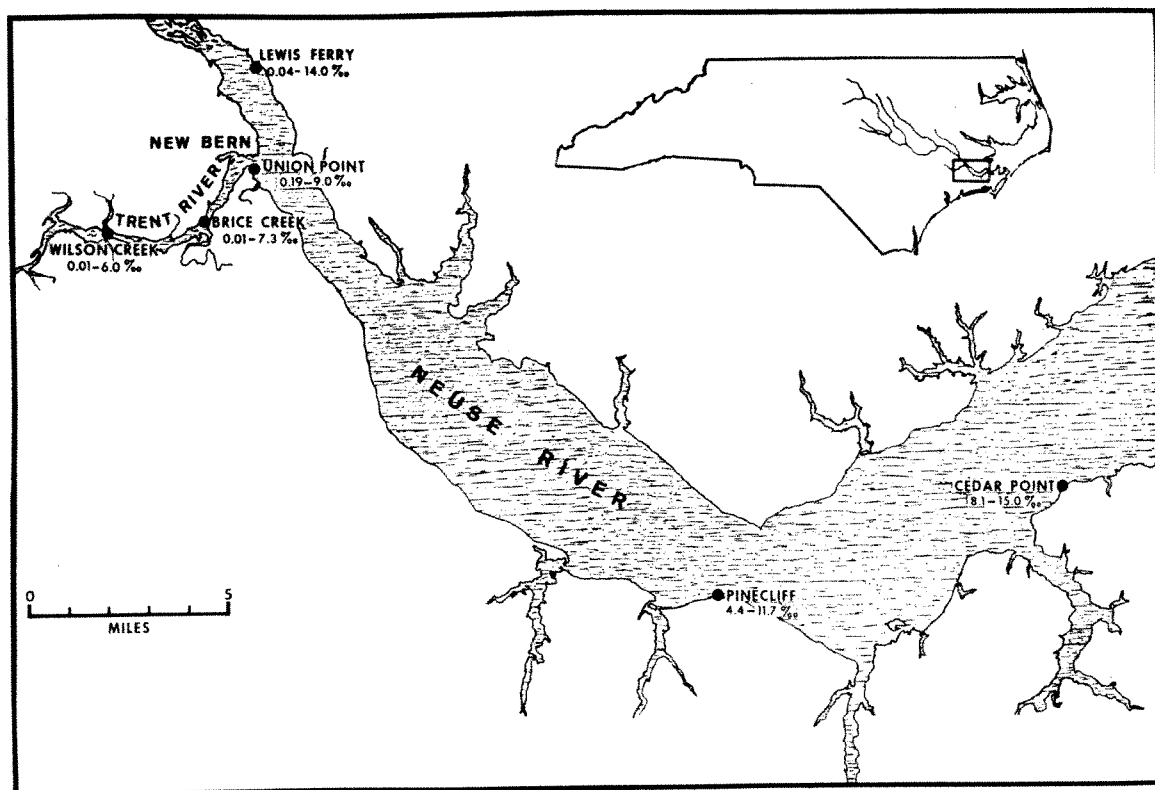

Fig. 1. Location of sampling stations for *Rangia cuneata* in the lower Trent and Neuse Rivers. Measured extremes of salinity are shown for each station.

relationship to the caesium-137/potassium-40 ratio in *Rangia* (Fig. 2). Although the salinity, and therefore the potassium content, of the water was quite different at the six stations (usually <1 part per thousand at Wilson and Brice Creeks and 5–15 parts per thousand at Pinecliff and Cedar Point) the concentration of potassium-40 in the tissues of *Rangia* increased only two-fold with salinity (Fig. 3). In Bryan's<sup>6</sup> laboratory experiments, the potassium content of brackish water isopods (*Sphaeroma*) was also stable over a wide range of salinity, and the variability of potassium content at any given salinity was similar to that for *Rangia* (Fig. 3). Because concentrations of potassium are essentially constant, the variation in the ratio of caesium-137 to potassium-40 chiefly represents changes in the concentration of caesium-137 in the clam. In late spring, when the ratio of caesium-137 to potassium-40 attained its highest value at each station, the concentration of caesium-137 in *Rangia* decreased from station to station in a downstream order (Wilson Creek  $\approx$  Brice Creek > Lewis Ferry > Union Point > Pinecliff  $\approx$  Cedar Point). The greatest difference in caesium-137 content between clams from upstream and downstream stations was six- to seven-fold. The absolute activities of caesium-137 in *Rangia* ranged between 0.93 pc. (Cedar Point, February 9, 1966) and 8.33 pc. (Wilson Creek, May 18, 1966)/100 g wet weight, and averaged for all samples  $2.79 \pm 1.55$  pc./100 g wet weight<sup>8</sup>.

The seasonal fluctuations of caesium-137 content of *Rangia* may be promoted simultaneously by two phenomena, both of which are correlated with rainfall: (a) seasonal variation in the quantities of radioactive debris deposited in the biosphere; and (b) seasonal variation in the salinity (potassium content) of the river water at the sampling stations. The variation of caesium-137 in *Rangia* from upstream corresponded closely to the five-fold range reported for seasonal variation of atmospheric

Fig. 3. Least squares regression for the relation of potassium-40 in *Rangia cuneata* to salinity of the water where the clams were collected. Dashed lines are the 95 per cent confidence limits for the regression line.

fallout<sup>1</sup>. The five-fold range of caesium-137 concentration in *Rangia* for a salinity change of more than eighty-fold (from <0.1 to about 8 parts per thousand at Brice and Wilson Creeks) is not consistent with published results of laboratory experiments. Bryan<sup>6</sup> showed that the concentration of caesium-134 in the crab *Carcinus maenas* is inversely proportional to the concentration of potassium of the water. A similar relationship exists for the concentration of caesium-137 by snails and isopods from various dilutions of sea water<sup>5</sup>. At the nearly freshwater stations in the lower Trent and Neuse Rivers therefore the seasonal variation of caesium-137 in *Rangia* is probably caused principally by fluctuations in the deposition of fallout.

If the concentration of caesium-137 was the same in the water at all stations, the concentrations of caesium-137 in *Rangia* at Wilson Creek might be expected to be much higher in relation to those at Cedar Point than were observed. I therefore surmise that the concentration of caesium-137 is much lower in the fresh water of the Trent River than in the estuarine waters of the Neuse, and that this difference accounts for the lack of inverse proportionality between salinity and caesium-137 in *Rangia* at any one sampling time. Because the bioaccumulation of caesium-137 is influenced by the content of potassium in the water, however, estimates of potential concentrations of radiocaesium in estuarine organisms should allow for seasonal and perhaps even tidal variations in salinity.

This work was partially supported by contract from the US Atomic Energy Commission. I thank T. A. Miner, J. Lewis, T. G. Roberts and J. A. Baker for assistance in the collection and preparation of samples.

## Variation of Strontium Content within Shells of Recent *Nautilus* and *Sepia*

OUR survey of the strontium content of aragonite shells from living and fossil cephalopods<sup>1</sup> has prompted us to make a more detailed study of the variations of strontium concentration within individual shells of two familiar species now extant—*Sepia officinalis* and *Nautilus pompilius*. Preliminary analysis revealed marked difference in the strontium content of the dorsal and ventral components of the aragonite sepium or cuttlebone of *Sepia*, and so we have investigated in detail samples of these specimens from different parts of the two components of the shells. Most of this communication is, however, concerned with the analyses of samples from two specimens of *Nautilus*. Altogether we have made 350 determinations of strontium, using an X-ray fluorescence technique<sup>1</sup>. All samples were analysed in duplicate and the precision error ranged from  $\pm 1.8$  to  $\pm 2.5$  per cent.

The ventral component of the *Sepia* cuttlebone is the highly porous chambered phragmocone, which is covered dorsally by a thin aragonitic periostracum. Material from the phragmocone was mostly obtained by taking 2 cm<sup>2</sup> of aragonite from various parts of the surface, penetrating the cuttlebone to a depth of 1 cm. In two specimens, some material was obtained from the interior of the phragmocone. Samples from the periostracum were obtained by choosing an area of approximately 1 cm<sup>2</sup> at various positions along the length. All material was ground to pass 200 mesh and analysed for strontium. Subsequently they were treated with a 5 per cent sodium hypochlorite solution to remove organic matter (compare ref. 2) and re-analysed for strontium.

The data for *Sepia* are presented in Table 1. The first figure for each sample gives the value before treatment for the removal of organic matter; the second figure, in parentheses, gives that after such treatment.

Table 1. VARIATION WITHIN *Sepia* OF STRONTIUM

Specimen		Anterior	Anterior/central	Central	Posterior/central	Posterior

	Phragmocone	Interior 2,520 (2,800)	—	2,530 (2,900)	—	—
3	Periostracum	3,020 (3,260)	—	3,180 (3,560)	—	—
	Phragmocone	Interior 2,360 (2,580)	2,390 (2,600)	—	2,360 (2,380)	2,370 (2,550)
		Exterior 2,930 (3,280)	2,760 (3,240)	—	2,900 (3,440)	3,050 (3,960)

Values are given in p.p.m.

The values for the periostracum show only slight variations, both within individual specimens and before and after hypochlorite treatment.

Values for the phragmocone are consistently larger, ranging up to 4,100 p.p.m. in treated material, and there is appreciably more variability. The variation within each specimen must relate to differences in strontium deposition during the growth of the animal, allowing for the fact that the chambers lie oblique to the length of the cuttlebone. The data for treated specimens 1 and 3 indicate a decline in strontium values, followed by an increase, between the earliest- (posterior) and latest-formed parts of the phragmocone.

For the principal part of our investigation we used two mature, sagittally sectioned specimens of *Nautilus* which we labelled A and B, 16.1 and 15.9 cm maximum diameter, respectively. Samples of septa were obtained by drilling midway between the septa necks and the venter. Because of the small size of the early septa the whole area between these two positions had to be used for analysis. Venter material was taken at positions adorally 140° from particular septa, thus producing a number of septum/venter pairs, secreted at about the same time. Although most septa were sampled, septum/venter pairs of only the outer whorl were obtained, because it is

difficult to obtain venter material where it is bounded by the preceding whorl. All samples were ground to pass 200 mesh and treated with sodium hypochlorite before strontium was determined.

The data for *Nautilus* are presented graphically in Figs. 1 and 2. In Fig. 1 the strontium values for different positions on the venter are plotted directly above those for the corresponding septa marking approximately the same ontogenetic stage, the scale being displaced slightly to avoid confusing overlap. The graphs indicate the overall similarity of the two specimens. Considering only those septal data for which there are corresponding venter data, mean values of the latter are slightly larger in both specimens (that is, about 1,950 p.p.m. compared with 1,850 p.p.m.). We first thought this was probably related to the difference in aragonitic shell layers. Whereas these consist, in the outer wall, of nacreous, spherulitic-prismatic and semi-prismatic layers in similar proportions, the nacreous layer is dominant in the septa<sup>3</sup>. The analyses of venter samples given in Table 2, however, show that strontium values are greater in the nacreous layer than in the outer two layers, at two positions of the outer whorl of *Nautilus B*. There must be therefore independent biochemical control of strontium precipitation in the septal and ventral nacreous layers.

Considering first the septal data, both specimens show a sharp decline from high to low strontium values from the earliest formed to about the eleventh or twelfth septa, after which a phase of comparative stability sets in, followed by a comparatively gentle rise at about the twenty-fifth septa and a final decline in the last two or three septa. Variation in the venter seems in both cases to be largely independent of the septa, with even a tendency towards an inverse relationship, so that peaks in the one group correspond to some extent with troughs in the other, and vice versa. The venter data, especially as shown in Fig. 2, give a clear indication of a slight secular

decline with age of strontium content, on which is superimposed a pronounced cyclicity. Fig. 2 also shows the striking similarity between the two specimens, the only notable exception being a minor peak in *Nautilus A*.

Some limited deductions and tentative suggestions can be made from our results. The variation of strontium content within morphologically different but mineralogically similar shell layers of the same organism, as found in both *Sepia* and *Nautilus*, is of considerable interest. Whereas it has been known for some time that trace element contents may vary within calcareous shells, this has usually been related to the variable development of calcite and aragonite, that is, it is mineralogically determined. Our data, concerned with only one mineral species, indicate that in addition there must be an independent biochemical control, and that crystal parameters only determine the general level of the strontium content. Biochemical determinants are also required to account

Table 2. VARIATION OF STRONTIUM (P.P.M.) IN VARIOUS CARBONATE LAYERS FROM THE VENTER OF *Nautilus B*

	<i>Nautilus B</i> Position 1 Strontium (p.p.m.)	<i>Nautilus B</i> Position 2 Strontium (p.p.m.)
Spherulitic and semi-prismatic layers	1,790 $\pm$ 30	1,870 $\pm$ 40
Nacreous layer	2,040 $\pm$ 40	1,990 $\pm$ 40

Fig. 1. Variation in p.p.m. of strontium in septa/venter increments in *Nautilus A* and *B*.

Fig. 2. Strontium variation in venter samples from *Nautilus A* and *B* plotted as distance from protoconch. Vertical lines indicate the deviation of replicate analyses and include errors due to sample preparation and instrument instability.

for the variations within particular shell layers. These variations are essentially of two kinds. Cyclicity is shown in *Nautilus*. The obvious interpretation, which cannot be proved for the specimens in question, is that these cyclic variations in strontium content correlate with seasonal changes. The only published research known to us, with which our own is directly comparable, is that on *Mytilus* by Dodd<sup>4</sup>, who found that the strontium content of the aragonitic nacreous layer varied inversely with temperature in different seasons. This would suggest that the peaks of Fig. 2 should be correlated with winter seasons, but the fact that septal and venter peaks tend not to coincide renders the problem more complex. Furthermore, Denton and Gilpin-Brown<sup>5</sup> have recently argued, on the basis of varying gas pressures within the chambers of *Nautilus*, that maturity is reached within 1 yr, with septa being secreted at fortnightly intervals, a conclusion which implies a remarkably rapid rate of growth, with weight doubling about every 40 days, and would argue against a seasonal interpretation.

The secular decline of strontium values that is also observable in *Nautilus* could indicate migration during the first few years of life from cooler to warmer waters. Alternatively, it might relate more directly to biochemical changes during ontogeny and have nothing to do with the external environment. A recent paper on oxygen and carbon isotopes in the shell of *Nautilus* is important in this connexion. Eichler and Ristedt<sup>6</sup> found a sharp change in  $\delta^{18}\text{O}$  content of both septa and outer shell. This change, between the seventh and eighth septa, was correlated with temperature change, but with the animal passing the early stages of its life in warmer water. A further point of comparison between our work and that of Eichler and Ristedt is that  $\delta^{18}\text{O}$  values in the septa following the sharp change referred to are more constant than those of the outer shell at a corresponding period of growth. Without more information one should not dismiss the possibility that endogenous factors have played at least some part. This possibility becomes intriguing when it is borne in mind that certain fossil ancestors of *Nautilus* had appre-

ciably higher strontium contents, and that this appears to be a biochemically more primitive condition<sup>7-9</sup>.

### Population Control by Territorial Behaviour in Red Grouse

THERE is uncertainty about the importance of social behaviour in regulating the size of animal populations, as shown by widely different explanations put forward in recent years<sup>1-3</sup>. One difficulty is that firm conclusions on the subject cannot be drawn from correlations derived from simple field observations; and even with birds few experiments have been done in the wild, although the social behaviour of birds is better understood than of most other wild animals. The results of field work are therefore usually open to different interpretations.

The idea that breeding stocks of birds might be limited by their territorial behaviour has been mentioned by so many authors (for review see ref. 2) that it is frequently accepted as an established fact instead of a largely untested idea. Hinde<sup>4</sup>, in his review of the literature on territory in birds, could find no unequivocal support for this idea from field observations. Furthermore, two pioneering experiments<sup>5,6</sup>—still the only important experiments yet published in this field—did not really test this conception. The authors attempted during June–July to eliminate the passerine birds in 16 hectares of forest, and succeeded in reducing them to about 20 per cent of the original level, after which the reduced numbers were maintained by the continued influx of new birds until finally two to three times as many males had been shot as had initially been present. This suggested that the newcomers were surplus birds which had previously been prevented from settling by the presence of the original residents. There was no proof, however, that they were not migrants or territorial birds attracted from somewhere else which might have bred elsewhere if there had been no shooting. In fact, most of the newcomers belonged to one migratory species, and there may have been extra inducement to settle because of abundant food from an outbreak of spruce budworm (*Choristoneura fumiferana*).

To demonstrate that territorial behaviour really limits breeding stocks, it is necessary to show: *a*, that a substantial part of the population consists of surplus non-territorial birds which do not breed; *b*, that these are prevented from holding territory and breeding by the established territory-holders; and *c*, that they are able to take territories and breed, if they are given the chance by the removal of the established birds.

A series of thirteen experiments from 1960 to 1966 has recently been completed, in which red grouse (*Lagopus lagopus scoticus*) were removed from study areas on heather (*Calluna vulgaris*) moorland in north-east Scotland. A useful feature was that the grouse lived on these moorland areas all the year round and did not migrate;

even local movements beyond 5 km were rare<sup>7,8</sup>. In the first three experiments, individual territorial cocks were taken temporarily into captivity and later released. In later experiments, all young or old cocks on certain areas were removed by shooting, and in some experiments the entire stocks of both sexes were shot on areas of up to 52 hectares.

The experiments were preceded by a study of the behaviour of all birds on experimental and control areas, and on ground within 150 m round about. This was backed up by accurate counts<sup>7</sup> of total population size. Red grouse take up their territories in autumn and hold them until the following summer. On each area the grouse population contained both territorial and non-territorial birds, the latter making up about half the autumn population<sup>8</sup>. Territorial birds included cocks which showed territorial behaviour<sup>9</sup>—that is, each cock consistently dominated intruding cocks and kept them out of its individual plot of ground on the heather moor, where it also courted hen grouse—and hens paired up with territorial cocks. Non-territorial cocks and hens did not court, pair up, show territorial behaviour or subsequently breed, and were frequently driven out of the territories by established territorial birds. Because most grouse on and around the study areas were marked with plastic back-tabs for individual recognition, the previous status of most newcomers which appeared on vacant ground was known—a crucial fact for proper interpretation of the experimental results.

The null hypothesis was that there would be no changes in numbers, at least until the breeding season, on control areas and on areas depopulated by shooting between autumn and spring, and that non-territorial birds on or around these areas would also remain as such over the same period. (Effectively, this meant finding whether territorial behaviour limited the size of the breeding stocks.) Neither result was obtained on the experimental areas, while the *status quo* was maintained on the control areas.

Compared with a total of 119 experimental vacancies for territorial birds on five areas between August and June, 111 new birds colonized to take territories by mid-summer. During most of the experiments, most vacancies were filled within 2–3 days and all within 1 week. There were exceptions after experiments in November–December when 2–4 weeks were needed, and in February–March when no replacement occurred until late April. In two experiments in March and one in June, involving nine vacancies in all, there were no replacements until the following autumn. Twelve of the 111 newcomers were of previously unknown status. Fifty-one were juveniles when the August–September experiments were performed (that is, before the time in October when juveniles first took territories in undisturbed populations). Because on average more than half the autumn population later becomes non-territorial and because the mortality rate of first year grouse is the same as in older grouse<sup>7</sup>, more than half these juveniles would probably have become non-territorial if there had been no experiments. Twenty newcomers during experiments after November were previously non-territorial young grouse reared in the previous summer, and four were non-territorial old birds which had lost their former territories before the experiment. Twenty-four newcomers were birds which were occupying territories elsewhere at the time of the experiment and which moved up to 1 km to take territories on the vacant ground.

Two control areas were used, which were roughly the same size as the experimental areas. Out of an initial total of 269 territorial grouse on the control areas before the experiments, there were only three individual changes during the period of removal and colonization on the experimental areas. Two that disappeared were replaced and the third bird moved to colonize vacant ground on the experimental area.

Territorial cocks, the neighbours of which were shot, invariably enlarged their territories before they themselves were shot, which implies that there was some previous pressure against this. Grouse which were previously non-territorial and which took territories on the experimentally vacant ground subsequently bred there, which shows that non-territorial birds are capable of taking territories and breeding, given the chance. On each of the five different experimental areas the breeding stock in the spring after an experimental shooting usually rose to about the same level as before the shooting, irrespective of whether some or all the previous birds were shot, and even though the numbers of grouse on different adjacent areas varied greatly in the same year, and in different years on the same area. Consequently, the ceilings to population size on the different areas were not related to the numbers of birds available on these areas or on adjacent areas. Presumably, these different ceilings were adjusted to some fairly constant environmental feature of each area.

These results show experimentally that territorial behaviour in red grouse sets a limit to the size of the territorial population during the winter months and of the subsequent breeding stock.

### **In vitro Cultivation of the Tapeworm *Hymenolepis nana* from Larva to Adult**

BERNTZEN<sup>1</sup> described an apparatus for the cultivation of *Hymenolepis nana* in continuously circulating medium. His average recovery of live worms from two specified media was 7 per cent and 11 per cent, and this increased to 17 per cent when the temperature of cultivation was raised from 37° to 39° C. In an unspecified number of these worms, fertile eggs were produced by day 12. The advantages and disadvantages of Berntzen's apparatus and media have been discussed by Hopkins<sup>2</sup>.

We were unable to reproduce Berntzen's results and decided to use the medium used by McCaig and Hopkins<sup>3</sup> for the cultivation of *Schistocephalus solidus*. When this medium was dispensed in roller tubes and gassed with 95 per cent nitrogen and 5 per cent carbon dioxide, it supported growth of *H. nana* to 3 mm in length and early strobilation, but no genitalia developed. Supplementation of the medium with various extracts including autoclaved rat liver extracts failed to improve growth significantly, but a cold liver extract prepared using Stoll's technique<sup>4,5</sup> greatly enhanced development.

In a medium of Hanks balanced salt solution, horse serum, 'Oxoid' yeast extract, glucose and rat liver extract, 37 per cent of the cysticercoids grew to sexually mature adults and 50 per cent of these mature worms had fully formed, visibly normal eggs in some of the proglottids. In later experiments, it was found that lamb liver extract was as good as rat liver extract and because lamb liver is more easily available in quantity it was used for all subsequent work. The method of preparation of liver

extract, excystation of the cysticercoid and cultivation was as follows.

Lamb liver was brought from the abattoir in an iced container, chopped into pieces of about 20 g and stored at -15° C. When required it was thawed at 4° C for 48 h. One part by weight of liver was homogenized with four parts by volume of de-ionized water at 4° C keeping the flask surrounded by crushed ice. The brei was adjusted to pH 4.0 with 1 normal hydrochloric acid (approx. 2.5 ml./100 ml. brei), squeezed through muslin and centrifuged at 5,420g for 1 h at 4° C. The supernatant was collected, filtered through a 0.45µ 'Millipore' filter and sterilized by passing through a 0.22µ filter. The sterile extract was stored in aliquots of 5 and 10 ml. at -15° C.

One hundred ml. of medium was prepared by mixing the following solutions in the order stated: (a) 40 ml. Hanks saline; (b) 10,000 units of sodium penicillin G and 10 mg of streptomycin sulphate; (c) 5 ml. of autoclaved 6.5 per cent glucose solution; (d) 10 ml. of a 5 per cent 'Oxoid' yeast extract, filter sterilized; (e) 10 ml. of liver extract; and (f) 30 ml. of horse serum (No. 2, Burroughs Wellcome, London). The pH of the mixture was adjusted to 7.6 by addition of 1.8 ml. of 0.2 normal sodium hydroxide and 3-4 ml. of 1.4 per cent sodium bicarbonate. After mixing, the medium was dispensed in 5 ml. quantities in 125 × 25 mm roller tubes and gassed for 40 sec with 95 per cent nitrogen and 5 per cent carbon dioxide. The culture tubes were immediately closed with 'Esco' RWH grade rubber bungs, placed in a roller drum incubator and rotated (0.15 r.p.m.) for at least 2 h before inoculation with freshly excysted worms.

Infected beetles (*Tribolium confusum*) were dissected in Hanks balanced salt solution (BSS). The freed cysticercoids were washed twice in sterile BSS and thereafter all procedures were carried out at 37° C using sterile solutions containing 100 u of penicillin and 100 µg of streptomycin ('Crystamycin', Glaxo)/ml. The cysticercoids were placed in 1 per cent pepsin (activity 1:2,500; supplied by B.D.H.) in BSS at pH 1.7 (pH adjusted with 0.2 normal hydrochloric acid) for 12-15 min. They were next washed three times with BSS and transferred to trypsin-bile salt solution (0.5 per cent trypsin (83:1, B.D.H.) and 0.3 per cent sodium tauroglycocholate (B.D.H.) in BSS at pH 7.2, pH adjusted with 0.2 normal sodium hydroxide). About 90 per cent of the worms excysted within 8-10 min; these were washed three times in BSS and collected in a Petri dish of 5 cm diameter. From this dish groups of 16-20 excysted worms were transferred to small glass containers, examined under ×12 magnification and pipetted into a culture tube. The tube was gassed a second time with 95 per cent nitrogen and 5 per cent carbon dioxide and returned to the incubator. The pH of the medium 2-3 h after setting up was 7.2 ± 0.2. The medium was changed on days 3, 6, 9, 11 and 13.

The principal results were as follows. Cysticercoids, during 14 days of cultivation, grew to strobilated worms 7-30 mm long, 60-70 per cent had mature genitalia with active sperm and 20-30 per cent produced eggs in some proglottids. Discharged eggs were found in the medium from the tenth day onwards and these eggs and those from proglottids have been fed to the intermediate host where they developed into normal infective cysticercoids.

Work has started to determine the conditions under which the liver extract is active. It is known to lose its activity gradually after storage for 4 weeks at 4° C, but it retains full activity for at least 4 months at -15° C. Heating the liver extract for 6 min at 53° C does not inactivate it (compare Sayre *et al.*<sup>6</sup>). A precipitate forms within 2 weeks of storage at 4° C which must be resuspended; if this is separated by centrifugation the supernatant is inactive. When the complete medium is prepared a precipitate forms at the time of mixing (associated with changing the pH of the liver extract from about 4 to neutral) or shortly after rotating in the roller tubes. The formation of this encrusting precipitate is important

and is in some way associated with the ability of the worms to grow and mature (compare Smyth *et al.*<sup>7</sup>).

### Infertility in Mice and Guinea-pigs induced by Feeding with a Fungal Pathogen isolated from Leaves of *Romulea rosea* (Linn.) Eckl.

IN areas of low soil fertility, in the State of Victoria, *Romulea rosea*, known locally as Onion Grass, is a fairly common constituent of pastures. The seeds and corms germinate after the first autumn rains; and in some circumstances these plants provide valuable autumn feed for stock.

Evidence has accumulated during the past 20 yr to show, however, that in certain seasons a disease of sheep is associated with the consumption of pasture containing a high percentage of *R. rosea*. Gorrie<sup>1</sup> clearly defined the symptoms of this disease syndrome which includes infertility, abortion and paralysis; and he named the disease "romulosis".

During the late autumn and early winter of 1965 "romulosis" was reported from several areas within a radius of about 100 miles of Melbourne. All toxic pastures inspected were *Romulea* dominant; furthermore, a leaf spot condition was a conspicuous feature of these plants.

Initially, discrete Chestnut brown<sup>2</sup> spots, about 1-2 mm in diameter, developed in the leaf tissue; later individual spots coalesced and finally complete necrosis occurred, usually extending from the tip downwards.

*Helminthosporium biseptatum* Sacc. and Roum, was isolated from leaves of *R. rosea* collected from very toxic pasture, near Seymour, about 60 miles north-east of Melbourne.

Pathogenicity of the fungus was established by inoculation of healthy seedling plants of *R. rosea* with a pure culture of the isolant.

The inoculation technique, which was carried out in a heated glasshouse, involved atomizing leaves with an aqueous suspension of conidia. Incipient spotting of the leaves appeared after 10-11 days and typical lesions from which *H. biseptatum* was re-isolated developed after 21 days.

Infertility in sheep is an important symptom in the "romulosis" syndrome, and so preliminary feeding trials were conducted to determine whether the *Romulea* leaf-spot fungus had an effect on the breeding efficiency of laboratory animals, such as mice and guinea-pigs.

Free feeding methods were used, and it was essential that the culture medium should provide food acceptable to the animals, particularly the guinea-pigs. Oatmeal was selected after testing the growth of the fungus on several natural plant media. The medium was prepared by mixing 40 g of oatmeal + 50 ml. of water in a 250 ml. Erlenmeyer flask and autoclaving on 3 successive days, for 20 min at 15 lb. pressure.

The fungus was incubated at 21°C until the oatmeal was thoroughly permeated by the mycelium—11 to 12 weeks.

The oatmeal fungal culture was then incorporated in the standard mash used for feeding to laboratory animals (experimental diet), and an equivalent amount of oatmeal medium was added to the standard mash to provide the control diet.

The experimental diet for mice contained 5 per cent fungal culture; guinea-pigs, however, rejected this diet and the fungal additive was reduced to 2.5 per cent.

The feeding trials were designed to comprise four groups: (1) males and females fed experimental diet; (2) males fed experimental diet and females fed control diet; (3) males fed control diet and females fed experimental diet; (4) males and females fed control diet.

In the mouse trial, there were twenty-four females in each group and one male was mated to two females. Mating commenced on day 35 of feeding and was allowed to continue for 16 days. At the end of the mating period the males were killed and examined.

In the guinea-pig trial there were eight females in each group and they were mated at the rate of one male to four females. Mating was commenced on day 21 of feeding and was continued for 21 days after which the males were killed and examined.

Each feeding trial was terminated when all pregnant females had produced their litters. All females and litters were then killed and examined.

The results of these feeding trials are shown in Table 1.

Animal	Group	Control diet	Exper. diet	Pregnant	Not pregnant	No. females in group
Mouse	1		♂ ♀	12	12	24
	2	♀	♂	19	5	24
	3	♂	♀	12	12	24
	4	♂ ♀		18	6	24
Guinea-pig	1		♂ ♀	2	6	8
	2	♀	♂	5	3	8
	3	♂	♀	7	1	8
	4	♂ ♀		8	0	8

Statistical analysis of the number of pregnancies in each group indicates that the fungus caused a reduction in the breeding efficiency of the female mice, significant at 2 per cent and almost at the 1 per cent level.

With guinea-pigs, on the other hand, females were not affected but ingestion of the fungus caused a reduction in the breeding efficiency of the males which was significant at the 1 per cent level.

Post-mortem examination of the experimental animals did not disclose any macroscopic differences between feeding groups; and the results of histological examinations of selected organs have yet to be evaluated.

In certain conditions the *Romulea* leaf spot fungus seems to adversely affect animal reproduction, but the nature of its action has yet to be investigated. The possibility that an oestrogen or related compound may be involved should not be overlooked in view of the finding<sup>3</sup> that two foliar pathogens (*Pseudopeziza medicaginis* and *Leptosphaerulina briosiana*) significantly increased the coumestrol content of alfalfa.

We thank Mr R. Jardine, of the Victorian Department of Agriculture, for the statistical analysis of the feeding trials. We also thank Mrs Brush, of the Veterinary Research Institute, Melbourne, for technical assistance, and Dr Ellis, of the Commonwealth Mycological Institute, Kew, for identifying the fungus.

### Effect of Carbohydrates on the Symbiotic Growth of Planktonic Blue-Green Algae with Bacteria

PHOSPHORUS and nitrogen have been suggested to be limiting agents in the unwanted growth of Cyanophyta. Removal of phosphorus from sewage effluents is being considered as the preferred method to control eutrophication. The significance of organic matter in lake water has been largely disregarded, although carbonaceous material is always found in productive lakes, for example, from 22 mg to 99 mg/l. of dissolved organic matter in the Great Lakes<sup>1</sup>. Massive growths of blue-green algae have been documented before the use of industrial phosphates, and they probably occurred always after a heavy influx of organic matter. Maximum growth of phytoplankton does not require high concentrations of phosphorus. As little as 0.02 mg of phosphorus/l. in natural lake water may sustain it<sup>2</sup>. Additional phosphorus alone does not increase growth because algal growth will depend on the presence and availability of not less than fifteen essential elements<sup>3</sup>.

Planktonic Cyanophyta are always associated with bacteria, and I have found that abundant algal growth results from a symbiotic relationship within their systems. In particular, the results reported here suggest that the bacteria assimilate added carbonaceous material and produce carbon dioxide which accelerates algal photosynthesis. The addition of a source of carbon also apparently delays the bacterial assimilation of organic chelating agents which are necessary if nutritional elements are to remain accessible at a high pH. Reports<sup>4-10</sup> are consistent with various findings and, as a whole, support my conclusions.

I have grown the algae in Zehnder and Gorham's medium No. 11 (ref. 11) which contains, among other minerals, 6.9 mg of phosphorus/l., 81.7 mg of nitrogen/l. and only 6.7 mg of carbon/l. Half of the heavily inoculated growth medium was mixed with an aqueous solution of sucrose, the other half (the control) received an identical volume of distilled water. Quantities of 50 ml. of the two cultures were placed in 250 ml. Erlenmeyer flasks which were loosely capped with aluminium foil. The flasks were exposed to fluorescent illumination of 50 ft. candles (540 lux) in a 16-8 h cycle of light and dark at 22° C. The

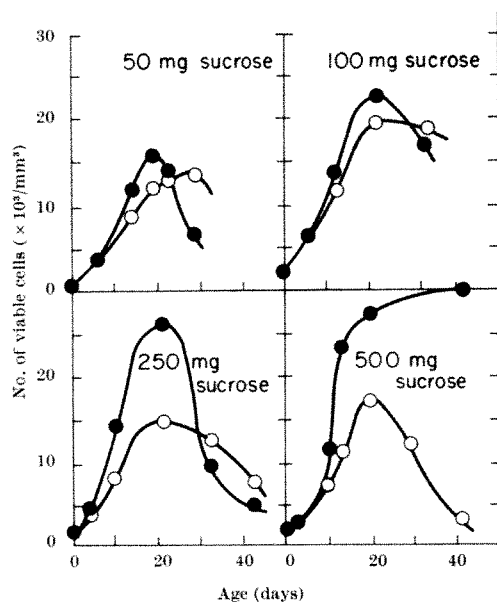

Fig. 1. Effect of added sucrose (mg/l.) on *Microcystis aeruginosa* Kütz. Wisc. 1036 cultures containing bacteria. Starting concentrations were: 6.2 mg of phosphorus/l. as orthophosphate, 73.5 mg of nitrogen/l. as nitrate. Light was 50 ft.-candles (540 lux) at 22° C. Numbers of viable cells plotted versus age of cultures; ●—● sucrose cultures, ○—○ sucrose free control cultures.

Fig. 2. Effect of added sucrose on cultures containing bacteria, EAWAG 18, Clone 51 (left) and on pure cultures of *Oscillatoria rubescens* DC, EAWAG 19, Clone 51 R (right). Starting concentrations: 5.3 mg of phosphorus/l., 80.6 mg of nitrogen/l., and 500 mg of sucrose/l. Light was 50 ft.-candles (540 lux) at 22° C. Total lengths of algal filaments and chemical oxygen demand of membrane filtrates and of biomass plotted versus age of cultures.

Legend:  
 Filament lengths: ●—● (sucrose-containing), ○—○ (sucrose free control)  
 Chemical oxygen demand of filtrates: ●—● (sucrose-containing), ○—○ (sucrose free control)  
 Chemical oxygen demand of biomass: ■—■ (sucrose-containing), □—□ (sucrose free control)

pH of the cultures ranged from 8.9 at inoculation to 10.5 when growth was at a maximum, and it decreased when bacterial growth and cell lysis prevailed. For analysis, cells appearing viable on the basis of colour and refraction were counted in a haemocytometer, or the lengths of filaments were measured. Chemical oxygen demand was determined on the total culture and on the membrane filtrate; the difference was taken as the biomass.

The unialgal cultures of Cyanophyta containing bacteria which were used are shown in Fig. 1 and Table 3. Professor O. Jaag and Miss B. Egli of the Swiss Federal Institute of Technology provided axenic cultures<sup>12</sup> and bacteria-containing cultures of *Oscillatoria rubescens* (Fig. 2).

In four separate experiments with bacteria-containing *Microcystis aeruginosa* systems at different concentrations of sucrose (Fig. 1), the cultures containing sucrose showed greater growth than the controls. Maximum growth was often achieved within 3 weeks, and then the number of viable cells declined simultaneously with their discoloration. This decline seemed to coincide with the disappearance of the added carbonaceous matter and often was more rapid in the cultures fed sucrose.

The following observations suggest a protective function of the added source of carbon against bacterial degradation of the metal chelates. The membrane filtrate of declining control cultures still contained 1.0 mg of phosphorus/l. and 37 mg of nitrogen/l. The cultures could only be revived by the addition of a solution of ferric citrate, the minor elements, ethylenediamine tetraacetic acid (EDTA), and citric acid in the original concentrations, increasing the carbon content in the final culture by only 2.2 mg of carbon/l. The addition of the chelated metals slowly restored the blue-green colour of the algae, and growth resumed. Deterioration of the cultures soon started again, apparently as a result of bacterial assimilation of the insignificant amount of added organic chelating agents (Table 1). The large number of bacterial cells in deteriorating cultures fed sucrose prevented a revival because the added chelating agents were assimilated too rapidly. The blue-green colour was restored, but growth did not resume and the cultures started to deteriorate further 2 days later.

The effect of an added source of carbon on algal growth was duplicated by raising the concentration of carbon dioxide in the atmosphere (Table 2). Table 3 gives the

results for other alga-bacteria systems fed 500 mg of sucrose/l. in similar conditions.

Axenic cultures and cultures of *Oscillatoria rubescens* containing bacteria, a strict photolithoautotroph<sup>12</sup>, were grown in the presence or absence of sucrose. Sucrose was of no value to the axenic alga, but it stimulated the growth of the association of bacteria and alga (Fig. 2).

Work in progress indicates that many sugars and polyhydric alcohols, glucuronate, citrate and starch give results similar to sucrose. Also, using closed containers at decreasing ratios of enclosed air and algal culture volumes with proper illumination, *Microcystis* and its associated bacteria may grow in low concentrations of oxygen without an atmospheric source of carbon dioxide if enough organic matter is available.

## Action Potentials in the Reproductive System of Plants

DURING the process of sex differentiation, male and female metabolic systems develop in the flower. Their unification at pollination creates a single system with a metabolism of extremely high intensity<sup>1-3</sup>. Electrophysiology may show when the pollen starts to affect the pistil tissue and give information about the nature of the primary reactions induced.

We used *Incarvillea grandiflora* and *I. delavayi* species of an entomophilous genus of the Bignoniaceae. The bilobate stigmas are sensitive to mechanical pressure or irrigation. *Lilium martagon*, a plant with an insensitive stigma, was used as the control.

Fig. 1 shows the scheme for attaching measuring devices to the pistil of *Incarvillea*. A microelectrode of a d.c. amplifier (DCA<sub>1</sub>) was inserted into the top of the stigma lobe, and the electrode of the second amplifier (DCA<sub>2</sub>) was inserted into the junction of the lobes, and the electrode of the third d.c. amplifier (DCA<sub>3</sub>) into the tissue of the style. Microthermistors of the Karmanov type<sup>4</sup> were applied to the tissues of the lower part of the lobe or to the style to record the temperature and possible flow of water. An electronic amplifier and a potentiometer were used to record potentials. The diameter of the micropipette end of the glass electrodes was less than 1–2  $\mu$ . The internal resistance of electrodes was measured before and after the experiments. Pipettes were made of 'Pyrex' and filled with 3.0 molar potassium chloride. Calomel electrodes were used as pickups. Ovaries were placed into a chamber of organic glass and the pickup of oxygen was recorded by an electrochemical method<sup>5,6</sup>.

Electrophysiological investigations of stigmas of *Incarvillea* and simultaneous recording of their movements with a kymograph showed that action potential (AP<sub>1</sub>) appeared in response to mechanical irritation of the top of the lobe with a soft brush in about 0.2 sec (Fig. 2a). AP<sub>1</sub> spread to the base of the stigma with a velocity of 1.8 cm/sec, and in 0.8–1.0 sec it reached the point where they joined, that is, the tissues which give rise to the motor reaction of stigma. The lobes started to move 0.1 sec after this and the stigma closed in 6–10 sec.

If mechanical irritation was not followed by pollination the stigma began to open some minutes after closing and was fully open and ready for the next irritation in 17–22 min. It is interesting that the action potential of mechanical irritation (AP<sub>1</sub>) reached only as far as the junction of stigma lobes and could not penetrate into the style because of the physiological non-conductivity block in it.

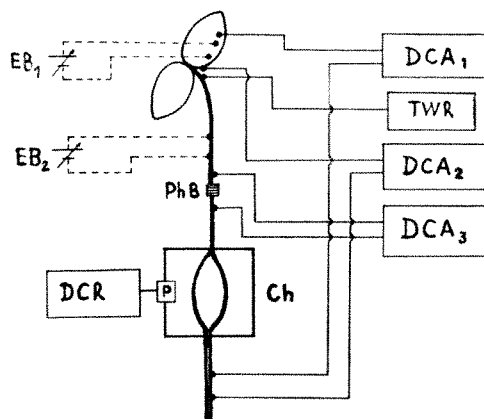

Fig. 1. Scheme for measuring potentials and intensity of respiration in the flowers of *Incarvillea*. DCA<sub>1</sub>–DCA<sub>3</sub>, d.c. amplifiers; TWR, recorder registering temperature and water flow along the tissues; P, electrochemical pickup (Clark microelectrode) for registration of partial oxygen pressure; DCR, d.c. recorder; Ch, chamber for measuring of respiration intensity; EB<sub>1</sub>, EB<sub>2</sub>, electrotonic blocks; PhB, physiological block.

If pollen was placed on the stigma lobes with caution and there was no mechanical irritation,  $AP_1$  was not aroused and the stigma did not close in the first seconds; closing started only 3–17 min after application of pollen. It was preceded by polarization of rest potentials in the column by 30–40 mV (Fig. 2b), after which the second action potential ( $AP_2$ ) with the amplitude of 80–90 mV appeared in the stigma (Fig. 2c) and caused it to close.

A negative rest potential caused the non-conductivity block in the column to disappear and  $AP_2$  spread down the style at a rate of about 2.9 cm/sec. It was recorded by the electrodes of the third d.c. amplifier (DCA<sub>3</sub>). Primary and reversible stimulation of the oxygen consumption up to 5–11 per cent was recorded in ovary tissue 60–90 sec after  $AP_2$  reached them (Fig. 2d).

In 4–16 min, respiration intensity returned to the initial level and then increased slowly and sometimes irregularly and reached a maximum in 10–36 min, depending on the maturity of the stigma. In the case of simultaneous mechanical irritation and pollination, reciprocal reactions appeared in succession. Generation of action potential ( $AP_1$ ) and motor reaction of stigmas were observed first and they were followed by negatization of the rest potential, and generation and spreading of  $AP_2$  down the column. Finally, stimulation of oxygen consumption by the ovary was observed. Amplitude, velocity of spreading and the forms of  $AP_1$  and  $AP_2$  were analogous to those of plants which have motor reactions<sup>7–11</sup>.

Spreading of  $AP_1$  and  $AP_2$  can be stopped by blocking their path with electronic and physiological (solution of 2,4-dinitrophenol) "blocks". Then the primary reciprocal reaction expressed as motion of the stigma and stimulation of respiration at the ovary are not observed when pollen is applied to the stigma lobes. These processes recommence after removal of the electrotonic blocks.

The stigma of *Lilium martagon* has no motor reaction and does not generate  $AP_1$  (Fig. 2a<sub>1</sub>). The rest potential

generation and spreading of  $AP_2$  as well as stimulation of the respiration of the ovary become negative after pollination (Figs. 2b<sub>1</sub>–2d<sub>1</sub>). Thus the electrophysiological response of pistils to pollen seems to be common for *Incarvillea*, *Lilium* and *Zea mays*<sup>12</sup>. Differences are concerned only with the specific stigma sensitivity of *Incarvillea*.

Thus there is a relation with time of the generation of spreading potentials  $AP_1$  and  $AP_2$  with the reciprocal physiological reaction some distance from the place of irritation and also with the absence of such a reaction when spreading potentials are blocked. This supports the function of  $AP_1$  and  $AP_2$  as a signal.

$AP_1$  appears as a result of pressure or mechanical irritation of the sensory cells of the stigma and activates motor cells at the junction of the stigma lobes which cause the stigma to close.  $AP_1$  is localized in the stigma.

$AP_2$  appears in the stigma first as a result of chemical action of the pollen secretion (it is interesting that rest potentials became negative and  $AP_2$  developed when solutions of 2,4-D and IAA were applied to the stigma).  $AP_2$  spreads down the column and signals to the ovary that pollen is on the stigma. The ovary responds to this signal by changing its metabolism, which is probably the beginning of the preparation of the female reproductive area for fertilization. This is usually expressed in an increase of respiration. In other investigations intensification of the flow of phosphorus-32 to the ovaries has been found soon after pollination<sup>1,3</sup> and restoration of Feulgen reaction in the egg cells before pollen tubes reach the ovaries has also been found<sup>13</sup>. The physiological significance of such reactions is most clearly expressed in some orchids and trees in which the development of the embryo sac and the ovules begins only after pollination and goes on for many weeks and months simultaneously with the growth of pollen tubes in conductive tissues of the pistil.

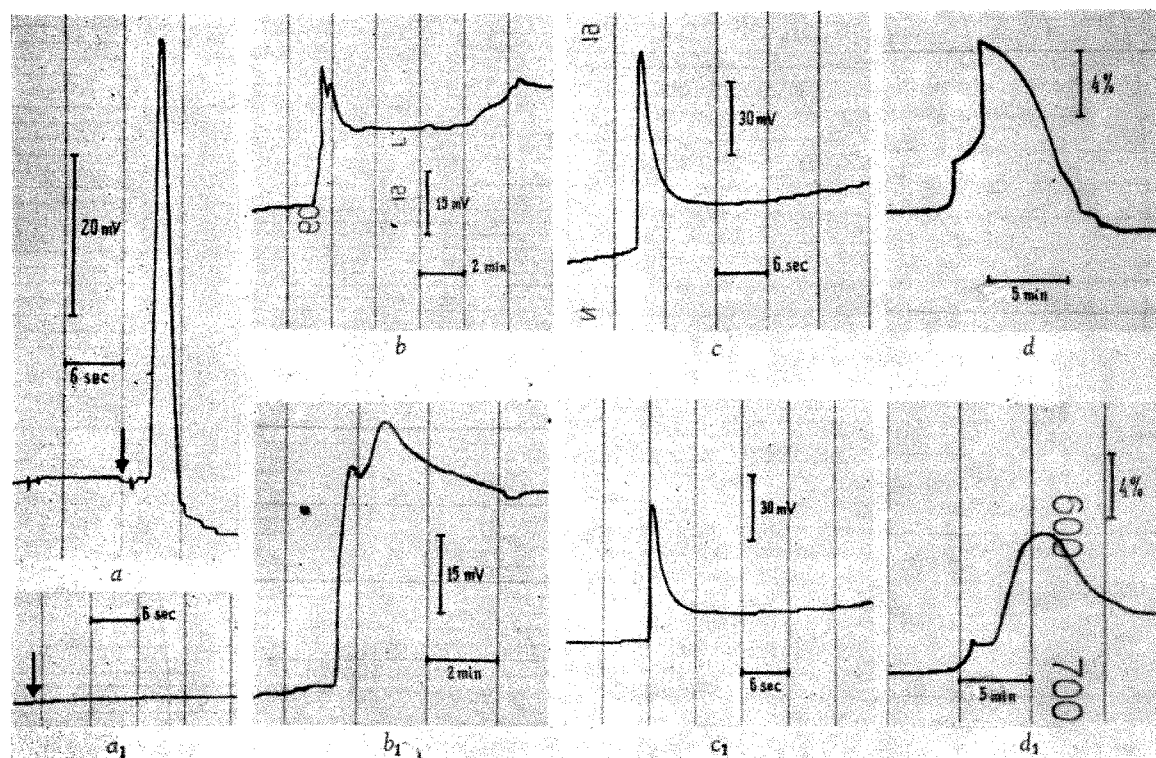

Fig. 2. Potentiograms of potential and oxygen consumption by pistils. Upper row: pistils of *Incarvillea*: (a)  $AP_1$  action potential in stigma in response to mechanical irritation; (b) negatization of rest potential in style; (c)  $AP_2$  action potential in response to application of pollen; (d) primary reversible stimulation of oxygen consumption under the influence of  $AP_2$ . Lower row: pistils of *Lilium*: (a<sub>1</sub>) absence of  $AP_1$  in response to mechanical irritation; (b<sub>1</sub>) negatization of rest potential; (c<sub>1</sub>)  $AP_2$  action potential in response to pollen application; (d<sub>1</sub>) primary reversible stimulation of oxygen consumption under the influence of  $AP_2$ . Arrows: the beginning of mechanical irritation.

Our data may explain the observations<sup>14</sup> that the stigmas of sensitive plants may close because of the action of an electric current (which is analogous to our AP<sub>1</sub> action) or that the cutting and maceration of the unpollinated style have no immediate effect on the closing of the stigma (in our opinion, because of its non-conductivity).

The ability of tissues of the column of *Incarvillea* to conduct one action potential and to block the other shows how useful reciprocal reactions during pollination have evolved. Ovaries are protected from the necessity to respond to an incidental mechanical irritation of stigmas, including irritation caused by insects bringing no pollen.

### Simple Immunological Method for the Diagnosis of Pregnancy in Mares

THE diagnosis of pregnancy in women has been routinely effected by utilizing the reaction in which human chorionic gonadotrophin (HCG) inhibits the agglutination of HGC-coated red blood cells<sup>1,2</sup> or latex particles<sup>3</sup>. The same method was then used for the assay of pregnant mare serum gonadotrophin (PMSG)<sup>4</sup> and it was shown that PMSG in the sera of pregnant mares was detectable after about day 44 of pregnancy, increased to a maximum around the seventieth day as reported earlier<sup>5</sup> and had decreased to small concentrations by day 120. Similar experiments done by other workers seem to have been less successful<sup>6-8</sup> chiefly because mare sera cause variable degrees of non-specific agglutination even after extraction with acetone or ethanol.

It has also been shown that there is in PMS during the relevant period of gestation an  $\alpha_2$ -globulin soluble in perchloric acid which precipitates with rabbit serum anti-PMSG that has been absorbed with non-pregnant mare serum (NMS)<sup>7-9</sup>. This could provide a method for pregnancy diagnosis, but King<sup>10</sup> had difficulty in producing rabbit antisera to PMSG. He found that some antisera failed to precipitate with his preparations of PMSG after absorption with NMS; others precipitated with PMS but the amount of precipitate did not correlate with the PMSG as measured by its biological activity, and the precipitin reactions were too feeble to be used for pregnancy diagnosis.

It seemed reasonable to suppose that hormones such as PMSG would not be very antigenic in other mammalian species and, because all the existing preparations contained other proteins, it would not be easy to make the antisera specific for the hormone by absorbing them with NMS. On the other hand, injection of PMSG into birds

Fig. 1. Reactions in agar gel of turkey serum anti-PMSG (absorbed with an equal volume of NMS) with (1) PMS (day 63 of pregnancy), (2) PMSG (1,000 IU/ml., 'Organon'), (3) Endometrial cup secretion and (4) PMSG (1,000 IU/ml., Leo Pharmaceuticals). 1.5 per cent agar containing 1.5 molar sodium chloride, 0.04 molar phosphate buffer pH 7.0, 0.01 molar sodium azide.

Fig. 2. Reactions of absorbed turkey serum anti-PMSG with NMS to which has been added PMSG to the concentrations (in IU/ml.) shown. This polygon-plate method permits detection of PMSG at concentrations as low as 2.5 IU/ml.

might be expected to give antisera in which the ratio of anti-PMSG to antibodies to impurity antigens would be much greater than was found with mammals.

Accordingly, commercially available PMSG and PMSG derived from endometrial cup secretion (DEAE-2 and upper phase fractions prepared by Dr W. R. Butt<sup>11</sup>) were mixed with Freund's complete adjuvant and injected, subcutaneously into turkeys. After 2 months their sera contained useful amounts of precipitating antibodies and the antisera have improved several hundred-fold in the intervening 18 months. The commercial PMSG (presumably prepared from PMS) was more satisfactory than that derived from endometrial cup secretion in that the latter

Fig. 3. Pregnancy diagnosis using the polygon-plate method. In each set of wells alternate peripheral wells contained sera obtained from a pregnant mare on days 34, 40, 48, 55, 63, 76, 83, and 90. PMSG was clearly present on day 48 and later.

caused the production of a greater proportion of antibodies to impurity antigens.

Absorption of the antisera (twenty volumes) with NMS (one volume) removed antibodies to all but two components of PMS. Absorption using equal volumes of antisera and NMS was necessary to remove antibodies to the second component. Fig. 1 shows that only one precipitation line is formed with PMS, commercial PMSG and endometrial cup secretion, the reaction being one of complete identity throughout.

At very low concentrations of the antigen the intensity of the precipitation line in Ouchterlony plates is too low for it to be detected either before or after staining with amido schwarz. It is, however, possible to detect as little as 2.5 IU of PMSG/ml. of solution by the use of the polygon-plate method of analysis<sup>12</sup>. Fig. 2 shows an experiment in which alternate peripheral wells have been filled with NMS to which PMSG has been added to give a final concentration of 400 IU of PMSG/ml. These give rise to strong

precipitation lines with the absorbed antiserum in the central wells. The remaining peripheral wells have been filled with NMS having 25, 12.5, 5 or 2.5 IU PMSG/ml. Clearly the presence of antigen at a concentration of 25 IU/ml. in the intervening wells has caused a marked deviation of the principal lines. At 2.5 IU/ml. there is almost no deviation of the lines, but there is just sufficient to be detectable.

This technique has been applied to the detection of PMSG in mare sera for the purposes of pregnancy diagnosis. Fig. 3 shows the results obtained with sera from a typical pregnant mare. In this instance the presence of PMSG is very evident at day 49 of pregnancy and its concentration is maximal between 63 and 76 days. In one case PMSG could just be detected as early as day 39. Of fifteen mares in which pregnancy was later confirmed the presence of PMSG in the serum was detected in all before day 50. When using the fully absorbed antiserum no false positives have so far been obtained with sera from stallions and non-pregnant mares.

This method is extremely simple in practice. The preparation of the agar gel-plates was similar to one described elsewhere<sup>13</sup> except that the solvent contained 1.5 molar sodium chloride instead of the usual 0.15 molar sodium chloride. This is necessary because turkey antisera precipitate maximally with the antigens at the higher salt concentration.

In general the detection of antigen by the method of inhibition of haemagglutination (HI test) is more sensitive than the precipitin test and an attempt was made to apply it in this case in the hope of detecting pregnancy a few days earlier. But at present the HI test is slightly less sensitive than the precipitin test and much less reliable. Probably very little can be gained by increasing the sensitivity of the test below the level of 2.5 IU PMSG/ml. of serum from the point of view of pregnancy diagnosis, but it would be useful for fundamental research on the production of PMSG by the endometrial cup.

Subsequently turkeys have been used for the production of antisera to a number of other mammalian hormones with much success. Samples of the absorbed and freeze-dried turkey serum anti-PMSG are available on application.

## GENETICS

### Induction of Genetically Recombinant Chromosomes in the Absence of Induced Mutation

GENETICALLY recombinant chromosomes can be induced (at a low frequency) in the *Drosophila melanogaster* male, although crossing-over does not usually occur in the male. The agents which have been shown to induce crossing-over are all mutagens (for example, formaldehyde<sup>1-3</sup>, diethyl sulphate<sup>4</sup>, nitrogen mustard<sup>5</sup>, dihydroxy-

dimethylperoxide<sup>6</sup>, X-rays<sup>7</sup> and  $\gamma$ -rays<sup>8</sup>). It is therefore difficult in general to exclude the loss of a coupled genetic marker by mutation or by chromosomal deletion over one (or more) of the genetic markers. Usually, the latter event is operationally defined by lethality of the homozygote for the apparently recombinant chromosome, although the simultaneous presence of an independent recessive lethal mutation cannot necessarily be ruled out.

A study of induced crossing-over should thus ideally be carried out with an agent which is either not a mutagen, or else a mutagen which is not mutagenic under readily definable conditions: the latter situation is fulfilled only for the case where formaldehyde is administered by the larval feeding method in *Drosophila* larvae. In fact, formaldehyde is the only mutagen for which a direct attempt has been made to study the mechanism of action of a mutagen in a multicellular organism, and for which there is direct experimental evidence for the mode of action.

The present paper reports on the induction of genetical recombination by formaldehyde in the *Drosophila* male under conditions where it is mutagenic, and under conditions where it is not mutagenic.

Mutations can be induced in *Drosophila melanogaster* by administering formaldehyde by two different methods: injection of formaldehyde into the abdominal cavity of the adult male, or the addition of formaldehyde to the culture medium on which larvae are allowed to develop. Results obtained by these two methods of administration suggest that formaldehyde is capable of producing mutations by two qualitatively different mechanisms.

Following adult injection, it has been suggested that formaldehyde exerts its mutagenic effect by the formation *in vivo* of an organic peroxide, dihydroxydimethylperoxide<sup>9</sup>: when injected into the adult male, this peroxide behaves as a mutagen with much the same behaviour as formaldehyde in preferentially affecting mature and almost mature spermatozoa, and spermatogonial germ cell stages<sup>9</sup>.

By the larval feeding method, it has been shown that formaldehyde exhibits no mutagenic activity towards *Drosophila melanogaster* larvae unless a source of adenylic acid (or adenosine) is present in the treatment medium<sup>10</sup>. Adenylic acid may be present either as the free monoribonucleotide (-3' or -5' isomers) or bound in the (yeast) RNA polynucleotide<sup>11</sup>, but its presence in the treatment medium is essential for the mediation of the mutagenic activity of formaldehyde (as measured by the frequency of sex-linked and second chromosome recessive lethal mutations). Because the chemical binding of formaldehyde by RNA and its individual constituent nucleotides appears to be a specific function of the amino groups of the bases, reaction(s) *in vitro* (in the treatment medium) at the extranuclear 6-amino group of adenylic acid (or adenosine) has been postulated as forming an essential metabolite(s) concerned in the mediation of the mutagenic activity of formaldehyde<sup>10</sup>. This hypothesis is supported by the observation<sup>12</sup> that the replacement of the 6-amino-group of adenylic acid (or adenosine) by a hydroxyl group, as in inosinic acid (or inosine), completely removes the ability of these compounds to mediate the mutagenic activity of formaldehyde, despite the apparently similar utilization of both these adenine and hypoxanthine derivatives by *Drosophila* larvae. Reaction of different concentrations of formaldehyde with a standard concentration of adenylic acid (adenosine-5'-phosphate) before addition to the treatment medium has shown that the monohydroxymethylation of adenosine-5'-phosphate by formaldehyde produces an effective mutagenic derivative, whereas the dihydroxymethylated derivative of adenosine-5'-phosphate does not appear to be mutagenic<sup>13</sup>. Similar experiments where yeast RNA was reacted with formaldehyde, and dialysed free of unbound formaldehyde, have shown that here, too, the monohydroxymethylation reaction of formaldehyde with RNA produces an effective mutagenic derivative(s)<sup>13</sup>.

Because free formaldehyde is not present in the treatment medium in the formaldehyde-treated RNA experiments, it would appear that the monohydroxymethylation reaction of formaldehyde with RNA (and adenylic acid) is in itself both a necessary and sufficient condition for the mediation of the mutagenic activity of formaldehyde. Recent experiments, as yet unpublished, have further shown that whereas adenosine-5'-phosphate is a mediator of formaldehyde-induced mutagenesis, its deoxyribose derivative (deoxyadenosine-5'-phosphate) is not effective: this result suggests that formaldehyde-induced mutagenesis is mediated by way of RNA synthesis. Observations on the patterns of mutational response of larval germ cells (primary spermatocytes, and spermatogonia) indicate that the sensitive period for the activity of formaldehyde is restricted to the auxocyte stage in primary spermatocyte development<sup>14</sup>, that is, the protracted growth stage which precedes meiosis in the larval testis: spermatogonia are not affected, unlike the situation in the adult testis when free formaldehyde is injected into the adult male. Free formaldehyde is not found to be mutagenic when injected into *Drosophila* larvae<sup>15</sup>.

On the basis of these observations, I decided to use the *Drosophila* larval feeding method to test previously reported findings<sup>2,3</sup> (using this method), that formaldehyde is capable of inducing genetically recombinant chromosomes in the *Drosophila* male. Because it is known that the presence of a source of adenylic acid in the larval treatment medium is essential for the mediation of the mutagenic activity of formaldehyde, experiments on the induction of recombinant chromosomes from the *Drosophila* male were carried out under conditions where formaldehyde is mutagenic (adenylic acid present), and under conditions where formaldehyde is not mutagenic (adenylic acid replaced by inosinic acid); the frequencies of sex linked recessive lethal mutations were determined to verify that the required conditions were attained. Larvae which were heterozygous for the coupled second chromosome markers, dumpy wing (*dp*), cinnabar eyes

(*cn*), and brown eyes (*bw*) ( $\frac{+dp+cn+bw}{dp\ cn\ bw}$ ) were treated

for the entire larval life, at a density of 100 larvae/25 ml. of medium, on a formaldehyde-containing ( $1.4 \times 10^{-2}$  molar) chemically defined and axenic medium<sup>16</sup> which contained no source of purines or pyrimidines other than the ones indicated. Because the *Drosophila* Oregon-K wild type stock used to construct the hybrid has a partial dietary requirement for cytidine, however, 0.025 per cent cytidine-3'-phosphate was always present in the treatment media. Males hatching from each treatment medium (and the control) were divided into two batches; males from one batch were individually mated to two dumpy, cinnabar, brown females for 3 days for the detection of recombinant chromosomes, and males from the other batch were individually mated to two Muller-5 females for 3 days for the estimation of sex-linked recessive lethal mutations<sup>17</sup>.

Table 1 illustrates the results obtained when larvae were cultured on the chemically defined medium (plus adenylic acid, or inosinic acid) in the absence of formaldehyde (data combined for the control), on the medium containing formaldehyde and adenylic acid (0.1 per cent), and on the medium containing formaldehyde and inosinic acid (0.1 per cent). Recombinant chromosomes are seen to be induced by formaldehyde both under conditions where formaldehyde is mutagenic (formaldehyde + adenylic acid) and under conditions where formaldehyde is not mutagenic (formaldehyde + inosinic acid): no recombinant chromosomes occur in the progenies of the control males. All tested recombinants were found to be viable when homozygous. Some evidence for a differential effect on one region of the chromosome is suggested by the greater frequency of the cinnabar, brown recombinants compared with the dumpy, cinnabar re-

		ADENYLIC ACID		Total offspring (n) and recombinants (r)		Percent

Per cent lethals, percentage of sex-linked recessive lethal mutations. rA5'-P, Adenine ribonucleoside-5'-phosphate (adenylic acid). rH5'-P, Hypoxanthine ribonucleoside-5'-phosphate (inosinic acid).

The present technique of sampling one 3-day brood from males treated with formaldehyde from the beginning of larval life recovers larval germ cells which were present predominantly as primary spermatocytes at the time of treatment; the primary spermatocyte has been shown to be the germ cell stage to which the mutagenic activity of

THOMAS ALDERSON

<sup>17</sup> Auerbach, C., in *Mutation, Part I, Methods* (Oliver and Boyd, 1962).

BIOCHEMICAL studies have shown that aryl sulphatase is concentrated in lysosomal fractions of liver<sup>1,2</sup>. This can now be confirmed cytochemically because hydrolytic enzymes other than acid phosphatase can be identified at the ultrastructural level. Histochemical methods of producing electron-dense enzyme reaction product at the sites of localization of *E*.600-resistant esterase<sup>3</sup>, and aryl sulphatase<sup>3</sup>, will provide important new information on the rapidly enlarging concept of lysosomes<sup>4,5</sup>. de Duve<sup>6</sup> stressed the importance of developing these cytochemical

methods for a wide spectrum of lysosomal enzymes. It is to be hoped that these may to some extent augment acid phosphatase as lysosomal markers.

Utilizing *p*-nitrocatechol sulphate as a substrate<sup>7</sup> buffered at pH 5.2, and barium chloride as a capture reagent as suggested by Hugon and Borgers<sup>8</sup>, the ultrastructural localization of aryl sulphatase in Swiss albino mouse kidney and liver has been investigated. Frozen sections (50 $\mu$ ) from tissue blocks fixed in 3 per cent buffered glutaraldehyde were incubated at 37° C for periods of up to 1 h. After fixation in buffered osmium<sup>9</sup> the sections were dehydrated and embedded in 'Araldite'. Thin sections were examined electron microscopically, initially without any contrast enhancement. After identification of the sites of barium sulphate localization, the thin sections were stained with lead citrate to enhance the photographic image. Correlated light microscope 15 $\mu$  sections were examined after converting the reaction product to the sulphide as in the Gomori methods for acid phosphatase<sup>10</sup>.

A moderate concentration of enzyme reaction product was observed overlying organelles with the morphological characteristics of lysosomes<sup>11</sup> (Fig. 1). There is good correspondence between the form of organelles stained by methods for acid phosphatase<sup>12</sup> and those observed in this study. The enzyme reaction product which in this case appears to represent sites of aryl sulphatase type B (ref. 13) has a similar lysosome-specific localization, in liver sections after 25–30 min incubation. There was no artefactual staining of nuclei as is often the case with acid phosphatase methods utilizing beta-glycerophosphate as a substrate.

The distribution of aryl sulphatase seems to be heterogeneous in nature. The reaction product does not appear over all the organelles which correspond to the accepted morphological appearance of subcellular bodies belonging to the lysosome family. Serial sections were examined to ensure that the reaction product was not concentrated in areas of the organelles which did not appear in any particular section. It is not possible to state at present whether this heterogeneity of distribution indicates a true differential localization of lysosomal enzymes or is caused by specific inhibition of particular enzymes. The differential distribution of small quantities of enzymes is of course difficult to detect by these insensitive histochemical methods. Hayashi<sup>15</sup> has, however, demonstrated

Fig. 1. Electron micrograph of a lysosome in mouse kidney proximal tubule cell.  $\leftarrow$  indicates enzyme reaction product of aryl sulphatase technique after incubation for 30 min. Lm, lysosomal membrane. ( $\times 63,000$ .)

Fig. 2. Kidney lysosomes after 45 min incubation. Barium sulphate is concentrated over the bodies of the organelles.  $\leftarrow$ , released enzyme reaction product. M, mitochondrion; Lm, lysosomal membrane. ( $\times 52,500$ .)

qualitatively different distributions of beta-glucuronidase, N-acetyl-beta-glucosaminidase and acid phosphatase activity in various tissues of the rat. Interpretation of the results suggests that a functional differentiation among lysosomes in various tissues may exist.

The restricting nature of the single membrane of lysosomal bodies is observed in sections that are incubated for periods of 1 h. The enzyme reaction product was observed in the cytoplasm surrounding the ruptured organelles (Fig. 2). Incubation in the acid medium at 37° C eventually disrupts the membrane, thus releasing the enzymes and producing the artefactual staining. The reaction product often appears to be concentrated near the lysosomal membrane in such over-incubated sections. Control sections incubated in medium free of substrate showed no reaction product even after incubation for 90 min. Further investigations are required regarding the heterogeneity of distribution of the various lysosomal enzymes as well as the nature of substrates on which the enzymes act *in vivo*.

## MICROBIOLOGY

Aggregation in a Thermophilic *Oscillatoria*

*Oscillatoria terebriformis* (Ag.) Gom., isolated from Hunter's Hot Springs, Lakeview, Oregon, shows both gliding and flexional movements of individual trichomes. Laboratory clone populations of trichomes, when dispersed by agitation, rapidly aggregate in still liquid medium. If the population density is high enough aggregation produces a single dense ball or clump. The clump may be redispersed by swirling or shaking. Fig. 1 demonstrates the rapidity of the aggregation phenomenon at an optimal temperature of 47° C. Growth in an unagitated flask takes place with essentially all of the trichomes in a single ball. At Hunter's Hot Springs and other Oregon hot springs this species forms dark brown mats up to about 2 mm in thickness from 53° C to about 47° C, which corresponds closely to the optimal growth temperature range in the laboratory. Growth medium consisted of the following (1 l. of distilled water): 0.1 g of nitrilotriacetic acid; 1.0 ml. of trace element solution (1 l. of water, 0.5 ml. of concentrated sulphuric acid, 2.28 g of manganese sulphate, 0.5 g of zinc sulphate, 0.5 g of boric acid, 0.025 g of copper sulphate, 0.025 g of sodium molybdate, 0.045 g of cobalt chloride); 0.2 mg of ferric chloride; 0.06 g of calcium sulphate; 0.1 g of magnesium sulphate; 0.008 g of sodium chloride, 0.103 g of potassium nitrate, 0.689 g of sodium nitrate; and 0.111 g of sodium phosphate. The pH was adjusted to 8.2 with sodium hydroxide, and was about 7.5 after autoclaving. Field material, when removed by suction and dispersed in a vessel, also aggregates rapidly, as in the laboratory cultures.

Fig. 1. The aggregation of *O. terebriformis* at 47° C and 1,000 lumens/ft.<sup>2</sup> in a glass Petri plate with a radius of 4.5 cm, containing 20 ml. of culture medium. (A) Immediately after dispersal; (B) 10 sec after dispersal; (C) 20 sec; (D) 30 sec; (E) 40 sec; (F) 50 sec; (G) 60 sec; (H) 70 sec; (I) 90 sec; (J) 130 sec; (K) 4 min; and (L) 30 min. In the last frame streamers are beginning to radiate from the central mass.

Fig. 2. Two aggregated masses of *O. terebriformis* in unagitated liquid culture medium with typical streamers of roped trichomes extending from the peripheries. The diameter of each mass is approximately 2 cm.

Fig. 3. A mat of *O. terebriformis* overlying and bordering a mat of a species of *Synechococcus* in Hunter's Hot Springs, Lakeview, Oregon. Tufts and streamers of trichomes may be seen extending from the edge of the dark *Oscillatoria* mat. The length of the field pictured is approximately 6 cm.

The mechanism of aggregation is now being investigated, but is still not well understood. It appears to be a result, first, of strong flexional movements of the trichomes, already reported for this species<sup>1</sup>. When trichomes contact they glide against each other and coil. The rope like strands formed continue to flex and undergo contortions and apparent contractions. In the case of high trichome density, the movements result within a few seconds in a single interwoven network which contracts evenly into a single clump. With a lower density of dispersed trichomes the network formed is irregular. At very low densities numerous small clumps form. Reducing the length of the trichome with a blender also results in numerous small clumps. After the aggregation of trichomes of normal length has been completed, the dense mass gradually "sends out" streamers of roped trichomes around the periphery (Fig. 2). Such streamers are also quite apparent at the edges of the *Oscillatoria* mat in the hot springs (Fig. 3).

The aggregation phenomenon seems to be a result chiefly of undirected flexional and contractional or torsional movements<sup>2</sup>, and there is no evidence of chemotactic attractions. There is more than microscopical evidence to show that the motility of individual trichomes is required for aggregation. *Oscillatoria* can be killed by various methods which do not cause immediate cell lysis, but which do stop individual motility and aggregation. A weak IKI solution or 4 per cent formalin was sufficient. Momentary freezing or drying and subsequent rewetting were also effective. A reversible inhibition of motility and aggregation was caused by solutions of sodium

chloride of more than 0.3 per cent and by pH below about 6.5. The aggregation rates were normal for a time in distilled water, but declined in medium of increased viscosity. Nevertheless, the process still occurred slowly in a methyl cellulose solution of 6.7 g/l. A 0.2 per cent solution of the detergent 'Tween 80' had no apparent effect on aggregation or redispersal.

Preliminary experiments have shown that the addition of chelating agents (for example, 0.5 mmolar EGTA) stops gliding and flexional movements, as well as aggregation. Complete activity was restored by the addition of calcium ions, but not by magnesium or sodium ions. These results suggest that a protein contractility phenomenon may be involved in all types of *Oscillatoria* movements<sup>3</sup>.

The rate of aggregation was temperature dependent below about 37°C and was saturated to about 52°C, above which it declined steeply to the lethal temperature of 54–55°C. Exponential phase cultures grown in the light aggregated in both light and darkness above about 27°C, but cultures which had been starved of light for 24 h or more at 45°C showed no movement in the dark. A subsequent exposure to light resulted in an aggregative response within a few minutes. The dark aggregation of normal light grown cultures was stopped almost immediately by  $2 \times 10^{-4}$  molar 2,4-dinitrophenol (DNP), but the rate in the light was still substantial. It appears that adenosine triphosphate is available as an energy source for motility from both photo- and oxidative-phosphorylations.

Recently, a mutant lacking flexional and gliding motility has been recovered from the normal clone culture. This material shows no ability to aggregate.

The freedom of trichomes to disperse with agitation depends on the presence of one or more species of bacteria during the growth of the culture. In axenic cultures, a large quantity of excreted gel like material accumulates in the centre of the growing clump; this tends to bind at least portions of most of the trichomes. This material is apparently metabolized as rapidly as it is released in bacterized cultures and in nature.

In this species of filamentous blue-green alga the ability to aggregate seems to have a clear adaptive significance. In hot spring drainways most of the blue-green algae hold their position in the flowing water by forming mats in which the trichomes or cells are bound together by gel like substances (unpublished work of T. D. Brock). In the case of thermophilic *Oscillatoria terebriformis* the integrity of the dense mat is maintained principally by the coiled and interwoven disposition of the trichomes. The photosynthetic thermophiles occupy only the few surface millimetres and are underlain by gelatinous layers of filamentous heterotrophic organisms. *O. terebriformis* completely dominates the surface of this undermat in its optimal growth temperature range, and so it is believed that the non-mucilaginous nature of the *Oscillatoria* layer and the movements of the trichomes provide a very poor substrate for the colonization and growth of other thermophilic species which could potentially occupy the same temperature range<sup>4</sup>.

Field observations also indicate an adaptive value for gliding movements in this *Oscillatoria*. When flow patterns of the thermal stream shift, resulting in temperature changes at various points in the drainway, *Oscillatoria* is able to rapidly colonize the gelatinous mat composed of other more sedentary species if the 53°–54°C boundary is extended away from its edge. On the other hand, if the temperature at the edge of the mat is gradually increased, the mat seems to be able to retract towards lower temperature without the mass mortality that would result from extended exposures to temperatures over 54°C. When patches of mat in the optimal temperature range were cut out and removed from the underlying sand-gravel substrate, re-invasions by migrating *Oscillatoria* from the edges occurred at the rate of up to 1 cm/h.

### Significance of the Characteristic Chemical Pattern of Gram Positive and Gram Negative Bacterial Cell Walls

GRAM positive and Gram negative bacteria are known to have different and characteristic patterns of chemical composition of their cell walls. Gram positives usually have a relatively small number of amino-acids and Gram negatives have a much larger number<sup>1</sup>. Some Gram positive genera are characterized by the possession of a specific sugar, whereas Gram negatives are not<sup>2</sup>, and they also have fewer amino-sugars and more lipids than Gram positive walls<sup>1</sup>.

These facts have been widely interpreted as implying that there is a phylogenetic significance in these compositions, but it is common experience that single strains of bacteria may have variants of both staining types. In this laboratory, it has been observed that Gram positive variants of *Haemophilus* have the Gram positive pattern of cell wall composition, whereas the original strains are Gram negative in both composition and staining reaction. Similarly, it has been pointed out that *Neisseria* species have the Gram negative cell wall<sup>3</sup>, whereas they are usually regarded as related to other cocci, most of which are Gram positive, and may themselves be variable.

Thus the conclusion that this taxonomy provides conclusive evidence of bacterial affiliations is badly at variance with other available evidence, and we suggest two explanations to resolve this anomaly. The first is that the Gram negative pattern may be caused in part by blocked synthesis of the Gram positive pattern. The second is that the differences may be accentuated by experimental procedures.

In a recent investigation, one Gram positive strain of *Corynebacterium cervicis* was found to contain 6-deoxytalose, rhamnose, mannose, glucose and galactose in its cell walls, whereas a Gram negative variant had mannose, glucose and galactose only; but the glucose was in significantly greater quantity. This is explicable as a blockage of rhamnose synthesis at glucose<sup>4,5</sup>. It has also been shown<sup>6</sup> that 6-deoxytalose is a hydrolysis product of rhamnose, and presumably the same blockage caused the loss of this also. Thus the original pattern, which is significantly like that of *Actinomyces bovis*, is lost in the variant. Similarly, lysine and DAP rarely occur in comparable quantities together in Gram positives<sup>2</sup>, but frequently do so (in our experience) in Gram negatives. DAP has been shown to be a precursor of lysine<sup>7,8</sup>, so that this difference may also be explained by blockage of synthesis. Further similar illustrations could be adduced from work inside and outside this laboratory, especially where loss of Gram positivity and blockage of synthesis are simultaneously produced by the presence of penicillin. For example, glucosamine-6-phosphate accumulated in a penicillin-induced variant of *Haemophilus influenzae*, replacing glucosamine that was present in the original strain, the former being a precursor of the latter<sup>9</sup>.

The second explanation is that where analyses are conducted by chromatography, adjustment of the technique to detect the larger quantities of a smaller range of

amino-acids in Gram positives may result in the smaller quantities of other, supposedly atypical, amino-acids failing to register. Where we compared the results of thin-layer chromatography with those given on the same extracts by a Technicon auto-analyser, it was found that only four major and six minor amino-acid components could be detected by chromatography in the cell wall of a group *D Streptococcus*, whereas twenty-two minor components were found by the autoanalyser, and these were those supposedly characteristic of Gram negatives, and absent from Gram positives. In this case, very careful control of the purity of the cell wall preparations, before hydrolysis, was made by the electron microscope, to avoid the risk of contamination by residual cytoplasm.

Thus the chief difference between Gram positive and Gram negative cell wall composition may prove to be the balance between the precursors and their synthetic products; the former being present in smaller proportions, even in the Gram positive wall.

It also seems that the theory of degenerative evolution of some Gram negative bacteria, from Gram positive ancestors, advanced by Bisset<sup>10</sup>, is not necessarily contradicted (as has been suggested<sup>3</sup>) by the evidence of cell wall analysis.

### Purification and Concentration of Influenza Virus by Auto-aggregation

THE suggestion that influenza virus tends to aggregate was based on the assumption that the increase in titre of suspensions treated with trypsin is due to disaggregation<sup>1</sup>. Precipitation of partially purified influenza virus by dilution with distilled water has previously been observed<sup>2</sup>.

During the dialysis of allantoic fluid containing influenza A virus we noticed a precipitate. After separation the haemagglutinin was confined to the precipitate while the supernatant was almost free from haemagglutinin. To investigate this phenomenon further a standard test was developed. All the virus suspensions used were first centrifuged at 1,100*g* for 10 min and then dialysed against 50 volumes of tap or distilled water at 37° C. Separate specimens were collected at hourly intervals and again centrifuged at 1,100*g* for 10 min. Supernatants and deposits were then assayed for virus activity, protein content and electrical conductivity. The results of the standard test with fresh allantoic fluid suspensions of influenza B are shown in Table 1.

An increase in virus activity in the deposit with loss of protein and electrolytes in the supernatant is evident. The protein purification factor is significant and compares favourably with results from other methods<sup>3-5</sup>. Similar results were obtained with influenza A allantoic fluids, influenza C amniotic fluids and calf kidney tissue culture fluids of influenza B. In a standard test, Newcastle disease virus (Herts strain), parainfluenza 1 (laboratory strain), bovine parainfluenza 3 (Frant strain), adenovirus 11, echovirus 7 and vaccinia (Jenner) showed no increase of haemagglutinin in the deposit.

Haemagglutinin tests were performed by the Takátsy microtitration method<sup>6</sup> with red blood cells appropriate to the virus tested. Infectivity titres of influenza virus were determined by haemadsorption on calf kidney cells.

The relatively low centrifugal force used to concentrate the influenza virus suggested aggregation, and this was confirmed by electron microscopy. Negatively stained specimens from deposits showed aggregates of closely packed particles with influenza morphology<sup>7</sup> up to several microns in size.

Aggregation under the conditions of the standard test was not prevented by specific antiserum, receptor destroying enzyme, inactivation by 1:10,000 formalin or by heating at 56° C for 30 min. Because of the unspecific character of the phenomenon the term "auto-aggregation" is suggested.

The amount of aggregation is inversely proportional to the molarity of the solutions against which dialysis is performed. This was established with caesium chloride, potassium chloride, potassium dihydrogen phosphate and sodium hydrogen phosphate. For example, in experiments where the molarities of sodium chloride and sucrose used for dialysis were varied by two-fold steps from 0.4 to 0.025, the haemagglutinin titre of the supernatant at the end of dialysis fell from 2,560 to 160 and that of the deposit rose from 320 to 1,280.

The pH of the solutions had no apparent effect over the range pH 5–pH 9, because when the virus suspension was dialysed against M/15 Sørensen phosphate buffers over this range it gave the same haemagglutinin titres in the deposits. The temperature at which dialysis is performed is not critical because the same titres were obtained at 37° C, room temperature and 4° C.

Some aggregation takes place when influenza allantoic fluid is allowed to stand at room temperature for 4 h (Table 1). Addition of salts to a final concentration of 0.2 molar or greater prevents this aggregation. This effect has been used in this laboratory for stabilization of influenza virus suspensions.

The aggregates formed after dialysis are not easily dispersed even by vigorous shaking in saline. A four-fold increase in titre was found after treatment of the re-suspended material with 2 mg/ml. crystalline trypsin at pH 7.6 for 30 min at 37° C or with 1 per cent Difco trypsin.

The aggregation of influenza virus seems to be a property of the virus envelope for the soluble antigen which is a common factor of the whole influenza sub-group of myxoviruses did not aggregate under the conditions of the standard test. On the other hand, after disaggregation the infectivity seems to be preserved and corresponds to the haemagglutinin titre.

\* Protein determinations by the Folin phenol method<sup>4</sup>.

† Units of haemagglutinin/mg of protein (purification factor).

The phenomenon of auto-aggregation is eminently suited to be a simple and economical method of partial purification and concentration of influenza virus for vaccine production or an intermediate step in more demanding purification procedures. Auto-aggregation, because it is limited to the influenza sub-group, can also be used as a criterion in the classification of myxoviruses.

We thank Dr D. J. Bauer for his comments and helpful criticism and Mr E. A. Savage for performing the protein determinations.

## BIOCHEMISTRY

### Albumin Mexico, a New Variant of Serum Albumin

AN inherited variant of albumin (albumin Naskapi) has recently been described which has an electrophoretic mobility greater than that of common albumin (albumin A)<sup>1</sup>. This variant is relatively common in many North American Indian tribes, but it has not been found in the United States white and negro sera so far tested, nor in many European sera. We describe here a further variant which was discovered while examining a group of sera from Mexico. This variant moved slower than common albumin, but faster than the variant albumin B which has been described in several European and American families<sup>2</sup> (Fig. 1).

Starch gel electrophoresis was carried out with whole serum with Ashton and Braden's discontinuous buffer system at pH 8.6 (ref. 3). The gels were prepared from hydrolysed starch (Connaught) at a concentration 25 per cent greater than that recommended by the manufacturer. The electrophoresis was performed in a vertical

Fig. 1. Relative electrophoretic mobilities of albumin variants.

Fig. 2. Albumin variants, starch gel electrophoresis in Ashton and Braden's buffer. 1, A/Mexico; 2, A/B; 3, A/Mexico; 4, A/Naskapi.

system with a constant voltage of 9 V/cm and the run was continued until the "borate-line" had migrated 12–15 cm from the origin.

A total of 281 sera from Mexican mestizo communities were studied. In addition, 20 Mazatec (Huautla de Jimenez), 123 Zapotec (Guelatao de Jurez) and 263 Maya (Yucatan) Indians were studied, as well as other sera (Table 1). The populations are described elsewhere<sup>1,4,6</sup>. With few exceptions, the individuals sampled were not closely related. Sera from the family of an individual from Mexico City with the Mexican albumin variant were also studied.

Table 1. DISTRIBUTION OF ALBUMIN A/A (COMMON ALBUMIN) AND A/Me (COMMON ALBUMIN AND ALBUMIN MEXICO) IN MESTIZO AND MEXICAN INDIAN GROUPS

Population	Location	Total	A/Me
Maya	Yucatan	263	0
Mazatec	Huautla de Jimenez	20	0
Zapotec	Guelatao	123	1
Mestizo/Zapotec	Pochutla	36	1
Mestizo/Mixtec	San Pedro Mixtepec	20	0
Mestizo/Mixtec	Ometepec	20	0
Mestizo/Mixtec	Cuajinicuilapa	20	0
Mestizo	Tlaxcala and Hidalgo States and Mexico, D.F.	185	10

Albumin Mexico was not found in any of the following American Indian and Eskimo sera: Naskapi, Canada, 151; Montagnais, Canada, 112; Sioux, US, 160; Athabaskan, Alaska and Canada, 20; Tlingit, Alaska, 100; Haida, Canada, 365; Quechua, Peru, 100; Cashinahua, Peru, 92; Eskimos, Alaska, 443 (ref. 1).

Blood was collected by venipuncture and the serum separated by centrifugation. The Mexican sera had been stored at  $-25^{\circ}\text{C}$  for about 5 yr–1 yr when the electrophoresis experiments were carried out.

Twelve of the sera (excluding the family sera) contained a variant (in addition to the common albumin) the mobility of which was slower than common albumin. The variant will tentatively be referred to as albumin Mexico. One albumin Mexico variant was found among the Zapotec Indians from Guelatao and another from Pochutla where the Indian component of the population studied is also Zapotec. Ten of the albumin Mexico variants were found in the mestizo communities. None of the other sera tested had a variant with the same mobility as albumin Mexico. The albumin Mexico is shown in Fig. 2 where it is compared with albumin A (common albumin), albumin B and albumin Naskapi.

One parent and three of the sibs of the albumin Mexico propositus had albumin Mexico in addition to albumin A (Fig. 3). This segregation is consistent with simple autosomal co-dominant inheritance. The same mode of inheritance has been reported for the other albumin variants.

Fig. 3. Segregation of albumin Mexico in a Mexican family. A/Me heterozygotes are indicated by the half darkened circles (females) or squares (males) and A/A homozygotes by the empty box. The Gc phenotypes (1-1 or 2-1) of the family members are also shown. The propositus is the first offspring.

The number of apparent heterozygotes among the offspring is rather more than expected, but this could be the result of chance.

There is a diagram in Fig. 1 which shows the relative mobilities of the albumin variants which have been compared in this laboratory. Albumin A is the common form of albumin. Albumin B is the slow moving variant referred to as "very slow" by Weitkamp *et al.* (unpublished work). This apparently is the slow moving variant found rarely in Europeans and described originally as "bis-albumin". Albumin Naskapi<sup>1</sup> has a mobility faster than albumin A. We have compared an albumin variant found in the serum of a Navajo Indian by Dr J. L. Robbins of Salt Lake City and found it to be the same as albumin Naskapi. From this, it appears that the samples designated as "faster" by Weitkamp *et al.*<sup>2</sup> have the same mobility as albumin Naskapi. The albumin described by Wieme has the fastest moving mobility of any of the albumins tested. Quantitative comparisons of these and other variants will be given elsewhere (Melartin, in preparation).

Additional family studies will be necessary to confirm the apparent inheritance of this trait. If this variant is inherited, however, as most of the others seem to be<sup>4</sup>, then these Mexican populations would be particularly interesting to study. It may be possible to identify family segregating for three (or more) variants to determine if they segregate at one or more loci. Furthermore, using data from families segregating for albumin B<sup>2</sup>, and albumin Naskapi<sup>1</sup>, data have been obtained which suggest close linkage between the albumin and Gc loci. These populations could be used for more detailed studies of this linkage.

We are indebted to Drs Robinson and Weitkamp for albumin variant sera. The Mayan specimens were provided by Drs E. Giles and M. Yokoyama.

This work was supported in part by US Public Health Service grants.

## Effect of Inhibitors of Protein Synthesis on the Plastic Deformation and Growth of Plant Tissues

MANY workers have confirmed that auxin increases the irreversible deformability ("plasticity") of plant tissues, for example, coleoptiles or storage tissue<sup>1-3</sup>. A primary effect of auxin in growth may therefore be to promote extensibility of the cell wall, a change which precedes cell expansion. The mechanism of action of auxin in causing this change is not known, although it has been suggested that the substance affects the linkage of pectin chains to each other.

In the past few years it has become clear that nucleic acid and protein synthesis are required for auxin-induced growth. This is suggested partly by the finding that various inhibitors of the synthesis of these macromolecules prevent the growth-promoting action of auxin. As yet it is not clear which part of the growth process in plant cells is controlled by auxin-induced proteins, although Noodén and Thimann<sup>4</sup> have suggested that proteins affecting the condition of the wall might be particularly important.

In this note we describe experiments performed to test the possibility that auxin-induced plasticity is dependent on protein synthesis. This has been studied by examining the effects of inhibitors of protein synthesis on the irreversible deformability of plant tissues. A similar approach has been taken by Cleland<sup>5</sup> and Morré<sup>6</sup> using the inhibitor of RNA synthesis, actinomycin D, but these workers rather differed from each other in their conclusions.

In the present experiments, we have used three methods for measuring the irreversible deformation under static external load. The first method (Fig. 1C), employing wheat coleoptile sections, is identical to that described by Tagawa and Bonner<sup>2</sup>. In the second method (Fig. 1B), coleoptile sections were stretched by a 10 g weight. The

Fig. 1. Methods used to measure irreversible tissue deformation.

increase in length and the recovery when the weight was removed were measured with a travelling microscope. In the third method, cylinders of potato tuber tissue were arranged as shown in Fig. 1 and the bending and recovery were again measured with a travelling microscope. In each experiment the cylinders were cut from a single large tuber, ensuring highly uniform material. All experiments were carried out in glass containers saturated with water vapour, at room temperature (approximately 22° C) in the light. The techniques were carefully checked to establish that changes in material other than the plant tissues, for example that used for attaching the weights, did not contribute to the measured deformations.

The coleoptile sections and potato cylinders were placed in water for 1 h or in solutions of the inhibitors of protein synthesis, actidione (cycloheximide) or D-chloramphenicol. They were then transferred to solutions of indoleacetic acid (IAA) for 90 min, a time sufficient to cause the maximum increase in plastic deformation. Except for the auxin control the IAA solutions also contained one of the inhibitors. Other control tissues were kept in water throughout. After these treatments, measurements of deformation were made for 30–50 min. Fig. 2 shows that the tissues behaved in the expected manner towards IAA, with respect to their plasticity. Fig. 2 also shows the result of treatment with IAA in the presence of actidione (10 µg/ml.). This substance strongly reduced the plastic component of the IAA-induced deformation,

The arrows show the time at which the load was removed. ○, Treatment with water; ×, treatment with IAA (10 µg/ml.); ●, treatment with IAA + actidione (10 µg/ml.).

Table 1. EFFECTS OF ACTIDIONE AND CHLORAMPHENICOL ON RESIDUAL AND AUXIN-INDUCED PLASTICITY AND ON WHEAT COLEOPTILE GROWTH

Treatment	Plasticity Index			Per cent increase in coleoptile length
	Potato	Coleoptile (B)	Coleoptile (C)	
Water	100	100	100	31
IAA (10 µg/ml.)	150	120	124	59
IAA + actidione (1 µg/ml.)	100	—	106	—
IAA + actidione (10 µg/ml.)	93	60	110	6
IAA + chloramphenicol (2 mg/ml.)	100	63	117	44
Actidione (1 µg/ml.)	100	—	100	—
Actidione (10 µg/ml.)	90	3	89	4
Chloramphenicol (2 mg/ml.)	93	31	106	30

in two cases (A and B) to a level even lower than the water control. Similar effects were obtained with other concentrations of actidione and with chloramphenicol (Table 1). In this table the percentage plasticity in the water controls was taken as 100 and all the others were related to this (the plasticity index). Other coleoptile sections were treated with inhibitors and auxin in the same manner but afterwards were transferred to water for 24 h when their lengths were determined (Table 1). The effects of the inhibitors on auxin-inducible deformation were clearly paralleled by effects on the growth of the sections.

These results indicate that protein synthesis seems to be an essential event in the mechanism of auxin-induced plasticity. Auxin possibly controls the synthesis of enzymes which "soften" the cell wall before expansion of the cell by turgor forces. It is interesting to note that the residual plasticity present in the water controls was severely reduced by treatment with the inhibitors. This could mean that the protein responsible for promoting plastic changes has a rapid turnover time, that is, a short life. Cleland<sup>5</sup> found that auxin increased plasticity even though 90 per cent of the RNA synthesis was arrested by actinomycin D. This finding considered with the others presented here might suggest that the "message" for the proteins controlling plasticity has a rather long life and that in these systems auxin might not act on RNA synthesis but at a subsequent stage in protein synthesis. Masuda *et al.*<sup>7</sup> have reached a similar conclusion on the basis of their studies on RNA metabolism in growing coleoptiles.

Note added in proof. Results have recently been published<sup>8</sup> which show that actidione markedly reduces auxin-inducible plasticity in soybean hypocotyls.

### Protein and RNA Synthesis in Trisomic Down's Syndrome Leucocytes

IN Down's syndrome (mongolism) increased activities have been reported in the leucocyte enzymes alkaline<sup>1,2</sup> and acid<sup>3</sup> phosphatase, glucose-6-phosphate dehydrogenase (G-6-PD) (ref. 3), galactose-1-phosphate uridyl transferase<sup>4</sup> and 5-nucleotidase<sup>5</sup>. It has been suggested that such increases may be due to the siting of structural genes for the relevant enzyme on the trisomic "G"

Fig. 1. Rates of incorporation of <sup>14</sup>C-glycine and tritiated uridine. ●, Down's syndrome; ○, control.

group autosome<sup>1</sup>. This seems unlikely, however, at any rate in the case of G-6-PD, for there is good evidence that the structural gene for this enzyme is carried on the X chromosome<sup>3,4</sup>. An alternative possibility is that the trisomic autosome may carry genetic material responsible for regulation of protein synthesis.

Increase in enzyme activity may be due to either enzyme activation or enhancement of *de novo* synthesis of enzyme protein. This article presents evidence that, in primary trisomic Down's syndrome, the rates of leucocyte RNA and protein synthesis are increased.

Leucocytes were obtained from children with primary trisomic Down's syndrome and mentally subnormal controls matched for age, sex and domicile. All subjects appeared to be free from infection at the time of the investigation. 10 ml. of heparinized blood were collected, and leucocytes isolated under sterile conditions by sedimentation in dextran<sup>5</sup>. Total and differential cell counts were performed after thorough mixing with a mechanical mixer. In accordance with the experience of others<sup>3</sup>, this method of leucocyte isolation yielded differential counts which were similar in subjects with Down's syndrome and controls.

Approximately  $10 \times 10^6$  leucocytes were collected by gentle centrifugation (80g for 15 min at 4° C) and resuspended in either 2 ml. of autologous plasma with 6-<sup>14</sup>C-urotic acid (0.4 µc/ml.) or in 2 ml. of culture medium (Difco T.C. 199 containing 30 per cent pooled human serum without antibiotics) containing U-<sup>14</sup>C-glycine (3 µc/ml.) and 5-tritiated-uridine (3 µc/ml.). After incubation at 37° C for 4 h the leucocytes were washed once with 0.85 per cent saline. Protein and RNA were extracted, using a modification of the Schmidt-Tann-

Table 2. INCORPORATION OF <sup>14</sup>C-GLYCINE INTO LEUCOCYTE PROTEIN

	Incorporation of <sup>14</sup> C-glycine into protein (c.p.m./10 <sup>6</sup> leucocytes)	
	Control	Down's syndrome
Mean	122.9	171.0
S.D.	42.6	63.8

P*	< 0.01	

\* Calculated from *t* test for paired observations.

hauser technique<sup>6</sup>, but alkaline hydrolysis was omitted when tritiated uridine was the RNA precursor<sup>6</sup>.

The results are summarized in Tables 1 and 2. Incorporation rates of <sup>14</sup>C-urotic acid or tritiated uridine into leucocyte RNA were higher in Down's syndrome than in controls ( $P < 0.01$  and  $< 0.02$  respectively) (Table 1). The rate of incorporation of <sup>14</sup>C-glycine into leucocyte protein was also higher in Down's syndrome leucocytes than in controls ( $P < 0.01$ ) (Table 2). No relationship was observed between either age or sex. In individual subjects, a positive relation was apparent between the rates of incorporation of <sup>14</sup>C-glycine and tritiated uridine (Fig. 1).

These results indicate that rates of protein and RNA synthesis are increased in primary trisomic Down's syndrome leucocytes during short term culture.

### Relative Susceptibilities of Isotopically Labeled and Unlabeled Nuclei to Deoxyribonuclease I

THE use of tritiated thymidine as a specific precursor of DNA is well established in the study of DNA synthesis and the kinetics of cell population. The usefulness of the method depends on the conservation of labelled DNA and on the rapid catabolism of non-utilized nucleoside. During experiments in which mammalian nuclei were treated with deoxyribonuclease (DNase I) I found that labelled nucleic acid was more labile to the enzyme than DNA which carried no isotope—an observation which may have a bearing on the use of radioactive precursors.

Murine lymphoma cells of strain L 5178Y in culture were labelled during exponential growth by the addition of 0.25 µc. of <sup>14</sup>C-formate/ml. of Fischer culture medium<sup>1</sup>. Initial cell numbers were such that after 70 h of growth in the isotope between  $2$  and  $5 \times 10^5$  cells/ml. were collected. The cells were washed with unlabelled medium, and the nuclei isolated by seventy to eighty manual reciprocations in a 'Teflon' glass homogenizer, size A. The nuclei were treated with DNase I at a concentration of 160 µg/ml. suspension at room temperature. The suspension consisted of  $10^7$  nuclei/ml. of Creasey Stocken medium C, pH 7.2, augmented with 0.02 molar magnesium ions<sup>2</sup>. Samples of the suspension were withdrawn in duplicate at various times, and the enzyme action was stopped by the addition of ice-cold 0.2 molar perchloric

\* Calculated from *t* test for paired observations.

Fig. 1. Percentage of specific activity remaining in labelled nuclei after digestion with 160 µg/ml. DNase I, as a function of time.

acid. DNA was estimated by spectrophotometry after extraction by a modified Schmidt-Tannhauser procedure<sup>3</sup>. Radioactivity was estimated in a 'Tracerlab' LSC 30 liquid scintillation counter. Similar experiments were also performed on nuclei which had been labelled with tritiated thymidine by the addition of the isotope in eight fractions of 0.01 µc./ml. spread over the 70 h period of growth. A fractionated treatment was used because there is evidence that cell suspensions degrade thymidine<sup>4</sup>. The specific activities of the DNA were expressed as a function of the control (untreated nuclei), and plotted against time of enzyme action (Fig. 1).

It is apparent that the enzyme preferentially removes labelled DNA, particularly in the case of DNA labelled with tritium. A high concentration of enzyme was used here to emphasize the effect, but a noticeable decrease in specific activity was also obtained after the first few minutes with concentrations of 30 µg/ml. Some preliminary results along similar lines have been obtained using kidney nuclei from rats treated with folate<sup>3</sup> which were flash-labelled with tritiated thymidine 1 h before they were killed. The fall in specific activity after treatment with DNase was much less than with the cultured cells exposed to label for 70 h, but still appreciable, and this effect is being further investigated.

The explanation of this effect is unknown at present, but two possibilities may be considered. The nuclear DNA may be so damaged by the radiation from the isotope label that the active regions are more intrinsically labile to enzyme attack. Alternatively, the damaged DNA is undergoing repair and the action of the DNase I is to hydrolyse already excised material. The greater effect of the tritium label as compared with the carbon-14 label is probably due to the greater energy absorption from the tritium  $\beta$  particle, although in murine lymphoma cell cultures the number of bases labelled is about ten times higher in the case of carbon-14. It has recently been reported elsewhere that loss of tritium activity from acid-precipitable material after labelling with tritiated thymidine can occur over the course of some hours<sup>5</sup>. This was attributed to the localized absorption of energy from tritium disintegration, because it did not occur after labelling with carbon-14.

The use of carbon-14 or tritium precursors can thus produce cells in which the chromosomal material is changed such that a proportion of the DNA is more labile to enzyme attack. Whereas this effect may have implications in the use of labelling techniques, it is not yet certain what the biological consequences of such lability might be.

I thank Professor L. F. Lamerton and Dr D. M. Taylor for criticism and discussion.

### Formation of Blue Oxidation Product from Psilocybin

Gilmour and O'Brien<sup>1</sup> have reported that a blue colour develops when psilocybin (4-phosphoryl-*N,N*-dimethyl-tryptamine) is incubated with a preparation of rat brain mitochondria. The colour is apparently not dependent on oxygen for its formation, is associated only with the particulate matter and cannot be brought into solution by treatment with various organic solvents, detergents, acid or alkali. The reaction is inhibited (80 per cent) by EDTA.

Experiments carried out in this laboratory and elsewhere provide a reasonable explanation for this phenomenon. Psilocin, the dephosphorylated derivative of psilocybin, forms a deep blue colour on incubation with ceruloplasmin—the copper oxidase of mammalian serum—or with a copper oxidase obtained from the gill plates of *Mytilus edulis*. The reaction is accompanied by the uptake of oxygen<sup>2,3</sup>. The colour has a spectral maximum at about 620–625 m $\mu$  and a smaller peak at 400 m $\mu$ . Although 5, 6 and 7-hydroxyindole derivatives are also oxidized in the presence of both enzymes, only psilocin yields the blue colour. The blue material is a fairly stable free radical (Blumberg, W. E., and Peisach, J., personal communication), while the free radicals formed from other ceruloplasmin substrates are rather short lived<sup>4</sup>. The reaction catalysed by ceruloplasmin is unaffected by EDTA. This is in contrast to the reactions with other substrates such as *p*-phenylenediamine, which are inhibited by about 50 per cent by EDTA (refs. 5 and 6).

During the formation of blue material in the presence of the *Mytilus* enzyme the colour becomes associated principally with particulate matter and resists extraction with various non-polar solvents. Much of the colour can, however, be brought into solution with molar hydrochloric acid. If psilocin is oxidized in a system with very little protein the blue oxidation product appears to remain soluble.

The oxidative formation of blue colour can also be elicited without enzyme in the presence of ferric ion, which acts as an electron acceptor. As would be expected, EDTA and other chelating agents block this non-enzymatic reaction. When treated with alkali, the oxidation product of psilocin turns pale green, and can readily be extracted into butanol, where the deep blue colour reappears. The blue product can be re-extracted into 0.1 molar hydrochloric acid. The hydrochloric acid solution at this point contains no detectable iron, and the blue colour cannot therefore be due to a metal complex.

With psilocybin neither formation of blue colour nor uptake of oxygen occurs during incubation with ceruloplasmin or with ferric ions. Thus a free, non-esterified phenolic hydroxyl group is required for reactivity. These reactions could be related to those described by Gilmour and O'Brien in two possible ways. First, their psilocybin may have been contaminated with a small amount of psilocin. No evidence for purity was presented. The colour is so intense that even a slight contamination would produce visible colour in their system. Second, because prolonged incubation was required for the colour to

form (16–20 h at 5° C) it seems likely that during this period of time a phosphatase could remove the phosphate and thus expose the free phenolic hydroxyl to oxidative attack either by a copper enzyme or by a metal ion such as the ferric ion. Horita and Weber<sup>7,8</sup> described the dephosphorylation of psilocybin by homogenates of various mammalian tissues, as well as by purified alkaline phosphatase. They found that the psilocin produced in this reaction is transformed into a deep blue colour. The latter reaction may be catalysed by cytochrome oxidase which readily oxidizes psilocin to the blue product at physiological pH (7.4), although the optimum pH for this reaction is 9 (ref. 9). Because Gilmour and O'Brien found EDTA inhibited the formation of blue colour, the reaction probably involves some iron which is either free or loosely bound so as to be accessible to chelating agents. This would also explain why the reaction could take place without oxygen.

I therefore propose that the formation of blue colour from psilocybin in the presence of the brain fractions described by Gilmour and O'Brien be attributed to the following reaction.

This work was supported in part by a grant from the US Public Health Service. I have a research career development award from the US Public Health Service. The psilocin and psilocybin were kindly supplied by Sandoz, Inc.

### Primary Structure Heterogeneity in Ribosomal Proteins from *Escherichia coli*

FUNCTIONAL heterogeneity of ribosomal proteins from *Escherichia coli* is extensive and *in vitro* polypeptide synthesis requires at least six different protein fractions<sup>1</sup>. The structural heterogeneity of ribosomal proteins is even more impressive; on gel electrophoresis of 70S ribosomal protein from *E. coli* about thirty protein bands separate and opinion favours the presence of at least as many distinct proteins<sup>2–10</sup>. Little is known, however, about the extent to which the primary structure of these proteins is related. In this communication a comparison between the amino-acid composition and tryptic fingerprints of eight simplified protein fractions, isolated from 70S ribosomal proteins of *E. coli*, will be made. In addition the purification and some properties of three single ribosomal proteins, one acidic and two basics, will be presented. Fig. 1 gives the results of applying 1 g 70S ribosomal protein (prepared using glacial acetic acid<sup>2,10</sup>) to a column of CM cellulose. Four different peaks were reproducibly resolved. The electrophoresis patterns on polyacrylamide gels (15 per cent) of selected fractions are shown in Fig. 2. As Table 1 shows, the amino-acid compositions of these fractions, determined on a Technicon autoanalyser, are quite distinct. Each fraction contains

at least one amino-acid, the percentage of which is substantially greater or less than the percentage of that amino-acid in any other fraction. The relative difference in the contents of basic over acidic amino-acid residues increases regularly from a value of –7 mole per cent to 12 mole per cent. Tryptic fingerprints confirm the presence of extensive differences in primary structure between each of these fractions; with the exception of fractions 1a and 1b, each fraction shows a different tryptic fingerprint with strong spots uniquely missing or present on comparison with any of the other fingerprints (Fig. 3).

The chief component in peak 1 (compare Fig. 1), called ribosomal A-protein, was purified on DEAE cellulose and hydroxyl apatite until this protein moved as a single band in polyacrylamide gel electrophoresis. From the

Fig. 1. Chromatography of *E. coli* ribosomal protein on CM cellulose. The column (43 cm x 3.2 cm) at 14° C was loaded in two portions: 400 mg of ribosomal protein, dissolved in 20 ml. of starting buffer, 0.005 molar ammonium phosphate, 8.0 molar urea, pH 8.0, was applied to the column and the acidic protein portion was eluted with the same buffer. At tube 60, the second portion, 550 mg of ribosomal protein was applied in a similar manner. The gradient, 600 ml. each of 0.005 molar, 0.10 molar and 0.30 molar ammonium phosphate buffer, all 8.0 molar urea, pH 8.0, was started at tube 140. Protein concentrations were determined by the Lowry method<sup>11</sup>. Circles refer to the tubes (8 ml.) selected for further characterization. Recovery from the column was 88 per cent of the input. Pooled fractions, after dialysis and freeze drying, were recovered in 94 per cent yield. Peak I, 8.7 per cent, Peak II, 14.8 per cent, Peak III, 23.7 per cent, Peak IV, 26.2 per cent, Peak V, 4.1 per cent, Peak VI, 1.0 per cent.

Fig. 2. Electrophoresis on polyacrylamide gels of the CM cellulose fractions indicated by the circles in Fig. 1. The cathode is at the bottom and the origin is indicated by a faint line near the top. Solvent was 8.0 molar urea, 0.3 molar formic acid and 0.06 molar potassium formate, pH 3.5 (ref. 9). Gels of unfractionated ribosomal proteins appear on either end as a control. There is similarity between the band patterns of fractions 1a and 1b.

analysis of the amino-acids of this acidic protein and the number of tryptic peptides on a fingerprint the minimum chemical molecular weight was estimated to be 15,000. The physical molecular weight for ribosomal A-protein was 21,000 (ref. 10), a value greater than found chemically. No terminal amino group could be detected by the dansyl method<sup>13</sup>. Analysis of the amino-acids of the spots eluted from the tryptic fingerprints yielded fifteen authentic peptides. The presence of this acidic protein, ribosomal A-protein, to the extent of a few molecules for each 70S ribosome<sup>6,9</sup> is interesting, and so is the fact that neither washing with 0.5-2 molar ammonium chloride in the presence or absence of EDTA nor centrifugation in concentrated caesium chloride solution releases this protein preferentially from the ribosomes into the supernatant.

Two basic proteins were purified by CM cellulose and hydroxyl apatite chromatography to the level of a single

Lysine	9.2	10.1	11.3	12.4	12.9	12.6	16.0
Histidine	1.9	1.5	2.0	2.6	1.7	2.1	2.4
Arginine	3.9	9.8	5.4	7.7	7.8	9.7	9.3
Excess basic	—	2.4	0.9	3.5	3.6	12.7	11.7
Excess acidic	7.3	—	—	—	—	—	—

Results are expressed in moles/100 moles of amino-acid recovered. The fractions selected are indicated in the chromatogram of Fig. 1. Amino-acid analyses were performed on 22 h hydrolysates. Values for the contents of cysteine and tryptophane are not included in total.

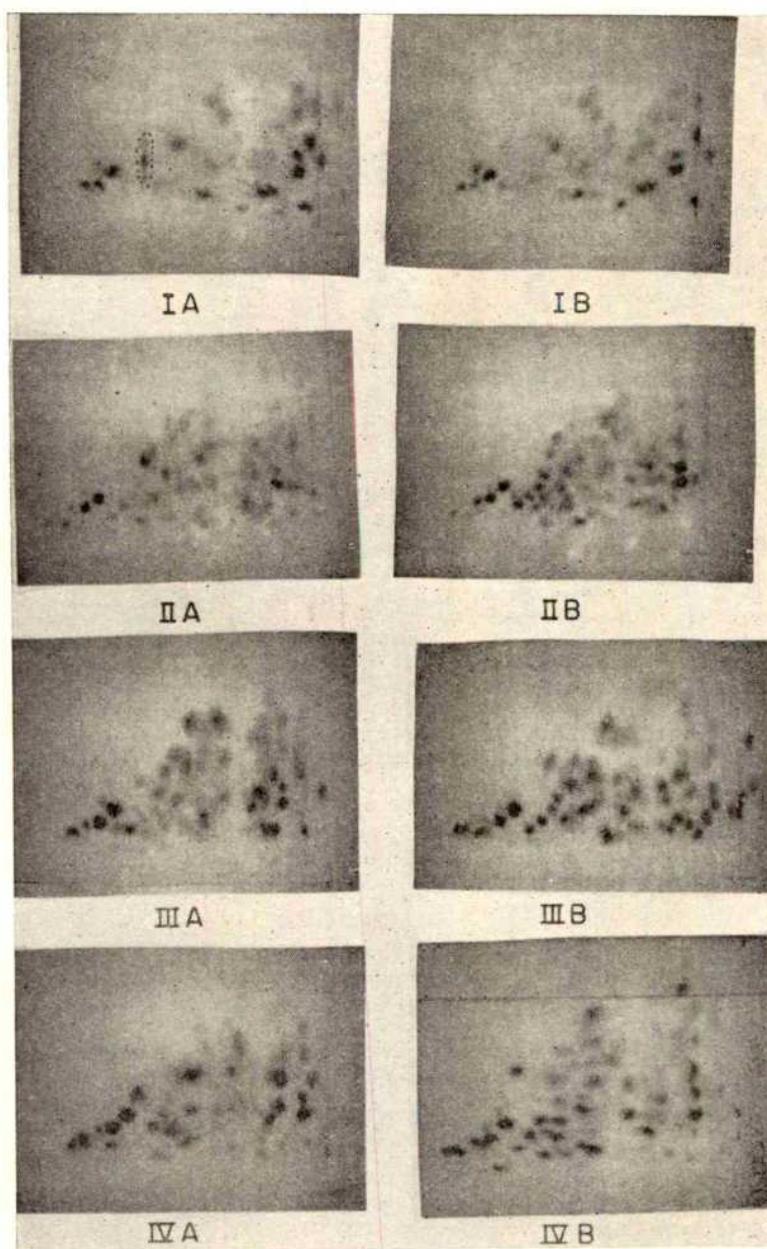

Fig. 3. Tryptic fingerprints of the protein fractions Ia to IVb, indicated by circles in Fig. 1. Each print represents 2 mg of digested chains. The three spots enclosed by a dotted line in the fingerprint of Ia were not reproducible and coincided with the top rod of the rack. The fingerprint technique used has been described before<sup>14</sup>.

Fig. 4. Fingerprint of tryptic digest of two basic ribosomal proteins, 28B (top) and 28D (middle). Superposition (bottom), full circles, 28B; dotted circles, 28D.

band on polyacrylamide gel electrophoresis. Each protein yielded about thirty tryptic peptides, of which a maximum of ten spots overlapped (Fig. 4). On comparison, the tryptic digest of the acidic protein has at the most six spots in common with those of the two basic proteins. The amino-acid compositions of the two basic proteins were distinctly different. Furthermore, the predominant amino terminal was found to be aspartic acid for 28B and alanine for 28D.

From the results of the combined experiments we conclude that (a) 70S ribosomal proteins from *E. coli* contain at least seven proteins of different primary structure, and (b) three single bands, separated by gel electrophoresis of 70S ribosomal protein, originate from proteins of different primary structure.

Because the total number of bands is about thirty, there are probably at least as many distinct proteins. In that case each protein, on the average, is present in the ribosomes in an amount not exceeding a few per cent of the total ribosomal protein at the most, a prediction so far fulfilled for three purified proteins (ribosomal A-protein 3.5 per cent, 28B protein 2.5 per cent; 28D protein 1.4 per cent).

The distribution of these proteins among individual ribosomes is completely unknown. Peptidyl transferase<sup>14,15</sup> is probably contained by all 70S ribosomes. On the other hand, a number of ribosomal proteins of related enzyme activities—for example, co-enzymes, specific for positioning amino acyl sRNA onto the messenger template—but different structures, may not be distributed uniformly throughout all particles<sup>16</sup>. Thus the large degree of structural heterogeneity of ribosomal proteins could be consistent with what seems to be a self-contained biological unit. It is hard to visualize otherwise how so many distinct proteins in a size range of 10,000–40,000 molecular weight<sup>9</sup> could be assembled in a 70S ribosome which accommodates maximally in the order of thirty protein molecules of an average molecular weight of 25,000 (ref. 16).

After completion of this work we received information from R. R. Traut<sup>17</sup>, P. B. Moore, H. Delius, H. Noller and A. Tissières, who have come to similar conclusions with regard to differences in primary structure of ribosomal proteins from *E. coli*. We thank Dr M. Naughton for his help. This work was supported by grants from the US National Institutes of Health.

## Glucose Tolerance after Kwashiorkor

ALTHOUGH permanent organic defects can probably result from prolonged chronic malnutrition, no lesion has so far been proved to follow treated kwashiorkor in man<sup>1</sup>. Persistence of low lactase activity in the jejunal mucosa is a possible exception<sup>2</sup>.

Fourteen children have been studied who had been patients at the MRC Infantile Malnutrition Unit, Kampala, and who had suffered from kwashiorkor between 6.2 and 12.3 (mean 9.5) yr before. Their ages when they were treated for kwashiorkor ranged from 1.0 to 4.4 (mean 1.9) yr. Twelve had had severe and two moderately severe

kwashiorkor<sup>3</sup>. Twenty children whose parents denied a history suggesting kwashiorkor and who came from highly similar environments were studied in parallel. All the children were clinically well nourished; there was no evidence in the children who had had kwashiorkor of their illness, and no evidence of any previous vitamin deficiency. The group who had had kwashiorkor consisted of eight males and six females; ten from the Ganda, three from the Hutu and one from another Bantu tribe. The control group consisted of thirteen males and seven females; nine Ganda, nine Hutu and two from other Bantu tribes. Three (21 per cent) of the post-kwashiorkor children and five (25 per cent) of the control group had enlarged parotids, while two (14 per cent) and four (20 per cent) had slight hepatomegaly, and five (36 per cent) and seven (35 per cent) had splenomegaly. Their mean weights were 29.8 (23.3–38.5) and 25.2 (18.6–39.2) kg and their mean heights 133.8 (119.4–148.6) and 127.9 (113.0–149.9) cm. The mean haemoglobin was 13.1 (7.1–17.6) and 12.9 (8.0–14.6), total plasma-protein 7.7 (6.6–9.4) and 7.3 (6.6–8.4) g/100 ml. (normal range > 7.0 g/100 ml.), and amino-acid ratio<sup>4</sup> 2.1 (1.2–3.2) and 2.7 (1.5–3.7) (normal range < 3.0) in the two groups respectively. There was no statistical difference between any of these figures for the two groups. For the post-kwashiorkor group, body weights were 68.8–98.4 (mean 81.5) per cent, and heights 87.1–100.4 (mean 93.7) per cent of those for a group of well nourished, upper class Ganda schoolgirls of similar ages<sup>5</sup>. Needle biopsies of the liver were performed on nine of the children who had had kwashiorkor. None of them showed any disturbance of architecture but one had slight stellate-fibrosis radiating from the portal areas<sup>6</sup>.

All the children were admitted to the Mulago Hospital, Kampala for the present study, and all received a ward diet containing about 500–600 g carbohydrate (expressed as monosaccharide) daily for 3 days before the tests. All tests were performed between 8.00 and 11.00 a.m. After a 10 h fast a 40 per cent solution (w/v) of glucose was injected intravenously (0.5 g glucose/kg body weight) over 2 min. Capillary blood-glucose was estimated before the injection and at 10, 20, 30, 40, 50 and 60 min after the mid-point of the injection, by a glucose-oxidase method<sup>7</sup>. The concentrations of glucose in the blood (mg/100 ml.) were plotted on semi-logarithmic paper.

The rate of fall of glucose (per cent/min), ( $K_G$ ), was calculated from a straight line drawn visually through the initial linear part of the curve, usually consisting of three or four points, beginning with the 10 min point. Fig. 1 summarizes the mean blood-glucose values at the various

times after injection of glucose. The mean  $K_G$  (calculated from the individual curves) was very significantly lower in those who had had kwashiorkor than in the others ( $t=4.71$ ;  $d.f.=32$ ;  $p<0.001$ ). The mean concentrations of glucose in the blood at 30, 40 and 50 min were also significantly different ( $p<0.02$ ,  $<0.01$  and  $<0.02$  respectively).

In addition to their hospital diet two of the children who had had kwashiorkor were given 150 g glucose daily for 3 days before the test; both had very low  $K_G$  values. Intravenous glucose tolerance shows a decrease at puberty<sup>8</sup>; only two of the children, however, had any evidence of incipient puberty. There was no significant correlation between  $K_G$  and body weight or height in either of the groups.

The cause of the relative impairment in glucose tolerance in the children who had been treated for kwashiorkor requires further study. In old age, decreased intravenous glucose tolerance has been associated with a decrease in the serum insulin response to intravenous glucose<sup>9</sup>. The pancreas is severely damaged in kwashiorkor<sup>10,11</sup>, and malnutrition has been incriminated in the pathogenesis of the chronic pancreatitis which is common in Uganda and other tropical countries<sup>12,13</sup>. Permanent disease of the exocrine pancreas after recovery from treated kwashiorkor, however, has previously been thought to be unlikely<sup>14,15</sup>.

I thank Mr Y. M. Semindi for tracing the children. The haemoglobins were estimated by Dr R. A. Tozer, and the plasma proteins and amino-acid ratios by Mr G. R. Howells. I also thank Professor R. A. McCance for discussion.

## Potential Toxicity of Solutions of Dimethyl Sulphoxide

THE recent popularity of neat or aqueous dimethyl sulphoxide (DMSO) as a solvent for biological work—for example, in tissue culture studies of substances causing enucleation of fibroblasts<sup>1</sup> and of the rate of virus penetration of HeLa cells<sup>2</sup>—has encouraged us to make the following report.

Solutions in DMSO-water (30 : 70 v/v) of aromatic hydrazo- and azo-compounds or carcinogenic amines of the benzidine class readily penetrate certain types of rubber and surgical gloves.

Similar solutions of nitrobenzene and amyl nitrite are rapidly absorbed through the skin to give the characteristic unpleasant symptoms, but negligible penetration or side effects occur when solutions in ethanol, methyl cellosolve or dioxan are used.

Aqueous or neat DMSO is known to be readily absorbed dermally and rapidly distributed throughout the body<sup>3</sup>

and also when used in relatively high concentrations in the solvent, to facilitate the penetration of certain pharmaceuticals and other compounds<sup>4,5</sup>, but our observations (which were noted incidentally to other studies) emphasize the additional caution necessary when toxic, carcinogenic, or perhaps even compounds which are usually regarded as innocuous are handled in solution in this medium. Similar precautions may be necessary for other dipolar aprotic solvents because dimethyl formamide has been shown to be even more active than DMSO in promoting skin penetration by *d*-tubocurarine chloride<sup>6</sup>.

### D-Xylose: Active Intestinal Transport in a Sodium Ion Substituted Lithium Medium

It is becoming increasingly evident that the active transport of a wide variety of substances by the small intestine requires sodium ions<sup>1-4</sup>. The mechanism of active sugar transport, postulated by Crane<sup>5,6</sup>, accounts for the movement of a sugar against its own concentration gradient by virtue of an opposing sodium ion gradient. D-xylose is the only pentose which has been demonstrated to be actively transported by the small intestine<sup>7</sup> and it has been suggested that its mechanism of transport is similar to that of the hexoses<sup>8</sup>. A criterion used to arrive at this conclusion was the apparent dependency of active d-xylose transport on sodium ions.

In 1962, Faust<sup>9</sup> reported that the rates of absorption (disappearance from the mucosal medium) of various pentoses, including D-xylose, by the rat jejunum *in vitro* were not inhibited when lithium was substituted for sodium in the incubation medium. Consequently, it became of interest to investigate whether D-xylose is transported against its own concentration gradient into intestinal mucosa from medium in which sodium is replaced by lithium. It also was of interest to determine the effects of potassium on D-xylose transport.

Fed male rats of the Sprague-Dawley strain, weighing between 200 and 260 g, were used. Cannulated everted sacs of jejunum were filled and incubated at 37° C for 1 h in 100 ml. of gassed (oxygen : carbon dioxide, 95 : 5) sodium, lithium or potassium bicarbonate saline solution, at pH 7.4, containing 6.66 mmoles of either D-xylose, D-ribose, L-arabinose or D-arabinose. When sodium was replaced, equal molarities of either lithium or potassium were used. Lithium or potassium chloride was substituted for sodium chloride, and lithium carbonate or potassium bicarbonate was substituted for sodium bicarbonate. In some cases, an inhibitor was added to both the mucosal and serosal fluids. After incubation the everted sacs were gently wiped with absorbent tissue, then cut open and the tissue placed mucosal side up on strips of Whatman No. 1 filter paper. The tissue was blotted with filter paper and the mucosa was scraped off with a glass microscope slide. The wet mucosa was weighed, lyophilized, and reweighed to determine its tissue water. The dry mucosal tissue was then pulverized in a glass mortar with a glass pestle and mixed with Ba(OH)<sub>2</sub> and Zn(SO<sub>4</sub>)·7H<sub>2</sub>O. After centrifugation, pentoses were determined in the supernatant by the method of Roe and Rice<sup>10</sup> and tissue

pentose concentrations were calculated. No interference with this assay method was observed with control tissue which had been incubated in the absence of pentose.

Table 1 shows that, by using this method, the final concentration of D-xylose within the mucosa in the presence of sodium is almost twice as great as the initial concentration in the incubation medium. It is also obvious that in this sodium bicarbonate saline the other pentoses, D-ribose, L-arabinose and D-arabinose, have a final mucosal tissue concentration which is similar to the initial medium concentration of 6.66 mmoles. A tissue to medium concentration ratio (T/M) greater than 1.00 further exemplifies that D-xylose is the only pentose within this group which has been transported from the bathing medium to the mucosal tissue against its own concentration gradient. In a lithium bicarbonate saline medium, as shown in Table 1, D-xylose also is actively transported. There is, however, a reduction in this active transport, as indicated by its T/M ratio, which is less than that observed in the sodium medium ( $P > 0.02$ ). No change was seen with the other pentoses under this condition.

The active transport of D-xylose is not evident when potassium is substituted for sodium, the final concentration being  $5.01 \pm 0.32$  mmoles (seven animals) within the mucosal tissue. A T/M ratio of  $0.76 \pm 0.05$  further illustrates that the presence of a high potassium concentration in the incubation medium is inhibitory to the movement of D-xylose into the mucosa toward an equilibrium.

Table 1. PENTOSE TRANSPORT INTO RAT MUCOSAL TISSUE FROM A SODIUM AND A SODIUM SUBSTITUTED LITHIUM MEDIUM

Pentose	Na <sup>+</sup> bicarbonate saline medium		*T/M
	Number of animals	Final pentose conc. in mucosal tissue (mmolar)	
D-Xylose	12	12.64 ± 0.57	1.90 ± 0.09
D-Ribose	4	6.72 ± 0.40	1.01 ± 0.06
L-Arabinose	4	7.04 ± 0.15	1.06 ± 0.02
D-Arabinose	4	6.78 ± 0.70	1.02 ± 0.14
Pentose	Li <sup>+</sup> bicarbonate saline medium		*T/M
	Number of animals	Final pentose conc. in mucosal tissue (mmolar)	
D-Xylose	8	10.20 ± 0.71	1.53 ± 0.11
D-Ribose	4	6.67 ± 0.30	1.00 ± 0.05
L-Arabinose	4	7.02 ± 0.17	1.05 ± 0.03
D-Arabinose	4	7.16 ± 0.40	1.07 ± 0.06

In Tables 1 and 2, experiments were conducted over a period of 1 h at 37° C. The initial pentose concentration on both sides of the tissue was 6.66 mmolar. Volume of mucosal tissue water was not corrected for extracellular fluid volume. The S.E. of the mean is indicated for each result.

\* Ratio of final pentose concentration in mucosal tissue water to final pentose concentration in the mucosal incubation medium.

In the experiments involving sodium substitution, the question arose as to whether or not there is any sodium in the incubation media. Flame photometric analysis indicated that the sodium concentration after incubation within the mucosal and serosal fluids of the lithium bicarbonate saline were  $0.63 \pm 0.05$  and  $3.34 \pm 0.17$  mequiv./l. (four animals) respectively, and for the potassium bicarbonate saline,  $0.59 \pm 0.04$  and  $4.35 \pm 0.32$  mequiv./l. (four animals). Although the incubation media are not absolutely free of sodium, it seems unlikely, at the present time, that the extremely low concentrations of sodium present in the lithium medium after incubation play a part in the active transport of D-xylose.

Additional experiments were performed in order to compare the active transport of D-xylose in sodium and lithium bicarbonate saline. The data in Table 2 illustrate the effect of various inhibitors on this phenomenon. Active D-xylose transport in both the sodium and lithium media is inhibited by phlorizin, a competitive inhibitor of active intestinal sugar transport<sup>11-12</sup>, iodoacetic acid and sodium fluoride, inhibitors of glycolysis<sup>13</sup>; and 2,4-dinitrophenol, an uncoupler of oxidative phosphorylation<sup>14</sup>. It is interesting to note that oligomycin, an inhibitor of oxidative phosphorylation<sup>14</sup>, is very effective in inhibiting active D-xylose transport in the presence of sodium, but is not nearly as effective when sodium is replaced by lithium. This may be a reflexion on the mechanism of action of oligomycin in a lithium medium, because 2,4-dinitrophenol

Table 2. EFFECT OF VARIOUS INHIBITORS ON ACTIVE D-XYLOSE TRANSPORT BY RAT MUCOSAL TISSUE IN A SODIUM AND A SODIUM SUBSTITUTED LITHIUM MEDIUM

Inhibitor	Na <sup>+</sup> bicarbonate saline medium			*T M
	Conc. of inhibitor (mmolar)	Number of animals	Final D-xylose conc. in mucosal tissue (mmolar)	
None	—	12	12.64 ± 0.57	1.90 ± 0.09
Phlorizin	0.1	4	6.96 ± 0.17	1.04 ± 0.03
Iodoacetic acid	12.0	5	7.45 ± 0.16	1.12 ± 0.03
Sodium fluoride	12.0	6	7.13 ± 0.32	1.07 ± 0.05
2,4-Dinitrophenol	0.5	4	7.13 ± 0.32	1.07 ± 0.05
Oligomycin	0.026	8	7.43 ± 0.30	1.12 ± 0.05
Inhibitor	Li <sup>+</sup> bicarbonate saline medium			*T M
	Conc. of inhibitor (mmolar)	Number of animals	Final D-xylose conc. in mucosal tissue (mmolar)	
None	—	8	10.20 ± 0.71	1.53 ± 0.11
Phlorizin	0.1	4	6.23 ± 0.37	0.94 ± 0.06
Iodoacetic acid	12.0	4	6.80 ± 0.28	1.02 ± 0.04
Lithium fluoride	12.0	4	6.80 ± 0.12	1.02 ± 0.02
2,4-Dinitrophenol	0.5	4	6.43 ± 0.25	0.97 ± 0.04
Oligomycin	0.026	11	8.67 ± 0.14	1.30 ± 0.02

The experimental conditions were the same as those for Table 1. D-xylose and inhibitors were placed on both sides of the tissue. The initial D-xylose concentration was 6.66 mmolar. The S.E. of the mean is indicated for each result.

\* Ratio of final D-xylose concentration in mucosal tissue water to final D-xylose concentration in the mucosal incubation medium.

under this condition completely inhibits active D-xylose transport.

These experiments illustrate that the mechanism of active D-xylose transport by mucosa from rat jejunum is similar in either sodium or lithium bicarbonate saline. In addition, the energy requirements for this process are similar to those observed for the active intestinal transport of other sugars<sup>15,16</sup>. The fact that lithium can replace sodium in the incubation medium is the only apparent difference in the mechanism of active transport of this pentose and other sugars.

### Identification of Prostaglandin E<sub>2</sub> as the Principal Vasodepressor Lipid of Rabbit Renal Medulla

INVESTIGATORS in several laboratories have reported on the isolation of vasoactive lipids from renal medulla of several species<sup>1-7</sup>. Muirhead *et al.*<sup>1</sup> have separated these lipids into two classes: the antihypertensive lipids which prevent canine renoprival hypertension<sup>2</sup> and lower canine renal hypertension<sup>3</sup>; and the more acidic vasodepressor

Fig. 1.

lipids which acutely lower the blood pressure of the anaesthetized, vagotomized dog or rat treated with pentolinium<sup>4</sup>.

Hickler *et al.*<sup>5</sup> suggested that the acidic depressor lipids in extracts of renal medulla are prostaglandins<sup>6</sup>. In a similar study Lee *et al.*<sup>6</sup> separated two depressor lipids, one tentatively identified as PGE<sub>1</sub> (Fig. 1). The other depressor lipid differed chromatographically and was unable to stimulate non-vascular smooth muscle and was named "medullin". Subsequently, this material was identified<sup>7</sup> as PGE<sub>2</sub>-217 (now termed PGA<sub>2</sub> (ref. 10)). Strong *et al.*<sup>7</sup> also isolated vasodepressor lipids from rabbit renal medulla and interpreted their findings to indicate that their "purified VDL" was PGE<sub>1</sub>. They pointed out the possibility of the formation of "medullin" from PGE<sub>1</sub> by acid treatment and the similarity in the properties of "medullin" and PGE<sub>1</sub>-217 (PGA<sub>1</sub>) (ref. 11).

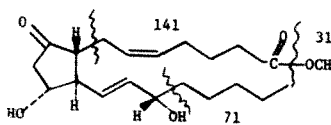

This communication concerns the identification of the acidic depressor lipids from rabbit renal medulla using less equivocal methods. Five kilograms of rabbit renal medulla were homogenized for 5 min in a Waring blender with an equal volume of water (pH adjusted to 7.0). After the addition of three volumes of acetone, the mixture was stirred and then allowed to settle overnight at 4° C. The insoluble residue was removed by filtration and the filtrate (75 per cent acetone) was concentrated *in vacuo* to an aqueous extract containing 10–20 per cent acetone. The solution, still at pH 7, was extracted twice with equal volumes of petroleum ether (boiling point 30°–60° C). The aqueous phase was adjusted to pH 3.0 with hydrochloric acid and extracted three times with 1/4 volume of methylene chloride. These three phases were combined and concentrated to approximately 1 l. The combined methylene chloride solution was extracted four times with 1/4 volume of 0.2 molar phosphate buffer, pH 8.0. After evaporation to dryness the methylene chloride layer provided the "neutral" fraction which was reserved for other studies. The aqueous buffer phase was acidified to pH 3.0 with hydrochloric acid and extracted three times with 1/3 volume of methylene chloride. After evaporation of the solvent, 0.35 g of acidic lipid fraction was obtained. All the activity detectable by the acute vasodepressor assay<sup>4</sup> was found in this acidic fraction.

Silicic acid chromatography<sup>7</sup> of pooled acidic lipids (984 mg) provided only two depressor fractions which were predominantly *E* (103 mg) and *A* (13 mg) prostaglandins. Thin-layer chromatography of the  $\text{PGA}_4$  fraction and subsequent elution with methanol from the silica gel<sup>12</sup> impregnated with silver nitrate plates indicated that  $\text{PGE}_2$  was the principal component of this fraction. The behaviour of this sample on thin-layer chromatography compared with an authentic sample and the conversion by alkali degradation to  $\text{PGB}_2$  (Fig. 1) were the signs used to identify this material.

Preparative thin-layer chromatography of 50 mg of the  $\text{PGE}$  fraction from the silicic acid column on a silica gel plate (20 × 20 cm) impregnated with silver nitrate 1 mm thick, developed with chloroform : methanol : acetic acid (CMA) (90 : 5 : 5), yielded 31 mg from the  $\text{PGE}_2$  zone on elution with methanol.  $\text{PGE}_1$ , if present at all, constituted less than 10 per cent of the  $\text{PGE}$  content of the renal medulla.

A portion of the  $\text{PGE}_2$  eluted from the chromatographic plate was esterified with ethereal diazomethane. The resulting methyl ester was shown by thin-layer chromatography and mass spectrometry to be identical to an authentic sample of  $\text{PGE}_2$  methyl ester (Systems MI, MII, MIII (ref. 13) (Table 1)). In still further confirmation of its identity another portion of the  $\text{PGE}_2$  was treated with alkali and converted to  $\text{PGB}_2$  which exhibits strong ultra-violet absorption at 278 m $\mu$  and has thin-layer chromatographic mobility distinguishable from that of  $\text{PGB}_1$ .

Table 1. MASS SPECTRAL DATA FOR  $\text{PGE}_2$  METHYL ESTER

						
<i>m/e</i>	<i>M</i> <sup>*</sup>	<i>M</i> -18	<i>M</i> -(2 × 18)	<i>M</i> -(18 + 31)	<i>M</i> -71	<i>M</i> -(18 + 71)
Per cent of base peak	366	348	330	317	295	277
	1.0	21.0	11.6	6.7	10.9	21.0
			<i>M</i> -(18 + 140*)	<i>M</i> -(36 + 140*)		
<i>m/e</i>			208	190		
Per cent of base peak			56.7	44.7		

\* Fragmentation involves hydrogen transfer.

In view of these findings it would appear that there is little doubt that the principal vasodepressor lipid of rabbit renal medulla is  $\text{PGE}_2$ . This is consistent with reports that the  $\text{PGE}_2$  precursor, arachidonic acid, is present in much larger quantities than the  $\text{PGE}_1$  precursor, dihomog- $\gamma$ -linolenic acid, in renal medulla<sup>14</sup>.

We thank Dr M. F. Grostic for the mass spectroscopy determinations and interpretations.

## IMMUNOLOGY

### Interferon and the Interaction of Allogeneic Normal and Immune Lymphocytes with L-cells

It has been supposed<sup>1-3</sup> that the effect of immune lymphocytes is connected with the transmission between the lymphocytes and target cells of the informative active parts. The destruction of homologous cells induced by lymphocytes is similar to the primary cytopathic effect in virus diseases. Nuclei of immune lymphocytes proved to exert the same destructive effect on target cells as that of intact immune lymphocytes<sup>2,3</sup>.

Our histochemical and autoradiographic investigations have demonstrated that cytoplasmic connexions ("bridges") containing DNA and RNA are formed between lymphocytes and target cells, and that H<sup>3</sup>-uridine-labelled RNA of lymphocytes and numerous granules containing DNA appear in the cytoplasm of L-cells. These processes are more marked with immune lymphocytes than with normal allogeneic lymphocytes of BALB/c mice<sup>4</sup>.

We consider it possible that interferon is produced in the course of immune lymphocyte target cell interaction; and that the interferon induced by virus should suppress that action of immune lymphocytes.

In experiments carried out with Dr. Inessa A. Svet-Moldavskaya, we attempted to detect interferon production in the course of interaction of immune lymphocytes BALB/c with L-cells. Interferon was tested by means of variola virus plaque formation in L-cells culture. All these experiments produced negative results. Investigation of virus interferon, however, revealed an unexpected result.

Continuous L-fibroblasts were used as target cells to which immune or normal lymphocytes from BALB/c mice were added (Rosenau and Moon's system<sup>5</sup>). BALB/c mice were immunized twice intraperitoneally with  $2.5 \times 10^6$  L-cells at an interval of one month, and one month later the mice were inoculated into the spleen with  $2.5 \times 10^6$  L-cells in 0.1 ml. Four days after inoculation the spleens were removed aseptically and made into a suspension in medium 199 by means of Potter's homogenizer. In the same way suspensions of cells were prepared from the spleens of non-immunized BALB/c. The cells were filtered and the numbers of live lymphoid cells were counted.

Interferon was obtained according to Hare and Morgan<sup>6</sup>. The chick embryo allantoic fluid containing Newcastle disease virus was irradiated with ultra-violet light until the complete loss of infectivity to chick embryos. The allantoic fluid of normal chick embryos was irradiated in the same way. Each of these fluids was diluted 1:20 with medium 199 and was then added to monolayer L-cell cultures. Cultured fluids from L-cells treated both

with irradiated fluid containing virus and irradiated normal allantoic fluid were collected separately after 48 h and acidified with 1 normal hydrochloric acid to pH 2. They were then kept at 4° C for 18 h and were neutralized with 1 normal sodium hydroxide to pH 7.5. The interferon preparation and the control fluid were treated similarly and then stored at 4° until use.

Our samples of interferon in the dilution 1:10 completely protect *L*-cells from the > 100 TCID<sub>50</sub> of encephalomyocarditis virus.

Interferon and the control fluid were added to the *L*-cells together with lymphocytes or 1 h after the incubation of lymphocytes with *L*-cells. In one experiment (No. 40), interferon was added to *L*-cells 1 h before contact with lymphocytes. In all the experiments, there were control tubes in which interferon and control fluid were added to the *L*-cell without any lymphocytes. The results of experiments were obtained by counting the number of live *L*-cells on the second or third day of incubation.

It is evident from Table 1 that the interferon did not suppress or destroy the *L*-cells. In the presence of interferon, however, normal lymphocytes affected *L*-cells in the same way as the immune cells, and thus the number of live *L*-cells was significantly reduced in the tubes to which normal lymphocytes *BALB/c* plus interferon were added (see Table 1).

Interferon did not enhance the sticking of lymphocytes to *L*-cells.

Holm *et al.*<sup>7</sup> and Möller and Möller<sup>8</sup> reported that non-immune allogeneic lymphocytes produced destruction of target cells when added to substances which agglutinated lymphocytes, in particular, with phytohaemagglutinin.

We studied the effect of phytohaemagglutinin in the system of *L*-cells plus lymphocytes from normal *BALB/c* and *C<sub>3</sub>H/f* mice.

Table 1. EFFECT OF INTERFERON IN THE SYSTEM OF *L*-CELL PLUS IMMUNE AND NON-IMMUNE ALLOGENEIC LYMPHOCYTES (*BALB/c*)

Experiment No.	Interferon with lymphocytes*		Control fluid in the presence of:		Interferon without lymphocytes	Control
	Immune	Non-immune	Immune	Non-immune		
51	7.5 ± 1.5	20 ± 3	19 ± 8	118 ± 8	141 ± 5.5	110 ± 31
40	104 ± 7	108 ± 14	102 ± 14	139 ± 14	—	—
59	nt	73 ± 10	nt	135 ± 13	238 ± 11.5	151 ± 10

\* In experiments No. 51 and No. 59 15 × 10<sup>6</sup> lymphocytes/tube were added; in experiment No. 40 2 × 10<sup>6</sup> lymphocytes/tube were added.

The agglutinating activity of phytohaemagglutinin proved not to be associated with its ability to destroy *L*-cells on contact with normal lymphocytes. The freshly diluted phytohaemagglutinin caused marked sticking of lymphocytes from normal *BALB/c* and *C<sub>3</sub>H/f* mice to *L*-cells and in both instances destruction of target cells was observed. The same phytohaemagglutinin diluted and stored for 2 months at 4°–8° C retained its haemagglutinating capacity but completely lost its capacity to cause death of *L*-cells when even large amounts of *BALB/c* or *C<sub>3</sub>H/f* lymphocytes (10 million/ml.) were added (see Table 2).

It is possible that the effect of lymphocytes on allogeneic cells in the presence of phytohaemagglutinin depends on the interferon formation. The induction of interferon by means of phytohaemagglutinin was described by Wheelock<sup>9</sup>.

The mechanism of the action of interferon in the system of normal and lymphocytes *L*-cells is obscure. Initially we made the assumption that normal lymphocytes trans-

mit some informative moieties to the other cells. Any impairment of information exchange between the lymphocyte and the cell leads to dysfunction and destruction.

It was shown recently in our laboratory that addition of methotrexate to the system normal *BALB/c* lymphocytes *L*-cells in a dose which was not toxic for these cells resulted in the destruction of *L*-cells by lymphocytes, as in the presence of interferon. Methotrexate did not increase the sticking power of lymphocytes to *L*-cells. It is possible that any agents which damage or denature lymphocyte DNA will act in the same way.

The cytological and cytochemical pattern of methotrexate and interferon in the system of normal lymphocytes target cells is similar to that with immune lymphocytes.

Blastoid transformation of lymphocytes appears to be close in its mechanism to the interaction of lymphocyte-target cell. It is possible that in blastoid transformation a portion of lymphocytes functions as donors and a portion of lymphoid cells as recipients of DNA. Transfer of the excess syngeneic DNA results in blastoid differentiation of cells. In other words, in both instances the same principal mechanism is hybridization but the final effects are different: cell differentiation or lethal morphogenesis resulting in death.

### Suppression of Viral and Chemical Carcinogenesis by means of Artificial Heterogenization

WE have demonstrated the possibility of artificial induction *in vivo* of viral antigens of the transplantation type in tumour cells. The antigens are induced by a chemical carcinogen, after intravenous or intracardiac inoculation of polyoma viruses, vacuolating virus *SV<sub>40</sub>* and adenovirus type 16 (refs. 1–3).

Administration of 7,12-dibenz-( $\alpha$ )-anthracene simultaneously with *SV<sub>40</sub>* or adenovirus, type 16, gave rise to tumours containing transplantation antigens of these viruses. Simultaneous inoculation of a chemical carcinogen and a mixture of two DNA viruses, polyoma and adenovirus 16, resulted in induction of tumours of which the cells contained transplantation antigens of both viruses<sup>4</sup>.

Based on these facts, the following two experiments to suppress chemical and viral carcinogenesis by artificial heterogenization were developed. (a) Newborn hamsters were inoculated with carcinogen and at the same time with *SV<sub>40</sub>* or adenovirus. When adult, these animals

were immunized with the corresponding virus. (b) New-born hamsters were inoculated with  $SV_{40}$  virus and adenovirus type 16. Adult animals were immunized with one of these viruses.

Vacuolating virus  $SV_{40}$  (strain A-426) was received from the Museum of Oncogenic Viruses in our institute. The virus was carried through three passages in green monkey kidney cell cultures. The titre of the virus was  $10^7$  TCID<sub>50</sub>/0.1 ml. Adenovirus type 16 was supplied by Dr R. S. Dreizin. Its titre was  $10^3$  TCID<sub>50</sub>/0.1 ml. when assayed in HeLa cell cultures at 7–8 days.

In experiments concerned with viral carcinogenesis, 0.1 ml. of virus was inoculated subcutaneously into the back of newborn hamsters (no older than 24 h). Another group of animals received 0.2 ml. of a mixture of  $SV_{40}$  and adenovirus 16 consisting of equal volumes of fluids containing viruses. In experiments concerned with the suppression of chemical carcinogenesis 7,12-dibenz-( $\alpha$ )-anthracene was dissolved in sterile apricot-kernel oil in a concentration of 1 mg/ml. The carcinogen was administered subcutaneously into the back of newborn hamsters in a dose of 60  $\gamma$ /0.06 ml. The first group received carcinogen alone; the second group received carcinogen and immediately after it  $SV_{40}$  virus in the same site ( $10^7$  TCID<sub>50</sub> in 0.1 ml.); the third group received carcinogen and immediately afterwards adenovirus in the same site ( $10^3$  TCID<sub>50</sub> in 0.1 ml.).

At the age of 1 month each litter in all groups of experimental animals, in experiments with both chemical and viral carcinogenesis, were divided into three subgroups. One subgroup was not immunized and the other two were immunized with adenovirus or  $SV_{40}$  virus, respectively. Immunization was given twice, on the thirtieth and forty-fifth day after birth, by intraperitoneal inoculation of 0.5 ml. of fluid containing the virus. Every 10 days the hamsters were palpated. The developing tumours were recorded and their percentage incidence in the surviving animals was calculated. Animals dying of other causes were excluded from the calculation. The data were then treated statistically.

	Total		2	10	10	9	31/49	63
	3 <i>SV</i> <sub>40</sub> + adeno 16	None	6	11	3	5	25/38	66
Experiment	4 <i>SV</i> <sub>40</sub> + adeno 16	Adeno 16	2	6	3	3	14/35	40
	5 <i>SV</i> <sub>40</sub> + adeno 16	<i>SV</i> <sub>40</sub>	2	1	1		4/37	11

\* Numerator: number of animals developing tumours; denominator: total number of animals inoculated.

Table 1 shows that viral carcinogenesis caused by administration of a mixture of two viruses,  $SV_{40}$  and adenovirus 16 was suppressed by vaccination both with  $SV_{40}$  alone and adenovirus alone, that is, carcinogenesis induced by  $SV_{40}$  may be suppressed in such circumstances by adenovirus type 16 which is practically non-oncogenic for hamsters. The difference between figures is statistically significant. Vaccination with adenovirus of hamsters inoculated at birth with  $SV_{40}$  alone produced no effect on the rate and frequency of tumour development. Tumours in animals inoculated with a mixture of  $SV_{40}$  and adenovirus 16 began to appear by 116–126 days. Immunization of these animals with  $SV_{40}$  or adenovirus 16 did not in any way influence the time of appearance of tumours, although the number of developing tumours was definitely reduced.

Table 2 shows that there was suppression of chemical carcinogenesis by artificial heterogenization. Immunization with adenovirus of hamsters inoculated at birth with carcinogen plus adenovirus resulted in a significant reduction of the number of tumours in comparison with those in the immunized subgroup. In this experiment, immunization also influenced the rate of tumour development. First tumours in non-immunized animals developed at 58 days, while the first tumour in animals immunized with adenovirus appeared much later on day 114.

In the next experiment, newborn hamsters were inoculated simultaneously with carcinogen and  $SV_{40}$  (Table 3). There was no difference in the time and rate of tumour development in groups of animals which were not immunized or in those immunized with  $SV_{40}$  and adenovirus. Animals receiving simultaneously carcinogen and  $SV_{40}$  showed marked stimulation of carcinogenesis in comparison with the animals receiving carcinogen only. The difference was not only in the incidence of developing tumours but also in the time of their appearance: first tumours induced by carcinogen plus  $SV_{40}$  appeared as early as 28 days after inoculation, while 7,12-dibenz-( $\alpha$ )-anthracene alone induced them only after 72 days. A stimulatory effect was manifest only in simultaneous administration of carcinogen and  $SV_{40}$ . Table 3 also shows that subsequent inoculation of  $SV_{40}$  and adenovirus to hamsters which at birth had received carcinogen alone did not influence the time of appearance and incidence of tumours.

Induction of viral antigens of the transplantation type during chemical carcinogenesis raises the question of whether individually specific antigens of tumours induced by chemical carcinogens are actually antigens of occasional passenger viruses.

Suppression of viral and chemical carcinogenesis by means of artificial heterogenization creates various poss-

## PATHOLOGY

### Bleeding Time and *in vivo* Platelet Adhesiveness in von Willebrand's Disease: Effect of Iontophoresis of Adenosine Diphosphate

MEASUREMENT of the adhesiveness of platelets *in vitro* has yielded variable results in von Willebrand's disease<sup>1-6</sup>. Hopes of increasing the discrimination between von Willebrand's disease and normal subjects using adenosine diphosphate (ADP) in an *in vitro* system have not been fulfilled<sup>2,3,6</sup>.

In patients with von Willebrand's disease, the *in vivo* platelet adhesiveness of Borchgrevink<sup>7</sup> has been measured in areas of the skin treated with ADP by iontophoresis<sup>8</sup>. A current of 2 m.amp/in.<sup>2</sup> at 90 V was passed for 5 min through a blotting paper pad, applied to the forearm, carrying 0.02M ADP in phosphate buffer pH 6.8. Contralateral control areas were iontophoresed with buffer only. After rinsing the site with buffer, a cuff at 40 mm of mercury was applied to the upper arm and three stab wounds 1 mm long and 3 mm deep were made in quick succession in each treated area. The wounds were lightly blotted every 15 sec to obtain the bleeding time, but this process was interrupted after the first two blottings to allow the outflowing blood to be sampled with a polythene automatic micropipette for platelet counts<sup>9</sup>. Blotting was resumed at 90 sec and continued until bleeding ceased, the end point being calculated from the mean of the three readings. Punctures apparently entering veins were rejected. Platelet counts<sup>10</sup> (about 200 cells) were made "blind", under phase contrast, in duplicate, in a random order and ignoring clumps because these were regarded as part of the haemostatic response. (Clumps were not seen in known samples of venous blood, which was always collected from an arm vein on the control side.) Platelet adhesiveness was given by the ratio (venous count - skin count)/venous count<sup>7</sup>. Factor VIII activities were measured on venous blood collected before iontophoresis, to avoid an adrenaline response to the procedure<sup>11</sup>, by a single stage assay based on the partial thromboplastin time<sup>12</sup>. Patients were diagnosed as suffering from von Willebrand's disease when they had: a history of haemostatic failure; close relations of both sexes who were also affected; a bleeding time >10 min; and a factor VIII level <45 per cent on at least one occasion. Results are shown in Table 1.

In normal subjects ADP increased the platelet adhesion and decreased the bleeding time. In von Willebrand patients the platelet adhesiveness was decreased, but the effects on the bleeding time were more difficult to interpret as six of the ten patients tested had bleeding times longer than 15 min and no end point was obtained. In those von

Bleeding times*						
Range of readings	—	2.9-7.8	2.5-6.8	—	4.7-12.0	8.0-15.0
No. of subjects	—	0	0	—	6	6

\* For normal subjects, the mean for the buffer site = 4.97 min and for the ADP site, mean = 4.37 min; mean difference (ADP-buffer) = 0.60 min (P < 0.01).

Willebrand patients with recordable bleeding times, however, three out of four showed lengthening of the bleeding time by ADP. Von Willebrand's patients could be distinguished from normal subjects irrespective of their factor VIII level at the time of testing. These results are shown in Fig. 1.

The arrest of bleeding from small wounds may usually depend on the interaction of ADP and thrombin<sup>13</sup>. It is likely, however, that ADP introduced into the skin would be broken down to AMP and adenosine<sup>14</sup>, and also other substances may be produced<sup>15</sup> which inhibit platelet aggregation<sup>16,17</sup>. If therefore there were a delay in thrombin generation, as might occur in von Willebrand's disease, a proportion of the iontophoresed ADP might already have degraded to inhibitory products. These might further impair the haemostatic response, accounting for the effects described. Preliminary experiments suggest that iontophoresis of partially degraded ADP will produce a von Willebrand like response in normal subjects.

I thank Dr G. I. C. Ingram for help in the preparation of this work. I also thank Dr K. M. Dormandy of the

Fig. 1. The effects of iontophoresis of ADP on the bleeding times and *in vivo* platelet adhesiveness of thirty-eight normal subjects and four patients with von Willebrand's disease. The differences between control and treated areas are plotted against each other; differences in *in vivo* adhesiveness on the ordinate; differences in bleeding time on the abscissa. ●, Normal subjects; ○, von Willebrand's disease (patients with bleeding times <15 min). Factor VIII levels on the four von Willebrand patients, measured at the time of testing and reading from right to left, were: 28 per cent, 131 per cent, and 55 per cent. The fourth patient (extreme left) had a factor VIII level of 13 per cent measured on a previous occasion, and this measurement was not repeated at the time of testing with ADP. The remaining six patients were not plotted as their bleeding times were all >15 min and end points were not recorded.

### Some Serum Protein Nitrogen Mustard Complexes with High Chemotherapeutic Selectivity

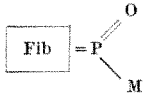

THE use of proteins as carriers of cytotoxic groups has been put forward on several occasions, based on indications that some specificity of uptake is thereby achieved. Busch and Greene<sup>1</sup> have shown that administration of radioactive albumin leads to the selective incorporation of radioactivity into tumours compared with other host tissues. Experimental evidence has also been advanced to show that radioactivity is localized selectively in tumours after administration of anti-fibrin antibody labelled with iodine-131 (ref. 2) and of similarly labelled fibrinogen<sup>3</sup>. This effect was more marked in the case of transplantable tumours than for spontaneous tumours but the results obtained provide a sound experimental basis for the use of this protein as a vehicle for the preferential introduction of cytotoxic agents.

Several years ago, we reported some preliminary experiments on the use of albumin as a carrier of latent cytotoxic groups<sup>4</sup>. No anti-tumour activity was apparent in the assessment of this compound, but dose levels used were far below toxic. It was considered at that time that macromolecules containing a more reactive cytotoxic group would not be very likely to be effective because of intramolecular alkylation with consequent loss of activity. Discussions with Dr B. Larsen (Aarhus) in connexion with his experiments with albumin and melphalan, some results of which have been reported recently<sup>5</sup>, indicated that the use of relatively highly reactive cytotoxic groups might be feasible. Our own experience with polyamino-acid carriers has confirmed this (unpublished work).

We wish to report preliminary data on the use of fibrinogen and two other proteins as carriers of reactive and latent cytotoxic groups. Bovine fibrinogen (Armour) was treated in buffer (pH 8.0) with di-2-chloroethyl-phosphoramidic dichloride to introduce latent cytotoxic groups in which the nitrogen mustard is deactivated by virtue of being linked by a phosphoramidate bond. As a more reactive species, *N,N*-(di-2-chloroethyl)phenylenediamine was coupled to the protein using a water soluble carbodi-imide [1-cyclohexyl-3-(2-morpholinoethyl)carbodi-imide metho-toluene-p-sulphonate].

As control compounds, protein was stirred in buffer with *N,N*-di-(2-chloroethyl)-phenylenediamine in the absence of carbodi-imide to see whether the nitrogen mustard base

\* M = -N(CH<sub>2</sub>CH<sub>2</sub>Cl)<sub>2</sub>.

† Supernate fraction after stirring CB 3212 24 h, in buffer.

could be conjugated to protein without the actual formation of a covalent bond. The modified protein was in each case dialysed against 0.2 per cent sodium citrate solution before freeze drying. Coupling was also effected by the use of diazotized *N,N*-(di-2-chloroethyl)phenylenediamine (ref. 6). In this case the product was precipitated from the buffer solution almost immediately and was separated by centrifugation. In addition to fibrinogen itself, an alanylated product was also modified in the hope of obtaining products of greater water solubility<sup>7</sup>. Alanylation was carried out by treating fibrinogen in phosphate buffer, pH 7, with a solution of *N*-carboxyanhydro-DL-alanine in dioxan. After dialysis to remove polyalanine, the product was freeze dried. Analysis showed that about 65 per cent of the lysine ε-amino groups had been modified with DL-alanyl side chains of average length nineteen residues.

Compounds were analysed for amino-acid content, chlorine and alkylating power as measured by the Epstein technique<sup>8</sup> suitably modified for this type of compound. It was found that values for nitrogen mustard content

calculated from the latter two parameters agreed within the limits of experimental error, indicating that the chlorine present in the substance was still covalently bound and was not present as an associated hydrolysis product.

The compounds were tested for inhibitory potency on the *ADJ/PC6A* plasma cell tumour<sup>9</sup> in mice using an assay system similar to that previously described for the *ADJ/PC5* tumour<sup>10,11</sup>. Female *BALB/C* mice were implanted subcutaneously by trocar, and after 10 days a suspension of the protein derivative in oil was injected intraperitoneally at a wide range of dose levels. After a further 10 days the tumours were dissected out and weighed. The  $ID_{90}$  (90 per cent inhibitory dose) was the dose required to reduce tumour growth to 10 per cent of that of the controls, and the ratio  $LD_{50}/ID_{90}$  was the therapeutic index.

Considering first the phosphoramidate mustards (*CB* Nos. 3212, 3498/B, 4392 and 3495), it would appear that coupling with fibrinogen or its alanylated derivative produced no increase in effectiveness. The derivatives of the chemically more reactive *N,N*-di-2-chloroethylphenylenediamine, however, gave results which were of considerably greater interest. The derivative of fibrinogen itself (*CB* 3494) was of the same order of effectiveness (as measured by therapeutic index) as the acetyl derivative (*CB* 1134) of the base, but if alanylated fibrinogen was used (as in *CB* 3496) the index rose by a factor of 6–120.

Somewhat surprisingly, the two derivatives in which the base was not covalently bound to protein (*CB* 3524 and 3525) also showed a high degree of anti-tumour activity being several times more effective than the free compound (*CB* 1128). An Epstein determination showed that the mustard had lost none of its alkylating ability during the protein treatment in buffer and so apparently had neither alkylated the protein nor been hydrolysed. The potentialities of this particular mode of protecting chemically highly reactive compounds and the mechanism whereby it is achieved have yet to be fully elucidated.

Modifications were also carried out in which human albumin and human gamma globulin were alanylated and coupled using carbodi-imide. The resulting compounds (*CB* 3527–3530) have not yet been examined to the limit of their inhibitory potencies, but the data obtained indicate a high degree of anti-tumour effect.

## PHYSIOLOGY

### Individual Differences in a Physiological Effect of Water Restriction in Rats

WHEN their water intake is restricted, rats will learn to run a maze or press a bar to obtain water. Individual rats learn these tasks with varying speeds, and there are many factors which can contribute to speed of learning and hence to differences between individuals. Among these is the possibility that the same amount of time spent without water does not arouse the same "need" for water in different animals. A "need" for water arises at least in part from the dehydration of body tissues and this is in turn reflected by a fall in body weight which is larger than can be accounted for by the concurrent fall in food intake<sup>1</sup>. There is little information on changes in body weight consequent on water restriction schedules in different animals. The experiments reported here were concerned with estimating the effect of a standard schedule of water restriction on the body weight of rats varying in age, sex or strain.

Rats (Glaxo hooded and Sprague-Dawley) were fed powdered food *ad lib*. (Wyatt GR/R/3: crude protein, 18.8 per cent; oil, 2.1 per cent; crude fibre, 3.1 per cent) and were housed in pairs at 24°–26° C. Body weight, food and water intake were recorded daily at about 10.30 a.m. During periods of water restriction, water bottles were available only between 4.00 p.m. and 5.30 p.m. In addition to water intake during this time the animals obtained about 1.5 ml. water, as 0.1 ml. rewards, in a bar pressing apparatus.

Fig. 1 shows that adult rats who had reached a stable body weight and young growing rats lost the same absolute amount of weight (about 18 g) when placed on a 22.5 h water restriction schedule. The young rats continued to grow during the restriction period. When restriction ended, both groups put on the same amount of weight as they had lost at the start. Changes in body weight followed the same pattern on subsequent short water restrictions and the amounts of water lost and regained were the same as on the first occasion.

Because adult and young rats lost the same absolute amount of weight it follows that the young rats, being lighter initially, lost more as a percentage of initial weight.

Fig. 1. Mean body weight of male rats submitted to a schedule of water restriction at different ages. Adult rats (●—●) were first water restricted at 245 days of age and young rats (●---●) at 59 days of age. Water was available for 1.5 h each day. Both groups lost about 18 g each time water restriction was imposed and regained this weight when restriction ended.  $n = 4$  in each group.

Table 1. BODY WEIGHT OF MALE RATS FOLLOWING WATER RESTRICTION  
Results are expressed as a percentage of initial weight

				167	244.63	92.19	0.89	329	324.50	93.30	1.35

Table 1 shows body weight changes of groups of male hooded and Sprague-Dawley rats on successive water restrictions expressed as a percentage of initial body weight. The two strains grow at different rates, Sprague-Dawley growing faster. At the same initial body weight (though necessarily different age) changes in body weight were similar for the two strains. At the same age, however, hooded rats, being smaller, fell to a lower percentage of their initial body weight.

Comparisons can also be made between sexes (Tables 1 and 2): at an initial body weight of about 231–235 g male rats lost more weight (in terms of percentage loss) than Sprague-Dawley females whether they were older (male hooded) or younger (male Sprague-Dawley). The corresponding figure for female hooded rats agrees with these results. The variability was usually higher for the female animals which suggests that the effect of water restriction may be reflected differently, on the body weight measure, in females at different stages of the oestrous cycle.

Table 2. BODY WEIGHT OF FEMALE RATS FOLLOWING WATER RESTRICTION  
Results are expressed as a percentage of initial weight.

Sprague-Dawley				Hooded (young)			
Age (days)	Initial	Body weight %	S.D.	Age (days)	Initial	Body weight %	S.D.
83	168.63	91.69	1.81	89	157.0	91.40	1.22
111	231.13	95.70	1.48				
125	245.25	94.18	3.47				
139	252.63	95.52	4.43				
167	258.88	94.51	1.14				

The percentage figures shown in Tables 1 and 2 were obtained by taking the lowest body weight occurring during the restriction period and expressing this as a percentage of the body weight on the morning preceding

water restriction ("initial" body weight). Similar results were obtained when body weights on the 3 days following water restriction were expressed as a percentage of the three preceding days.

Groups of hooded rats first placed on the restriction schedule at different stages of growth were compared with a group of unrestricted controls of the same age (Fig. 2). The group of rats restricted during the period of faster growth, from 59 to 78 days, grew faster during water restriction than the rats restricted later, from 83 to 103 days. At the age of 174 days and after a total of five periods of restriction, there was no difference in body weight between these groups. Comparison with the unrestricted control group shows that water restriction does not interfere with the rate of growth. The apparently greater body weight of the restricted groups at 174 days is of no significance because the control rats, which had been matched for body weight at 50 days, developed into smaller animals. Such a difference in growth rate is not unexpected<sup>2</sup>. The restricted animals had simply maintained at 174 days the body weight advantage they had over the controls at an earlier age.

Thus the physiological consequences of the same water restriction schedule differ in individual animals. Age, sex and strain of animals of the same species may all influence the extent of loss of body weight following the same water restriction schedule. Our results, as well as considerations of diet composition<sup>3</sup>, may help to interpret discrepant results obtained from different types of rats in experiments on motivational factors<sup>4,5</sup>.

## Potentials measured from Glycerinated Cardiac Muscle

SZENT-GYÖRGYI<sup>1</sup> has shown that muscle extracted in glycerol serves as a model for the actinomyosin contractile system. He found that molecular orientation is well preserved and that the contractile process can be investigated in the presumed absence of a functioning cell membrane. The contractions of glycerinated fibres from skeletal, cardiac and smooth muscle induced by ATP have since been studied by several workers. Chichibu<sup>2</sup> showed that the resting membrane potential of the extensor muscle of the American freshwater crayfish is decreased by glycerol. 2 molar glycerol reduced the membrane potential from  $-80$  mV to less than  $-20$  mV within 3 h, but fibres kept in glycerol for more than a few hours were not studied.

Nayler and Merrillees<sup>3</sup> stated that a transmembrane resting potential persisted in the glycerinated ventricular muscle of the toad, and ranged from  $-37$  mV to  $-44$  mV in muscle extracted in 50 per cent glycerol for 3 weeks, and from  $-30$  mV to  $35$  mV in muscle extracted for 6 weeks. They suggested that, if these results were interpreted in accordance with the ionic hypothesis of cellular electrical activity<sup>4</sup>, some functional activity must persist in the plasma membrane of glycerinated cardiac muscle. This would make tenuous previous work using muscle extracted in glycerol as a contractile protein model.

We made the investigation reported here to determine whether the potentials described by Nayler and Merrillees represented true transmembrane resting potentials.

The potential difference between modified Tyrode solution<sup>5</sup> and glycerol-Tyrode solutions containing glycerol in concentrations from 0.25 to 50 per cent was measured (Fig. 1). The two solutions were connected through a Tyrode-agar bridge and the difference between the potentials measured through glass capillary microelectrodes filled with 3 molar potassium chloride. Electrodes *D* and *E* in Fig. 1 were first placed in the modified Tyrode solution (*B*), and differences in tip potential eliminated. Then electrode *D* was transferred to the glycerol-Tyrode solution (*A*), and the potential difference between the electrodes measured. In this apparatus four junctions were measured: Tyrode-glycerol; potassium chloride-glycerol; potassium chloride-Tyrode; and Tyrode-Tyrode. In measuring potentials from a preparation of glycerinated fibre (Fig. 2), three junctions are measured when one microelectrode is placed within the fibre and another in the surrounding bath: Tyrode-glycerol; potassium chloride-glycerol; and potassium chloride-Tyrode. Thus the measuring system in Fig. 1 duplicates the junction potentials measured in the preparation of glycerinated fibre except that it contains a Tyrode-Tyrode junction, which should be insignificant, and that it lacks the junctions between the glass capillary microelectrodes filled with 3 molar potassium chloride and the colloid substances contained in the glycerinated fibre. No significant junction potentials were found between the Tyrode and glycerol solutions.

Glycerinated strips of dog ventricular muscle were prepared and stored in 50 per cent glycerol at  $-20^{\circ}\text{C}$  for 1-7 months. Benson and Hallaway<sup>6</sup> noted no change in the contractile properties of similarly prepared muscle bundles stored for 6 months. The resting potential of fresh cardiac muscle is  $-90$  mV, and we recorded potentials in the range of  $-32$  to  $-56$  mV from the glycerinated cardiac fibres, with an average of  $-46$  mV. There was no significant change in the recorded potentials with time. The resistance of the microelectrode invariably increased two to three times when the tissue was impaled.

No change occurred in the measured potential when Tyrode solution containing 25 mmolar or 45 mmolar potassium chloride was substituted for control Tyrode (potassium = 2.7 mmoles/l.). Substitution of Tyrode solution containing 1.35 mmolar calcium chloride or no

Fig. 1. Petri dish *B* contained the modified Tyrode solution. (1) Represents a Tyrode-glycerol junction, (2) a potassium chloride-glycerol junction, (3) a potassium chloride-Tyrode junction and (4) a Tyrode-Tyrode junction.

Fig. 2. *A* represents the bathing modified Tyrode solution, *B* the fibre containing glycerol and *C* and *D* microelectrodes. (1) Represents a Tyrode-glycerol junction, (2) a potassium chloride-glycerol junction and (3) a potassium chloride-Tyrode junction.

calcium chloride for the control Tyrode (calcium = 2.7 mmoles/l.) failed to affect the measured potential, as did the addition of epinephrine (0.01-0.06 mg/ml.).

Stimulation of the glycerinated fibres extracted for 1 month, while a potential of  $-50$  mV was being recorded, using rectangular pulses of up to 30 V which lasted up to 100 msec, produced no change in the potential.

Addition of ATP to the concentration of  $4 \times 10^{-3}$  moles/l. caused those glycerinated fibres which had been stored for 7 months to contract, but did not affect the measured potential of  $-48$  to  $-52$  mV.

The surface of glycerinated cardiac muscle which had been stored for 3 months was scraped with the blade of a scalpel. The average potential measured from these abraded areas was  $-28$  mV. Recordings from pulverized cat papillary muscle stored for 3 months were in the range of  $-24$  mV.

A difference in potential similar to that described by Nayler and Merrillees was found between glycerinated cardiac fibres and the extracellular bathing solution, and it was shown that a significant junction potential does not exist between glycerol and Tyrode solution. Bergen and Terroux<sup>7</sup> showed that in mammalian atria an increase in extracellular potassium ions results in depolarization, but increasing the extracellular concentration of potassium chloride did not affect the potential measured from glycerinated cardiac muscle. Hoffman and Suckling<sup>8</sup> showed that severe depletion of extracellular calcium causes a marked decrease in the resting potential of Purkinje fibres. The potential difference measured from glycerinated cardiac muscle did not change even when calcium was removed from the extracellular solution; nor did addition of epinephrine change the potential obtained from glycerinated cardiac fibres. Furthermore, procedures that would surely damage and destroy a cell membrane, such as scraping the surface of a fibre or pulverizing a muscle bundle, did not abolish the potential recorded from the glycerinated muscle. Thus the potential measured from the glycerinated cardiac muscle does not behave like a true transmembrane resting potential. Our observations show that contraction of glycerinated cardiac fibres is induced by ATP independently of any effect on the potential recorded from the tissue. There was therefore no demonstrable action of ATP at the membrane site analogous to excitation. The relatively free access of ATP to the interior of the cell strongly suggests that there is no significant differential permeability of the remnant of plasma membrane with respect to the small ions such as potassium, sodium and chloride. Such differential permeability is a prerequisite for the existence of the membrane potential<sup>9</sup>.

The nature of the potential measured is uncertain. The invariable increase in electrode resistance suggests an interaction at the electrode tip between the colloid components of the glycerinated tissue and the glass or 3 molar potassium chloride. The absence of a significant junction potential in the system of Tyrode solution and glycerol in water suggests that some component of tissue is necessary.

## Sodium Extrusion by Giant Muscle Fibres from the Barnacle

THE neuromuscular physiology of giant muscle fibres from the barnacle has been described in some detail by Hoyle and Smyth<sup>1</sup>. Single striated muscle fibres up to about 2 mm in diameter have been found. Such fibres have cross-striations similar to those of vertebrate skeletal muscle cells and maintain an internal electrical negativity of from -74 to -80 mV.

In our laboratory, we have found the average intracellular content of sodium of freshly isolated single giant muscle fibres from the barnacle, *Balanus nubilus*, to be 15 mmoles/kg fibre (Table 1), which agrees with the measurements of Brinley<sup>2</sup>. Also measured and presented in Table 1 are the contents of potassium and water of isolated single fibres. If the intracellular sodium is uniformly distributed in the cell water, the internal concentration must be about 20 mmoles/l. The external sodium concentration is about 470 mmoles/l., so the electrochemical theory for passive ionic fluxes<sup>3</sup> predicts that the influx of sodium is about 500 times greater than its efflux. To maintain a steady state with the low internal concentration of sodium, it is evident that, like vertebrate skeletal muscle fibres, the fibres of the giant barnacle must actively transport sodium out of the cells by a process coupled to cell metabolism. The finding<sup>2</sup> of a strophanthidin sensitive and saturating component of sodium efflux is consistent with this conclusion.

The purpose of the work presented in this report was to provide a direct demonstration that giant muscle fibres from the barnacle can produce a net extrusion of sodium ions against an electrochemical gradient. It is well known that vertebrate skeletal muscle fibres can extrude sodium in the presence of external potassium after they have been enriched with sodium<sup>4</sup>. In these conditions, the extruded sodium is replaced with potassium.

We applied methods similar to those used to demonstrate extrusion of sodium in skeletal muscle fibres. Small bundles of barnacle giant fibres were carefully isolated

and stored for 16 h at 4° C in a potassium-free medium of the following composition: Na<sup>+</sup>, 465 mmolar; Ca<sup>++</sup>, 25 mmolar; Mg<sup>++</sup>, 8 mmolar; Cl<sup>-</sup>, 533 mmolar; SO<sub>4</sub><sup>=</sup>, 4 mmolar; *tris* buffer, 5 mmolar (pH = 7.6). At the end of the period of sodium enrichment, single fibres were carefully isolated from the bundle for analysis for sodium and potassium. The remaining bundles of fibres were then transferred to a medium containing potassium ions at a concentration of 10 mmolar; the other ions were present at the concentrations given previously. These bundles were kept in the solution containing potassium for 6 h at 20° C. At the end of this period, single fibres were again isolated and prepared for sodium and potassium analyses. The cation analyses were performed by flame photometry after ashing the fibres in platinum crucibles at 550° C for 10 h. Before ashing, all fibres were rinsed for 10 min in a solution with the sodium and potassium removed and replaced with an osmotic equivalent of sucrose, to wash away any extracellular sodium and potassium adhering to the fibres.

The results, which are given in Table 2, show that, on the average, the fibres recovering in the medium which contained potassium have extruded 12 mequiv. of sodium/kg of muscle and gained 15 mequiv. of potassium/kg of fibre. The net outward extrusion of sodium has obviously taken place against an electrochemical gradient because the outside concentration of sodium is more than ten times the magnitude of the intrafibrillar concentration and the fibres maintain an internal electrical negativity.

The process which actively transports sodium in vertebrate skeletal muscle cells is known to be inhibited by the drug strophanthidin<sup>5</sup> and Brinley<sup>2</sup> has observed a strophanthidin sensitive portion of sodium efflux in barnacle giant muscle fibres. It should therefore be possible to abolish the net sodium extrusion which takes place in isolated barnacle fibres by application of strophanthidin. The procedure followed was identical to that used to demonstrate extrusion except that the recovery medium containing potassium also contained 10<sup>-6</sup> molar strophanthidin. The results are shown in Table 3. It is clear that strophanthidin has prevented the sodium extrusion and potassium gain which takes place in its absence. Fibres in the

recovery medium containing strophanthidin continued to gain some sodium and lose some potassium. All the results reported are statistically significant at the stated levels.

It is interesting that strophanthidin prevented the gain of potassium as well as the extrusion of sodium. The inward movement of potassium ions to replace the extruded sodium ions must be in some way linked with the mechanism for transporting sodium ions outwardly. Keynes *et al.*<sup>6</sup> have shown that, in vertebrate skeletal muscle, the inward potassium movement during recovery may be in the direction of or against the electrochemical gradient for potassium ions, depending on the conditions. The nature of the inward potassium movement during recovery of barnacle giant muscle fibres from the sodium-rich state is now being investigated in this laboratory.

## GENERAL

### Biological Entropy Pump

THE recent exchange between Woolhouse<sup>1</sup> and Popper<sup>2</sup> presents the enigma of the low entropy content of living systems. The means whereby their rapid decay into the inert state of "equilibrium" is avoided are serious problems to the theoretical biologist. It is, of course, to Schrödinger<sup>3</sup> that we owe the classic analysis of biological entropy. It was the source of negentropy which Schrödinger was unable to discover, as the recent discussion indicates. That from one generation to the next, a complex coding and decoding can occur without net loss of negentropy is problem enough, but in the large sequence of generations through geological time, we see that, if anything, the informational system becomes fuller and the organization of many species more improbable. It is my purpose here to show what I believe to be the answer to this seeming paradox and to describe the "entropy pump" whereby the species of living matter not only prevent a drop into a position of greater positive negentropy at each generation, but may in fact acquire more negentropy as their reproduction continues. This will involve only principles widely known and easily defended.

From the second law of thermodynamics, we learn that at temperatures above absolute, chemical change always proceeds, in a statistical system, from states of lower to higher entropy. Put in a biological reference we might express it thus: if a female codfish lays a million eggs, these eggs (considered en masse) will show the expected degradation and the egg genomes will have an average entropy content higher than the original egg genome of the parent. Very few generations of such deterioration can be envisaged as compatible even with the continuance of life. Yet we know that such a succession of generations of nearly infinite extent precedes our hypothetical drama. The ace in the hole, so to speak, is that in such a system as the million eggs from one parent, the entropy content

Fig. 1. The "entropy pump" as illustrated by the hypothetical distribution of entropy content of the genomes of 1,000,000 eggs produced by one codfish. The entropy content of the maternal genome is indicated by  $E_m$ . The mean entropy content of the genomes of the eggs is denoted by dotted line  $E_f$ . A marks area where egg genomes have entropy lower than or equal to that of the parent.

of the individual genomes may be expected with certainty to distribute in a simple fashion about a mean value which by the dictates of the second law must be of a higher value for entropy than that of the original egg genome. In such a set we might suppose that, in perfect consistency with the second law, one tenth of 1 per cent or some such low proportion of the eggs actually has a genome with an entropy content equal to or less than that of the parental egg (Fig. 1). These remarkable ones are most likely to grow up and repeat the reproductive process. It will be seen that this is but a re-statement of the mechanism of natural selection, fully consistent with the meaning of the term as used by Darwin and as still used by our contemporaries.

This simplification does clarify one point which has perhaps not been sufficiently stressed in statements of evolutionary mechanisms. For this I suggest the term "chemical selection" to denote the very intense selection which goes on in such a clutch of eggs long before the "survival of the fittest" exerts its statistical leverage. Many of the eggs would not hatch because, as they are at the high end of the entropy distribution, they have such serious defects as the lack of some essential enzyme which crosses them out of the survival race at the starting gate. When we consider that mammalian sperm frequently show 10 per cent morphological abnormalities, the reality of this chemical selection may be appreciated. Selection at this molecular level has been discussed previously by Lima-de-Faria<sup>4</sup>, although in a context apart from the present one. It has also been appreciated by Whyte<sup>5</sup> as "internal selection".

One might be tempted to the view that such an "entropy pump" would be a characteristic of living processes and might indeed furnish a definition to distinguish the living from the non-living world. Since the advent of subcellular biology and of the molecular approach to life processes, it would be gratifying to differentiate the world of living things from that of the non-living with such a succinct criterion. The note of Spiegelman *et al.*<sup>6</sup> extends the process of chemical selection down to the adaptation of enzymes, thus raising the question of the propriety of defining life only with reference to cellular processes. There seems to be little objection to the hypothesis that life preceded the evolution of cellular structure and that subcellular mechanisms may show replicative or reproductive processes. The differentiation of the living from the non-living may perhaps be made on the basis of such an "entropy pump".

## BOOK REVIEWS

### PROBLEMS WITHOUT INSIGHT

#### Major Problems in Developmental Biology

Edited by Michael Locke. (25th Symposium of the Society for Developmental Biology.) Pp. x+408. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.) 128s.

THIS anniversary volume celebrates publication of the twenty-fifth symposium of the Society for Developmental Biology. What has developed in developmental biology during this period? For one thing, a new view has appeared, and seems now to generally prevail, to wit: "Differentiation (is) the outward sign of selective gene action . . . We shall make use of . . . the increasingly plausible concept . . . that superimposed on the basic template principle . . . there are control mechanisms." (James Ebert and M. E. Kaighn, second chapter of the present volume.) That development constitutes the orderly, sequential turning off and on of the right genes in the right places at the right times is a proposition which few would contest today. The central questions of developmental biology are: How are genes repressed? How are they turned off and on? and How does the programming of gene expression work? These questions, which lie at the heart of developmental biology, are not dealt with in the present volume. *Major Problems in Developmental Biology* deals rather with the new descriptive embryology, the fact that different specialized cells have different enzymes, respond to different media with different growth patterns, are differently affected by hormones, and so on. It may well be that hidden in this wealth of descriptive material of different developmental systems is the system which, by its study in depth, will reveal a new central principle or principles about how development works. One cannot today point to that system.

*Major Problems in Developmental Biology* is none the less not to be sneezed at as a book to read. The introductory chapter by Jane Oppenheimer, a "what were they doing 25 years ago?" kind of chapter, is wonderful. Holtfreter was studying the development of pieces of gastrulae; Harrison, induction by the neural crest; and Brachet, the number and location of sulphhydryl groups in developing amphibian embryos. Change was, however, just around the corner. Beadle, Ephrussi and Tatum were shortly to establish biochemical genetics and hence molecular biology, and then Ebert's and Kaighn's present formulation of developmental biology. The second chapter, by James Ebert and M. E. Kaighn, is a thorough review of modern work of development on the cellular level, and even to some extent on the molecular level. "Are there cases of differential DNA replication other than that which has to do with the nuclear organizer?" they ask—a good question and one that deserves to be settled. Great emphasis is placed, too, on the numerous cases of which we now know in which DNA replication is the prerequisite to change of gene state from repressed to derepressed, or vice versa. A third chapter by E. Hadorn reviews his work on determination as studied with fragments of imaginal disks of insect larvae, which can grow apparently for ever as cell cultures in the abdo-

men of adults, but which will differentiate briskly if transplanted to a larva. C. H. Waddington discusses fields and gradients, a subject obviously not to his taste, while J. P. Trinkhaus reviews morphogenetic cell movements, coming to the conclusion that there are many unsolved problems in this field. So far as the aggregation of similar cells out of a mixture of dissimilar cells, Trinkhaus votes for selective adhesion of like cells. H. Ursprung in "Patterns of Development" comes to the conclusion that it may well be that all patterns flow from the amino-acid sequences of proteins, and thus directly from nucleotide sequence in the gene. Maybe so—but it's a long step from nucleotide sequence to patterns in butterfly wings or banding of feathers. D. E. Koshland and M. E. Kirtley bring a new discipline, protein chemistry, to the Society for Developmental Biology. They develop a new general theory of control of gene and cell activity. On the level of transcription, Koshland and Kirtley propose that a polynucleotide, presumably the product of the specific DNA sequence involved, is bound covalently to a protein, possibly also the product of that gene, which in addition contains an appropriate binding site for a small effector molecule. They do not specify how such an RNA protein molecule by binding specifically to the gene in question would cause that gene to be repressed so far as transcription is concerned.

Anton Lang next takes up the new knowledge of the action of plant hormones. Thus, it is now clearly established that for gibberellic acid to exert its effect by increasing the rate of plant cell elongation, DNA synthesis must first occur. Induction of cell elongation by indole-acetic acid, a second plant hormone, does not require this intermediate step. Nature is clearly telling us something here, but we do not yet understand her message. Interestingly enough, the influence of gibberellic acid on the aleurone layer of the barley endosperm, an influence which causes the *de novo* production of  $\alpha$ -amylase and other hydrolytic enzymes, does not appear to require DNA synthesis. J. W. Saunders and J. F. Fallon review cell death, and point out that many cells die in the course of and as a part of normal development. Cell death in early developmental stages is therefore apparently genetically pre-programmed. H. Rubin discusses in detail contact inhibition and the loss of contact inhibition in the transformation of tissue culture cells to cancer cells *in vitro*. Rubin believes that contact inhibition is caused because the cultured cells prefer to stick to the culture dish rather than to each other, and that loss of contact inhibition is caused by loss on the part of the cells of their affinity for the culture dish. He further suggests that transformation is caused by some sort of self-perpetuating change in the affinity of cell membranes for things like the bottoms of culture dishes. His suggestion should be a testable one.

Finally, and this is a new direction for the Society for Developmental Biology, Marcus Jacobson, in a long and interesting chapter, discusses "starting points for research in the ontogeny of behavior". This important new direction is certainly one still appropriate for study by descriptive methodologies.

*Major Problems in Developmental Biology* does not therefore really state or encompass the central principal problems of the subject. It does none the less provide an evening of pleasant reading. JAMES BONNER

### WHAT SCIENCE EXPLAINS

#### Completeness in Science

By Richard Schlegel. Pp. xi+280. (New York: Appleton-Century-Crofts, a Division of Meredith Publishing Company, 1967.) \$7.50.

As the tide of protest against scientism slowly gathers momentum it is very important that a number of funda-

mental questions about science should be asked in the spirit which is commonly claimed by, and often manifested in, scientists themselves—dedication, caution, and humility. Professor Schlegel's approach admirably fulfils this first condition. These questions are about science and so they are philosophical questions—or if you prefer, metascientific; but not, if you please, "the science of science", a phrase that any mediaeval schoolman would have pounced on as failing to employ a term univocally. But the questions are about science; and because science, as commonly understood, is involved in action, only actors in the drama are likely to possess the insight necessary for an accurate appraisal of the content of scientific knowledge. It is thus to scientists themselves, standing back in philosophic detachment, that we must look for answers to these questions. Unfortunately, the last "scientist" appears to have been Aristotle; today we have (on the most optimistic view) only "physicists", "chemists" (said to be approaching extinction) and "biologists". Further progress in fundamental physics seems likely to turn as much on philosophical insight as on particle accelerators, thus it is not surprising that the majority of scientists approaching these philosophical problems are physicists. "Nothing is here for tears", providing that "physics" is not tacitly (less often blatantly) regarded as coextensive with "science". Professor Schlegel (whose exposition of the physical aspects of the questions conveys to me a sense of deep understanding but whose accuracy in detail I am not competent to assess) explicitly repudiates (page 5) any such claim; a slight relapse (page 249) does not seem to have coloured his final judgment. A mere outline of Schlegel's book would be mainly a recitation of the obvious problems that arise in relation to the central question, hence such exposition as is necessary may be combined with critical comment. This procedure is all the more necessary in view of my suspicion that an error of strategy has been committed that to some extent reduces the impact of an otherwise very timely and accomplished piece of work.

I have referred at the beginning of this review to a "number of questions" whereas the author appears to ask only "How Completely Science may Describe the Universe", which is his sub-title. But the first chapter is headed "The Problem of Completeness in Science", and the first paragraph ends: "In a sentence our problem is: What do we mean by completeness in science, and to what degree is this completeness achieved or achievable?" Although this question is highly relevant to the first it is not the same question. That I have not merely misunderstood the author's intention of asking the same question in different words is I think shown by the inclusion of the fifth chapter on "The Gödel Incompleteness Theorem". This, it will be recalled, is concerned with formally undecidable sentences in formalized systems. Until "science", as distinct from (possibly) parts of physics, has been completely formalized—a consummation even the outlines of which are as yet hardly conceivable—the Gödel theorem cannot strictly apply. Schlegel is of course aware of this, but claims its relevance on the grounds that a "complete" enumeration of the sentences of a "descriptive science" would include (page 80) undecidable sentences. But is such a "complete" inventory relevant to the function of science? And even if it were, ought not the author to make it quite clear that the "incompleteness" inherent in formal undecidability is hardly if at all related to the incompleteness expressed in his own words: "the explicit structure of science must be regarded as a statement of a few abstracted aspects of the totality of nature; aspects that have universality and are of importance to us, but do not constitute the entirety of experience. In a word science is a very, very partial account"?

There are thus two distinct questions—completeness in science and completeness of the scientific account of—

account of what? Here again, although providing many illuminating insights towards answering the question—the tenth chapter "The Observer in Quantum Physics", and the section of the second chapter in which he applies Margenau's epistemological schema of "constructs", are at the very heart of the problem—Schlegel never makes explicit whether he is talking about "nature" as a convenient symbol for the totality of human experience ("including ourselves", page v), or what Eddington called "Nature", designated by Schlegel as "her" (page v). But, leaving aside the question of our "knowledge" of sensible objects, once we pass beyond this, "interaction" becomes virtually a postulate: knowledge of, say, an electron is restricted to the "interaction" between some arbitrarily applied "stimulus" and some component of nature—there is no need to complicate the issue by introducing an "observer". To the unsensed "continuant" (Whitehead's "historic route of occasions") it is convenient to give the name "electron". Our knowledge of it is thus determined by what we compel it to do: of electrons "in a state of nature" we have and can have no knowledge, any more than of the "smell" of nitric oxide. Although Dingle may be accredited with administering the necessary shock, it is, I believe, the "fishing net" analogy suggested by Eddington and the more abstract approach of von Weizsäcker and Cassirer that put the matter in a manner avoiding solipsism or extreme idealism. Yet despite Schlegel's admission that nuclear ejects are probably "made" by "interaction" with artificially accelerated particles (page 227), the general reader is given no hint of the fundamental importance of "interaction" until a fairly late stage in the study of "quantization"; and its general relevance to the problem of "complete description of nature" is nowhere worked out.

For somewhat similar reasons I am suspicious of the relevance of the otherwise fascinating application of the theory of transfinite cardinals and infinite sets to the problem of the "number of objects in the universe". Schlegel's distinction between the "infinite" as an "operator" ("make the finite cardinal as large as you please"), and the transfinite aleph zero as an actual cardinal, having defined (or postulated) properties based on one to one correspondence, with counting explicitly excluded, is well taken. But the application of transfinite correspondence to attaining "a measure of understanding and information with respect to infinite [countable] quantities of any kind: atoms, stars, parsecs, or years" seems to me open to the objection that the transfinite are arbitrarily constructed objects to enable mathematicians to deal with such arbitrary objects as the "points" in the continuum. As long as you follow the rules of correspondence you can deduce relationships otherwise inaccessible; but the essence of "quantization" in nature is the recognition of the non-existence of infinitely divisible objects. The spatio-temporal continuum has held out so far, but has been under fire from many quarters.

One further aspect of these questions calls for critical comment—the language of science. Dedicated scientists will not be much perturbed by the question of "completeness of description"; but ordinary folk, including ordinary school children, are showing signs of disquiet. The time may come when ordinary tax-payers begin to question the increasing annual sacrifice to the sacred cow. If the risk of a retreat from science into anti-science is to be avoided, scientists must heed Professor Denys Wilkinson's warning and refrain from expressing the relations of abstract systems in terms trailing clouds of confusion from long association with the familiar concrete. I have already referred to the "existence" of mesons "in" the nucleus. But "expanding universe", "curved space", "infinite distance" (which Carnap long ago replaced by "straight line having no greatest co-ordinate"), even "position and velocity at an instant" are likewise replete with possibilities of confusion and internal

contradiction, although they refer to concepts that can be given a precise connotation within a theory. Schlegel seems to accept this in principle (page 151) but fails to fasten the reader's attention to its importance.

This review has been almost entirely critical: I hope Schlegel would regard it as a response to his para-Gödelian sentence, "I would have known that I had failed if I had come to a final answer". My comments are intended to supply a small contribution towards the strengthening of what appear to me to be a few weaknesses in the philosophical foundations in a book that has made me think and think hard. I hope that it will engage the thoughts of a wide circle of readers. It is admirably produced: only two trivial typographical slips caught my eye.

WILLIAM P. D. WIGHTMAN

## ODDMENTS OF OPTIMIZATION

### Topics in Optimization

Edited by George Leitmann. (A Series of Monographs and Textbooks on Mathematics in Science and Engineering, Vol. 31.) Pp. xv+469. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) \$18.00.

THIS book is a collection of ten papers dealing with various aspects of optimal control theory. The stated purpose of the collection is to record in permanent format worthwhile contributions which are too long for inclusion in technical journals. Some material in the longest contribution, "On the Geometry of Optimal Processes", by Blaquiére and Leitman, however, has already appeared in book form, while several other contributions are short enough to appear in journals. Indeed, as in other similar collections, it is unlikely that more than one or two of the contributions will be of particular interest to a reader. This book is, however, distinguished by a most interesting and important contribution by Halkin, "Mathematical Foundations of System Optimisation". In this chapter Halkin outlines a geometric proof of the maximum principle, which he developed several years ago, and whose exposition he has refined in successive papers. By means of a new theorem he is now able to develop the proof "without introducing measurable control functions which are mathematical artifacts, completely out of place in control theory". This simplification makes the proof understandable by a relatively wide audience, and will be much appreciated. This chapter is, without doubt, the most important in the book. Another useful and interesting contribution is the chapter on singular extremals by Kelley, Kopp and Moyer. The maximum principle does not provide an adequate test for optimality on singular subarcs; this results in the failure of normal gradient methods of optimization. Singular extremals occur in problems of practical interest, and so the development of suitable numerical procedures is an important task. This is not done in this contribution, but a useful derivation of the conditions of minimality of singular arcs over short intervals of time is presented. The chapter by Blaquiére and Leitman presents (in 107 pages) a geometric approach to optimal processes which is at first sight very appealing, but which leads to considerable complexity. Halkin's proof of the maximum principle is undoubtedly preferable. The remaining contributions are either actually or potentially short enough for publication in journals, and deal with: bang-bang principle for non-linear systems; the relationship between classical calculus of variations, functional analysis and optimal control theory; inequalities and discontinuities in variational problems; determination of optimal control of a boosting vehicle; optimal problems in the theory of magnetohydrodynamics; numerical methods for the determination of minimum time control.

D. Q. MAYNE

## INFRARED SPECTRA

### Interpreted Infrared Spectra

Vol. 3. Including a Cumulative Index. By Herman A. Szymanski. Pp. ix+275. (New York: Plenum Press Data Division, 1967.) \$12.50.

THE third volume of Szymanski's *Interpreted Infrared Spectra* is devoted to phenols, ethers and peroxides. For each class, spectra with vibrational assignments are presented for typical compounds. This is followed by a short discussion of correlations and a table of appropriate group frequencies. Then the spectra of some fifty or sixty compounds in each class are reproduced, attention being drawn to the various group frequencies and any special points in each case. The aim is to provide instruction in spectral interpretation by showing how the significant bands may be identified and recognized in the spectra of related compounds, even where interfering bands may be encountered in some instances.

A short literature survey on phenols covers hydrogen bonding, and the effects of *ortho*- and *para*- substituents. Ethers are dealt with at some length in two separate sections, non-cyclic and cyclic ethers. Group frequencies for peroxides and hydroperoxides are discussed in relation to ethers and alcohols respectively. Some tentative —O—O— stretching frequencies are assigned but this band has only a limited diagnostic value.

The reasons underlying the choice of spectra are not always clear. Thus for the first member of the ethers, dimethyl ether assignments reported in 1945 and 1957 are given but more recent work is not included. Consequently, the book has limited value to those interested in detailed assignments. It will be of most value to those who wish to make use of group frequencies and know the class of compound they are working with. Interestingly enough, the author confesses to the view that where it is a question of identifying an unknown from an infrared spectrum he is convinced the only method is an exact matching of each band using a computer sort.

A cumulative index covering not only phenols, ethers and peroxides, but also alcohols and alkynes, is provided. The book is splendidly produced, tables well set out, and spectra clearly reproduced.

D. J. MILLEN

## LINEAR ALGEBRA

### Linear Algebra

By Walter Nef. Translated from the German by J. C. Ault. (European Mathematics Series.) Pp. x+305. London: McGraw-Hill Publishing Company, Ltd., (1967.) 80s.

THERE are many books on linear algebra. What is different about this one? The special feature is the blending of pure and applied aspects of the subject. This book is not a practical primer on the matrix calculus, such as might be useful to those engaged in computation; and it is not devoted exclusively to the theory of vector spaces and their linear mappings. Instead it lays the foundation for the theory of linear algebra and then proceeds to an introduction to linear programming and the theory of games. As a result, the book will be of special value to those students who will be concerned with applications but who wish to understand the fundamental theory at the back of what would otherwise be little more than a set of rules and recipes.

The book opens with a short chapter on sets and mappings and then proceeds to the initial treatment of vector spaces, including the theory of cosets (linear manifolds) and quotient spaces. The next chapter is concerned with bases of a vector space, especially a space of finite dimension. It includes a discussion of the exchange method of numerical calculation. The following chapter, on determinants, starts with a treatment of permutations

and then defines the determinant, of order  $n$ , as a scalar function of  $n$  vectors (each with  $n$  components) which satisfies certain conditions. The reader will notice that, so far, matrices have not been introduced. But the next chapter, which introduces linear mappings of a vector space, presents the matrix as a representation of such a mapping. Numerical inversion of matrices (of low order) is discussed. Linear functionals are introduced in the following chapter and are used in a discussion of the important concept of duality in a finite dimensional vector space. Then there is a chapter on systems of linear equations and systems of linear inequalities, the latter occurring in the subject of linear programming, which is treated in the following chapter. The treatment is not, of course, exhaustive but it includes a discussion of free variables and the duality law. There is, in the next chapter, an account of Chebyshev approximations and this is of particular value because the topic is usually omitted in books on linear algebra. A short chapter on game theory, which proceeds as far as the evaluation of games by the simplex method, is followed by chapters on quadratic and Hermitian forms and on Euclidean and unitary vector spaces. In this second chapter Hilbert space is introduced and thus contact is made with the subject of linear analysis. The book closes with two chapters covering eigenvalues, eigenvectors and canonical forms.

It is likely that some students will not find the book an easy one. The exposition is actually very clear, but it presupposes an introduction to abstract algebra at the matriculation and first year level, which many students may not have had. This highlights again the need for overall revision of syllabuses at the school level. On the other hand, it must be admitted that not all those interested in the use of mathematics will be capable of much abstract thought. For these, as far as linear algebra is concerned, the present book is not the text to follow.

L. S. GODDARD

## MACHINES COME TO LIBRARIES

### Library Planning for Automation

Edited by Allen Kent. (Based on the proceedings of a conference held at the University of Pittsburgh, June 2-3, 1964.) Pp. ix+195. (Washington, D.C.: Spartan Books, Inc.; London: Macmillan and Co., Ltd., 1965.) 52s. net.

THIS volume begins with a visionary description by Dr Stafford L. Warren of a proposed national science library system for the United States, consisting of a network of terminals linked electronically to a central store, by means of which on-line access could be had to the whole text (not simply to the titles) of scientific periodical literature. This would be an extension of the system developed by the National Library of Medicine, which is still the most sophisticated development of automated bibliography. There follows a chapter by Dr Andrew D. Osborn of the University of Pittsburgh, who introduces the professional librarian's realism and practical expertise.

The book illustrates the lack of *rapprochement* which can result from the failure to distinguish between the development of a purely scientific information system primarily relying on periodical literature, and the possible role of automation in a general library. Dr Warren writes with the first of these in mind, while Dr Osborn criticizes him from the second standpoint and issues some salutary caveats. A well indexed book is as good a form of random access as has yet been devised. It is important that lack of sympathy for the information officer's approach should not blind librarians to all that automation can achieve in a general library (up-dating of catalogues, output printing, control of accessions and borrowing). The overall plans produced by Dr Warren are stimulating and ought to shape much thinking in this country. Dr Warren is a

special assistant to the President of the United States. The expenditure he advocates is on a very large scale. When, in this country, shall we see advocacy on this level of such far-reaching and imaginative schemes?

ROBERT SHACKLETON

## FURTHER DEVELOPMENT

### The Biochemistry of Animal Development

Edited by Rudolf Weber. Vol. 2: Biochemical Control Mechanisms and Adaptations in Development. Pp. xiv+481. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 168s.

THE biochemistry of development is not a subject of which all aspects can be discussed fully in two volumes of review articles, especially if development is used in its widest sense to include regeneration, metamorphosis, growth control and so on. For this reason the editor has selected eighteen aspects of the subject for detailed review (ten in the first volume and eight in the second), and these books are to be regarded as collections of essays, between which overlap has been largely avoided. The second volume deals mainly with the control of developmental processes and contains articles on primary embryonic induction (by Tiedemann), metabolic regulation of growth and differentiation (by Papaconstantinou), nucleo-cytoplasmic interactions (by Chen), metamorphosis (by Weber), and regeneration (by Flickinger); the last three chapters, by Williams, Villet and Fisher, concern respectively yolk utilization, the mammalian placenta, and nitrogen metabolism in embryos. The main emphasis has been on vertebrate embryos and is justified by the distribution of current biochemical knowledge of embryos and differentiating cells.

Each article in the book constitutes a detailed and comprehensive review of the topic concerned, and this is where the main merit of the work lies. At a time when embryologists are required to have some familiarity with work classified as genetics, cytology, molecular and cell biology, there is a real danger that old, or even recent, as opposed to current, literature will be overlooked. Lengthy review articles of the kind included in this volume constitute most valuable sources of information and references, and speculation which is not extensive is clearly distinguished from facts. As might be expected, however, this treatise does not constitute light reading, and serves more as a source of results and facts than of ideas. Thus several contributors have chosen, as in the first volume, to divide the work they discuss into categories corresponding to the taxonomic groups of animals concerned. This kind of treatment tends to result in uncohesive lists of achievements, but is of value in subjects, like the biochemistry of development, where a new finding may well turn out to link up a number of otherwise isolated pieces of information the significance of which was previously little, if at all, understood.

This volume is devoted to the control of developmental processes. At our present level of knowledge this usually involves showing a relationship between a developmental event and an altered biochemical pattern or pathway. As several contributors have pointed out, this does not show whether the relationship is causal or consequential. Until questions of this kind can be answered, ideally by creating known biochemical alterations in living cells, progress requires the accumulation of as much information as possible about the biochemical events associated with a given developmental process. Much of this information has been conveniently collected in these two volumes.

The limitations of these books are largely unavoidable and not serious. First, there are necessarily some aspects of the biochemistry of development, which are not fully covered, but these are surprisingly few and of these most are at least mentioned by one or other contributor.

Second, most articles appear to have been completed in 1965, about two years before publication. This is not a disadvantage as long as the contributions are recognized as digests of the relevant literature up to 1964/65. The price of the book is high, but it is well produced and the illustrations appear good.

The first and second volumes of this treatise constitute a most useful contribution to the study of development. They will be valuable as reference books for several years to come, especially for graduate students and research workers. It is perhaps unfortunate that two other books composed of collections of essays on the biochemistry of development should also have been published very recently: *Current Topics in Developmental Biology*, Vol. 1, and *Comprehensive Biochemistry*, Vol. 28, edited by Florkin and Stotz. The latter together include review articles by no less than five of the same authors as have contributed to *The Biochemistry of Animal Development*. In at least one case the two contributions of the same author are not easily distinguishable.

J. B. GURDON

## EXCITABLE CELLS

### The Molecular Properties and Evolution of Excitable Cells

Vol. 35. By C. J. Duncan. (International Series of Monographs in Pure and Applied Biology: Division of Zoology.) Pp. xi + 233. (Oxford, London and New York: Pergamon Press, Ltd., 1967.) 70s. net.

THE object of this monograph is to present a concrete hypothesis linking the evolution and the molecular properties of excitable cells. This is a formidable task, made all the more so by the multi-disciplinary approach entailed in any attempt to formulate a comprehensive theory. The author takes as his starting point the findings in two neurophysiological monographs published in 1964 on axonal and synaptic transmission by the two distinguished authorities, namely A. L. Hodgkin and Sir Jack Eccles. In the presentation of his theory concerning the phenomena underlying these findings, he adduces supporting evidence which is largely that available in the relevant reviews in histochemistry, electronmicroscopy, biochemistry, molecular biology, pharmacology and physiology.

Obviously, such a theory can only represent the views of one man, Dr. Duncan, and attempts to collate findings in many fields call for critical selection and the discarding of data from the plethora of those available. Selection of data, together with the interpretations placed thereon, carries the personal imprint of Dr. Duncan and, of course, can hardly be expected to receive universal approbation but, nevertheless, this brave attempt can hardly fail to stimulate its readers.

Dr Duncan points out that the primitive form, amoeba, reacts to mechanical deformation of its surface membrane by a locomotor action combining receptor and effector in one cell. Development interpolates a conducting cell or neurone which provides a specialized mechanism for excitation by stimuli, propagation of the excitation and its delivery to an effector cell. This development of rapid transmission of excitation by the axon requires little modification of inherent membrane properties.

In this volume Dr Duncan discusses the mechanoreceptors and the evidence for an enzyme transducer mechanism in sensory cells and attempts to relate ATPases with cation-permeability. He turns then to the mechanisms by which chemical, thermal and light stimuli are converted into nerve impulses. Dr Duncan shows that transduction of these four forms of stimuli could arise from a common underlying mechanism, a further example of supreme exploitation by Nature on the lines of the utmost economy. He goes on to consider cholinergic synapses and the relation of acetylcholine

and cholinesterases to substances which modify synaptic function. The roles of adrenaline, noradrenaline,  $\gamma$ -aminobutyric acid (GABA) and of inhibitory synapses are considered and then sodium permeability and the release of synaptic chemical transmitters are examined. He touches on RNA and Nissl substance and on the fascinating hypothesis of the incorporation of a memory trace within the RNA molecule.

In the final chapter, Dr Duncan summarizes the main points of his theory and provides a master diagram to illustrate the main components and the points at which it is vulnerable to chemical agents. He relies strongly on pharmacological findings but some may feel that his speculations based thereon ask, in some instances, more from the evidence than is justified.

While the book would be unsuitable for medical, dental and ophthalmic optical students, it could prove of special value to senior B.Sc. students and graduates in the biological sciences because of its trans-disciplinary approach and wealth of information together with references to review sources which might not otherwise come to the attention of its readers.

It should be read, however, as a scholarly attempt to correlate knowledge from many different sources and to provide intellectual stimulation to critical assessment of the evidence and of the author's speculations. Such books are invaluable as catalysts of new ideas and new research and should be found a place in every biological library.

J. P. QUILLIAM

## YEASTS ALIVE

### The Life of Yeasts

Their Nature, Activity, Ecology, and Relation to Mankind. By H. J. Phaff, M. W. Miller and E. M. Mrak. (Harvard Books in Biology, No. 5.) Pp. ix + 186. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1966.) 44s. net.

THIS small volume makes no pretence to being comprehensive. Thus it is practically devoid of chemical formulae and makes little more than passing reference to well-known uses of yeasts on the large-scale such as in baking, brewing and wine-making. This latter remark is, however, in no way an adverse comment. It is rather intended to show how welcome is this simple but wide-ranging account of a field which for various reasons has hitherto mostly been described only in a few specialized texts or in many respects only piecemeal in original publications.

For instance, "yeast life" here basically embraces yeast morphology and life cycles. Topics such as yeast cytology, genetics, nutrition and ecology comprise ancillary fields while yeast spoilage and industrial uses of yeasts are treated more in an illustrative than in a fully descriptive way. The result is an essay which is not only interesting but well balanced and scholarly. Most botanists and microbiologists will appreciate this book as a more coherent account within its limitations of space than has hitherto been available. The individual specialist in, for example, yeast genetics or biochemical transformations will of course be aware of important developments which the authors have not included but will be agreeably surprised by the succinct way in which so much has been co-ordinated. Most readers including specialists will be surprised to learn or be reminded how recent are many of the findings in this field. It is easy to forget that the very concept of yeasts as distinct from other unicellular organisms is only about a century old, that the early faltering attempts at classification go back only about seventy years, that the first really systematic scheme of Stelling-Decker dates from 1931 and that even the present taxonomic schemes of Lodder-Kreger van Rij (1952) and Kudriavtzev (1954) together with technical methods (for

example, of Wickerham in 1951) remain subjects of debate. Likewise it will surprise many to have it recalled that the recognition of the alternation of generations in yeasts goes back only to 1935, that the concept of "sexual" mating types followed little more than twenty years ago and that the comparatively little that is known of yeast genetics is even more recent.

With its wealth of newly co-ordinated information the few quite unimportant errors can be disregarded. They are more than compensated by a number of appendices including a useful listing of genera and diagnoses. It is slightly regrettable that no original papers are cited though a list of probably all the major monographs of the field will to a large extent meet this need indirectly.

A. H. COOK

## LICHENS FOR STUDENTS

### The Biology of Lichens

(Contemporary Biology.) By Mason E. Hale, Jun. Pp. viii + 176. (London: Edward Arnold (Publishers), Ltd., 1967.) 42s. net boards; 21s. net paper.

THIS is a good book. It is an eminently successful account of lichens for the student. Although it does not aim to be an encyclopaedic work of scholarship, its coverage of the literature is remarkably good, and the clarity with which it is written is outstanding. Its scope is wide: it deals with the fundamental aspects of the morphology, reproduction, ecology and classification of lichens, and lays particular emphasis on the subjects of symbiosis, physiology and chemical taxonomy.

The most valuable quality of this book is the excellent way it deals with those aspects of the biology of lichens which are almost always misunderstood by students. The wealth of fascinating problems concerning reproduction of lichens is presented very clearly. In discussing concepts of symbiosis, Dr Hale gives very lucid explanations of what various authors have had in mind, but stresses our continuing ignorance of the nature of the lichen symbiosis. A section on the physiological relationships of the symbionts begins with the excellent statement: "Dialectic arguments about symbiosis are no substitute for experimental proof". At first glance, the chapter on the chemistry of lichens may seem to require more knowledge of organic chemistry than should be expected of a biology student. It is written, however, with superb clarity, and is an essential precursor to the succeeding chapter on chemical taxonomy, the best in the whole book.

As in any book, there are some small errors. I am embarrassed to be credited on page 61 with a comparison of rates of  $^{14}\text{CO}_2$  fixation between *Trebouxia* and *Chlorella*: this work was actually carried out by Cecil Fox. Drew's studies of *Peltigera polydactyla* mentioned on page 59 showed that glucose is converted to mannitol in the algal layer, not the medulla, during photosynthesis. Some of the plates are poor, and 1D, 1E and 6B look more like objects from outer space than algal cells and soredia. In the next edition, the printers really must try to make the fifteen labels on plate twelve more legible.

I found the chapter on ecology the least stimulating. I am most sorry that Ried's (1963) work on zonation of lichens was omitted, because I believe this to be the best and most thorough piece of physiological ecology carried out on lichens, and I feel it deserves a whole section in a book of this kind. In dealing with atmospheric pollution, it is a pity to find no mention of Gilbert's work on the Newcastle area, because this provides better direct evidence than most other ecological studies of the effects of sulphur dioxide on lichen distribution.

But despite such criticisms, which are the sort that one specialist can always make about another, this book is to be highly recommended.

D. C. SMITH

## USING THE LIGHT

### Primary Productivity in Aquatic Environments

Edited by Charles R. Goldman. (Proceedings of an I.B.P. PF Symposium, Pallanza, Italy, April 26-May 1, 1965.) Pp. 464. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1966.) \$7; 56s. net.

THIS volume is neither a recipe-book methodology nor a simple collection of research papers. Most of the contributions have a strong emphasis on the methods employed in production research and their potential sources of error, or on their underlying philosophy. Presumably the intention is to give examples of how freshwater productivity data can be obtained so that participants in the International Biological Programme can follow, modify or develop these examples.

Three examples from the twenty-seven contributions indicate the sort of topics and their treatment. Jorgensen and Steemann-Nielsen discuss the ways in which planktonic algae adapt themselves to factors such as temperature and light intensity, primarily by varying the concentrations of photosynthetic pigments and various enzymes. This is obviously important to anyone wishing to extrapolate from experimental data to the field situation.

Fogg and Watt discuss the release of glycolic acid as an extracellular product of photosynthesis by phytoplankton. The amounts released can be quite significant, more so in oligotrophic than eutrophic waters, and especially in surface waters at high light intensities. This is a potential source of error in the use of the radiocarbon method for estimating photosynthesis.

Margalef contributes a stimulating paper on the relationship between primary production and community structure in phytoplankton communities. This emphasizes the importance of (and therefore the need to measure) community structure either as some index of species composition, or as a simple pigment ratio.

Other important topics discussed include mechanisms of photosynthesis, the factors limiting primary production in natural phytoplankton populations, the importance of planktonic bacteria, production by higher plants in aquatic environments, the value of standing crop data in estimating primary production and the comparison of seasonal and spatial variation in phytoplankton populations and production rates in a temperate and a tropical lake.

Each paper has an abstract and a reference list and the whole volume is well edited and produced. The instigation and speedy publication of well-designed conferences will clearly be an important function of IBP and it has got off to a good start.

P. J. NEWBOULD

## POTTED MAMMALS

### Recent Mammals of the World

A Synopsis of Families. Edited by Sydney Anderson and J. Knox Jones, jun. Pp. viii + 453. (New York: The Ronald Press Company, 1967.) \$12.50.

THIS book is the culmination of a series of check lists or bench books compiled for their own use by a succession of graduate students and staff members of the University of Kansas. It began as long ago as 1953 when the contributors prepared an outline of each order and family of living mammals; this proved so useful that it was improved and extended in 1959, and then further revised and expanded with the assistance of mammalogists in other institutions to form the present volume. As the editors say, the final result reflects a commendable degree of teamwork on the part of all contributors in writing to agreed standards of objectivity and conciseness.

The introductory chapter summarizes the characters of mammals, the zoogeographical regions—with a table showing the distribution and diversity of recent mammals—and explains the methods of presentation of the information in the main body of the work. The second chapter gives a synopsis of the fossil history of the families of recent mammals, and packs much information into a small space. Simpson's classification is followed for the greater part, but the cetaceans are treated as two orders, and the pinipedes are ordinarily separated from the fissipede carnivores. The writing throughout is telegraphic in style for the sake of brevity.

The synopsis of each family is arranged under a set of standard headings: diagnosis, general characters, habits, habitat, recent distribution, a list of recent genera with the number of species, geological range, major fossil groups, and remarks. The orders are treated similarly *mutatis mutandis*, and a distribution map is provided for nearly every family. The information given is well documented, and there is an extensive bibliography and a full index. The similarity of organization throughout the volume makes it easy to find and compare information in the accounts of the different families. In a compilation from so many sources, by so many contributors, there are bound to be some mistakes, but a set of test questions failed to reveal any errors.

The book is intended to provide a ready source of information about the living mammals not only for mammalogists but also for other people interested in mammals who work in other disciplines on which mammals impinge such as botany, entomology, ecology or geography. In addition to giving an enormous amount of information in small compass, it is an excellent source book for more detailed studies. It is one of the most useful books about mammals that has appeared since Flower and Lydekker's *Introduction to the Study of Mammals* was published in 1891, and all those to whom it is addressed will find it indispensable and will be accordingly grateful to the team of authors for their enterprise and skill.

L. HARRISON MATTHEWS

## SMALL WORLD

### An Illustrated Catalogue of the Rothschild Collection of Fleas (Siphonaptera) in the British Museum (Natural History)

By G. H. E. Hopkins and Miriam Rothschild. Vol. 4: Hystriehopsyllidae (Ctenophthalminae, Dinopsyllinae, Doratopsyllinae, and Listropsyllinae). Pp. viii + 549 + 12 plates. (London: British Museum (Natural History), 1966.) n.p.

THE publication of a volume of the *Illustrated Catalogue of the Rothschild Collection of Fleas* is a real event for anyone interested in siphonapterology. This so-called catalogue is actually nothing less than a handbook for the identification of all the known species and sub-species of fleas. It not only catalogues the numerous specimens present in the Rothschild and British Museum (Natural History) collections of fleas but also gives keys for identification and short descriptions of all taxa.

The work is of great interest because of its contents, and the way in which the great task of compiling it has been carried out deserves much admiration. The keys and descriptions are lucid; the latter are not long-winded; they have been reduced to essential characters. The numerous excellent figures (926 in this volume) of structures of taxonomic importance are supplemented by twelve plates with photographs of whole fleas or of particular taxonomic features. It is impossible to appreciate here all the excellent details of this work which must rank among the best publications in the field of systematic entomology.

The present volume contains the greater part of the large family Hystriehopsyllidae, including the large genus

*Ctenophthalmus kolenati*. The classification of this genus follows modern ideas, especially those of Smit, and the genus is subdivided into thirteen sub-genera. A "list of taxa not in volumes I to III inclusive", in the appendix, gives references to the taxa belonging to families treated in previous volumes of the catalogue and which have been described since.

The two authors and the trustees of the British Museum (Natural History) are to be congratulated for this admirable book and to be thanked for the painstaking work involved in its completion. I trust that it will be widely used and distributed. It should not be missing from any entomological library, because it should serve, apart from its special subject matter, as a model for papers on taxonomy.

E. HAESELBARTH

## BACKWARDNESS IN READING

### The Disabled Reader

Education of the Dyslexic Child. Edited by John Money. Pp. xiii + 421. (Baltimore: The Johns Hopkins Press; London: Oxford University Press, 1966.) 68s. net.

THIS is a collection of articles—some new, others reprinted—concerned with various aspects of the problem of selective backwardness in reading and spelling. It is "inter-disciplinary" in the modern fashionable sense, with the authors drawn from child psychiatry, paediatrics, experimental psychology, linguistics and remedial education. (Oddly, there is only one neurologist, and he is half psychologist.) While predominantly American in tone, British workers are by no means unrepresented.

The book is divided into two main parts, the first concerned with reading and the analysis of reading backwardness, and the second with teaching methods and the organization of classes for the backward reader. Then come five clinical case reports and an account of some special disabilities in perception and orientation encountered in backward readers. There is a short concluding section, a glossary and a bibliography.

Although the nature and origin of severe backwardness in reading are still imperfectly understood, it now seems clear that at least two major varieties of the disability exist. The first appears in the context of overall language retardation which, in some cases at least, may have a genetical basis. The second appears along with more widespread defects in visual orientation and spatial judgment, and is not infrequently linked with early, minimal brain damage.

The nature of the disability, too, appears to differ somewhat in these two main groups, being largely a difficulty in linking visual with phonetic elements in the first, and of visual orientation and recognition in the second. It should not be impossible to devise remedial methods specifically adapted to these particular forms of disability.

As regards the remedial methods described in this book, there is no doubt that they are largely *ad hoc*, or at all events based on a distinctly insecure rationale. It would be an immense step forward if this book should lead psychologists, doctors and remedial teachers to design genuinely inter-disciplinary research on methods of remedial treatment and to test their efficacy by controlled experiment.

Dr John Money has done much in recent years to focus interest on backwardness in reading and to stress the need for more adequate scientific study of its causes and treatment. In spite of the scrappiness inseparable from compilations of this kind, his book should be warmly welcomed by all concerned with the very real problems of the dyslexic child and those who teach him.

O. L. ZANGWILL

## OBITUARIES

### Professor Gregory Goodwin Pincus

GREGORY PINCUS, who died on August 22, was born in Woodbine, New Jersey, on April 9, 1903. He received his B.S. from Cornell University in 1924 and both his M.S. and Sc.D. degrees from Harvard in 1927. After graduation he served as a Fellow of the National Research Council for three years. In 1931 he became assistant professor at Harvard in the department of general physiology of Professor W. J. Crozier, and in 1938 he went to Clark University as a visiting professor of experimental zoology, holding a Guggenheim Fellowship from 1939 to 1941.

In 1944 he and I established, at Clark University, the entirely independent Worcester Foundation for Experimental Biology, and we have served as its co-directors since its foundation. This institute has become a distinguished centre of biomedical research and postdoctoral training.

Pincus' work in the field of endocrinology has been very notable. He was responsible for new methods of steroid analysis. He and his collaborators conducted many studies of stress in relation to adrenal cortical functions; studies of the role of steroids in cancer of the breast and of the reproductive system; studies of steroid hormones in relation to cardiovascular disorders and also in relation to problems of human ageing. During the mid-1930's his work on mammalian reproduction produced the first parthenogenetic mammals—rabbits that had mothers but no fathers. He was a pioneer in producing multiple ovulation in animals and in transplanting animal ova from females producing the ova to females that carried and developed the embryos to term. Since 1950 his work on the control of fertility has had widespread repercussions with regard to the "population explosion". He was the principal investigator in the development of the first successful oral contraceptive and he and his group continued to investigate a number of steroid contraceptive agents.

Pincus was chairman or a member of many important national committees and of international conferences and congresses. He was a Fellow of the American Academy of Arts and Sciences and a member of the National Academy of Sciences. He was a member or honorary member of physiological and endocrinological societies throughout the world. He was the recipient of numerous prizes, including the Oliver Bird Prize for 1957, the Albert D. Lasker Award in Planned Parenthood, 1960, the Sixth Annual Julius A. Koch Award, 1962, the Modern Medicine Award for Distinguished Achievement, and the City of Hope National Medical Center Award, both in 1964, the Cameron Prize in Practical Therapeutics (University of Edinburgh) in 1966, the Barren Foundation Medal also in 1966, and the American Medical Association Scientific Achievement Award in 1967. He had also been made an honorary professor at the San Marcos University in Lima, Peru.

His books include *The Eggs of Mammals*, published in 1936, and *The Control of Fertility*, published in 1965. He was the author of many scientific papers and served on editorial boards of *Experimental Biology Monographs* and the *American Journal of Physiology*, and was editor or co-editor of books such as *Hormones and the Aging Process* and *Hormones and Atherosclerosis*. He was co-editor of five volumes entitled *The Hormones* and he was consulting editor to *Life Sciences*.

Dr D. Ewen Cameron, past president of both the American Psychiatric Association and the World Psychiatric Association, wrote, in the *New York Times*, concerning the contributions of Pincus in the field of fertility control: "few contributions to medical knowledge have done so much to bring to women everywhere a sense of worth and dignity".

HUDSON HOAGLAND

### Appointments

PROFESSOR B. KATZ, professor and head of the Department of Biophysics at University College, London, has been appointed a member of the Agricultural Research Council on the retirement of Professor T. A. Bennet-Clark.

### Announcements

DR L. H. TURNER of the Leptospirosis Reference Laboratory of the London School of Hygiene and Tropical Medicine, Keppel Street, London, WC1, is acting as convenor of a group of 40 people concerned with the taxonomy and nomenclature of the order Spirochaetales. One possibility is that the group may eventually become a taxonomic sub-committee under the aegis of the International Committee on the Nomenclature of Bacteria. Persons wishing to be associated with the project should write to Dr Turner.

NOMINATIONS are invited for the Beilby Medal and Prize which is awarded annually to a British scientist in recognition of his work in such fields as chemical engineering, fuel technology and metallurgy. Further information can be obtained from the Convenor of the Administrators, Sir George Beilby Memorial Fund, The Royal Institute of Chemistry, 30 Russell Square, London, WC1.

NOMINATIONS are invited for the award of the Meldola Medal which is made annually to the British chemist under the age of 30 who shows most promise in his or her published chemical work. Further information can be obtained from the President, The Royal Institute of Chemistry, 30 Russell Square, London, WC1.

THE opening meeting of the 61st session of the Society of Tropical Medicine and Hygiene will be held at Manson House, 26 Portland Place, London, W1, on October 19 at 7.30 p.m. Further information can be obtained from the Royal Society of Tropical Medicine and Hygiene at the above address.

### Meetings

PEAT and Organic Soils, September 25–27, Southport (Mr H. T. Davies, North of England Soils Discussion Group, Department of Soil Science, National Agricultural Advisory Service, Government Buildings, Lawnswood, Leeds).

GRANITES and Basement of North-Eastern Brazil and their Comparison with those of West Africa, October 1–14, Recife, Brazil (M. J. Lombard, Secrétaire Général de l'Association des Services Géologiques Africains, 12 rue de Bourgogne, Paris 7e).

ULTRASONICS, October 4–6, Vancouver (R. L. Guthrie, Boeing Scientific Research Laboratories, P.O. Box 3981, Seattle, Washington).

SINGLE-CELL Protein, October 9–11, Massachusetts Institute of Technology (Single-cell Protein Conference, Room 16–325, Massachusetts Institute of Technology, Cambridge, Massachusetts).

ANALYTICAL Chemistry in Nuclear Technology, October 10–12, Gatlingburg, Tennessee (C. K. Tipton, Oak Ridge National Laboratory, P.O. Box X, Oak Ridge, Tennessee).

PHYSICS of Selenium and Tellurium, October 12–13, Montreal (Selenium-Tellurium Development Association, Inc., 11 Broadway, New York, NY).

DENTAL Medicine, October 12–14, High Tatras Mountains, Czechoslovakia (Secretary of the Congress, Dr J. Ležovič, Bezručova 5, Bratislava, ČSSR).

APPLICATION of Automation in the Process Industries, October 16–17, Amsterdam (The Institution of Chemical Engineers, 16 Belgrave Square, London, SW1).

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Tuesday, September 19

SOCIETY OF CHEMICAL INDUSTRY, HEAVY ORGANIC CHEMICALS GROUP (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Dr A. R. Graham: "Resorcinol from M-Diisopropylbenzene".

## Wednesday, September 20

SOCIETY OF INSTRUMENT TECHNOLOGY (at the A.E.I. Cinema, 33 Grosvenor Place, London, S.W.1), at 5.30 p.m.—Inaugural Meeting followed by "Practical Data Logging—Possibilities, Pitfalls and Progress" (A 'Manufacturer and User' Forum).

OIL AND COLOUR CHEMISTS' ASSOCIATION, LONDON SECTION (in the New Engineering Block, University College, Gower Street, London, W.C.1), at 6.30 p.m.—Mr N. R. Wheeler: "Art Forms from Newer Materials".

## Wednesday, September 20—Friday, September 22

BRITISH CAST IRON RESEARCH ASSOCIATION (at the University of Technology, Loughborough)—Conference on "Electric Melting and Holding Furnaces in the Ironfounding Industry".

INSTITUTE OF PHYSICS and the PHYSICAL SOCIETY (at University College London, Gower Street, London, W.C.1)—Conference on "Stress Analysis in Bio-Engineering".

SOCIETY OF INSTRUMENT TECHNOLOGY (at the University, St. Andrews, Fife)—Conference—"On-Line Measurement and Inspection—Their Impact on Quality".

## Thursday, September 21

INSTITUTION OF MINING AND METALLURGY (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr A. J. Ellis, Dr J. S. Tooms, Prof J. S. Webb and Mrs J. V. Bicknell: "Application of Solution Experiments in Geochemical Prospecting"; Mr T. R. Groundwater: "Role of Discounted Cash Flow Methods in the Appraisal of Capital Projects".

INSTITUTION OF MECHANICAL ENGINEERS, MANUFACTURE AND MANAGEMENT GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion Meeting on "Getting the Best Out of People".

## Thursday, September 21—Friday, September 22

CHALLENGER SOCIETY and REPRESENTATIVES from the MARINE LABORATORIES (Natural Environment Research Council Scheme) (at the National Institute of Oceanography, Wormley, near Godalming, Surrey), at 10 a.m. daily—Papers on Physical Oceanography and Biological Oceanography.

INSTITUTE OF PHYSICS and the PHYSICAL SOCIETY (at the Central Electricity Research Laboratories, Leatherhead, Surrey)—Conference on "Electroless Breakdown of Gases, including Laser Produced Breakdown".

ROYAL ENTOMOLOGICAL SOCIETY OF LONDON (at the Imperial College of Science and Technology, London, S.W.7)—Symposium on "Insect Abundance".

SOCIETY FOR WATER TREATMENT AND EXAMINATION (in the Physics Lecture Theatre, The University, Newcastle-upon-Tyne)—Autumn Meeting. Mr R. Briggs and Mr K. Melbourne: "Recent Advances in Water Quality Monitoring"; Mr D. G. Hager and Mr R. D. Fulker: "Adsorption and Filtration with Granulated Activated Carbon"; Mr K. D. B. Johnson: "Desalination in Britain"; Mr E. E. Finney and Mr N. J. Nicolson: "The Evaluation of Analytical Methods".

## Friday, September 22

BRITISH MYCOLOGICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 10.45 a.m.—Symposium on "Some Aspects of the Fungal Hypha".

## Friday, September 22—Saturday, September 23

SOCIETY FOR ANALYTICAL CHEMISTRY, MICROCHEMICAL METHODS GROUP and SPECIAL TECHNIQUES GROUP (at the University of East Anglia, Norwich), at 9.45 a.m. daily—Meeting on "Molecular Spectroscopy in Microanalysis".

## Monday, September 25—Wednesday, September 27

INSTITUTE OF CANCER RESEARCH: ROYAL CANCER HOSPITAL (at Imperial College of Science and Technology, London, S.W.7)—International Nuclear Medicine Symposium on "Radioactive Isotopes in the Localization of Tumours".

## Monday, September 25—Friday, September 29

INSTITUTION OF MECHANICAL ENGINEERS (at Church House, Westminster, London, S.W.1)—Conference on "Lubrication and Wear—Fundamentals and Application to Design".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (with high academic qualifications and preferably special experience in certain aspects of industrial metallurgy) in METALLURGY—The Principal, Lanchester College of Technology, Priory Street, Coventry (September 19).

SENIOR LECTURER (with substantial research and teaching experience and eligible to apply for recognition as a teacher of London University) to take charge of COMPARATIVE PHYSIOLOGY—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3 (September 20).

SENIOR SCIENTIFIC ASSISTANT (with a certificate in microbiology at H.N.C. level or its equivalent, or with equivalent experience) in the BACTERIOLOGY DEPARTMENT, for duties which include general laboratory organization and training and supervision of scientific assistants—The Secretary, Hannah Dairy Research Institute, Ayr, Scotland (September 20).

PRINCIPAL LECTURER (honours graduate in pharmacy with a higher degree or equivalent research experience) in PHARMACEUTICS—The Secretary, Robert Gordon's Institute of Technology, Aberdeen, Scotland (September 25).

RESEARCH FELLOW or ASSISTANT (graduate in mathematics, physics or electrical engineering, and preferably experience in the communications field or in programming a digital computer) in ENGINEERING for studies in the synthesis of lumped linear electrical networks—The Registrar, The University, Leicester (September 25).

RESEARCH FELLOW (with research experience of electronics and high vacuum techniques) in the DEPARTMENT OF PHYSICS to work on a hydrogen beam maser project under the direction of Dr D. C. Lainé—The Registrar, The University, Keele, Staffordshire (September 26).

ASSISTANT EXPERIMENTAL OFFICER (with a degree, H.N.C., or equivalent qualification) for electron microscopy of various biological materials—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. 1052/102 (September 29).

LECTURER or ASSISTANT LECTURER (with a science degree with a major in physics) in PHYSICS at the University of Botswana, Lesotho and Swaziland—The Inter-University Council, 33 Bedford Place, London, W.C.1 (September 29).

EXPERIMENTAL OFFICER (with experience of instrument design or construction involving electronics or optics, and preferably some experience in spectroscopy) in the DEPARTMENT OF CHEMISTRY—The Registrar, The University of Manchester, Manchester, 13, quoting Ref. 144/67 (September 30).

PROFESSOR OF AGRICULTURAL SYSTEMS AND ORGANIZATION in the DEPARTMENT OF AGRICULTURE—The Registrar (Room 39, O.R.B.), The University, Reading (September 30).

PROFESSOR OF CROP PRODUCTION in the DEPARTMENT OF AGRICULTURE—The Registrar (Room 39, O.R.B.), The University, Reading (September 30).

RESEARCH FELLOW (with or expecting to receive a Ph.D. and preferably previous research experience relevant to the project) in the SCHOOL OF PHYSICS, for work on the growth, structure and properties of single crystals of oxides, nitrides and carbides with the aim of developing new composite ceramic materials—The Registrar, University of Warwick, Coventry, Warwickshire (September 30).

COMPUTER MANAGER—The Secretary, University of Stirling, Stirling, Scotland (October 2).

TEACHING FELLOW (with an honours degree in science or equivalent qualifications) in the SCHOOL OF CHEMISTRY, University of New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 2).

HEAD (preferably with interest in the development of research projects) of the DEPARTMENT OF PHARMACY—The Principal, College of Technology, Belfast, Northern Ireland (October 7).

LECTURER in BIOCHEMISTRY—The Secretary, The University, Dundee, Scotland (October 7).

DIRECTOR (with postgraduate training in computer science and numerical analysis plus experience in their application) of the UNIVERSITY COMPUTER CENTRE, University of Ibadan, Nigeria—The Inter-University Council, 33 Bedford Place, London, W.C.1 (October 9).

LECTURERS or ASSISTANT LECTURERS in the DEPARTMENT OF SOCIOLOGY, University of Singapore—The Inter-University Council, 33 Bedford Place, London, W.C.1 (October 10).

SENIOR LECTURER or LECTURER (preferably with an interest in taxonomy and plant ecology) in the DEPARTMENT OF BOTANY and PLANT PATHOLOGY, University of the West Indies, Trinidad—The Inter-University Council, 33 Bedford Place, London, W.C.1 (October 10).

LECTURER in the DEPARTMENT OF FUEL TECHNOLOGY and CHEMICAL ENGINEERING—The Registrar, The University, Sheffield (October 16).

DEMONSTRATOR/SENIOR DEMONSTRATOR in the DEPARTMENT OF INORGANIC CHEMISTRY—The Registrar, The University, Newcastle upon Tyne, 2 (October 20).

LECTURER/SENIOR LECTURER in BIOCHEMISTRY at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 20).

DIRECTOR of the COMPUTER LABORATORY—The Registrar, The University, Liverpool, quoting Ref. RV/170/N (October 31).

FORBES CHAIR OF ORGANIC CHEMISTRY—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (October 31).

RESEARCH FELLOW (with a Ph.D. degree or equivalent experience) in the COMPUTER CENTRE, Australian National University, to take part in the work of the Centre and to undertake research in an appropriate branch of computer science—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 31).

SENIOR LECTURER or LECTURER in SOCIAL ANTHROPOLOGY, University of Cape Town—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (October 31).

CHAIR OF OPHTHALMOLOGY and EYE HEALTH at the University of Sydney, Australia—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 15).

ASSISTANT EXPERIMENTAL OFFICER (experienced in bacteriology and the usual biochemical techniques; in chromatography (paper and column); and in high voltage paper electrophoresis) in the CHEMICAL MICROBIOLOGY DEPARTMENT for research in the enzymology of milk and the behaviour of the fat globule membrane during milk processing, with special reference to cheese making—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, Berkshire, quoting Ref. 67/31.

SENIOR TECHNICIAN (preferably with background experience of histology and cytology) in the SCHOOL OF BIOLOGICAL SCIENCES, Half Moon Lane, S.E.24, for the preparation of material for electron microscopy and to attend to the day-to-day running of the microscope—The Secretary, Ref. 1118, King's College, Strand, London, W.C.2.

SENIOR TECHNICIAN I (with experience in chemical pathology) to work in the RENAL TRANSPLANT UNIT in conjunction with the Medical Unit—The House Governor, St. Mary's Hospital, Paddington, London, W.2.

## HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.  
The direct postal price per subscription for one or two copies of NATURE each week is:

## \*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire.....£14.0.0 each  
United States of America.....(by air freight) \$44 each  
Canada.....(by air freight) \$47.80 each  
Elsewhere overseas by surface mail.....£13.15.0 each

(Charge for delivery by air mail on application)

\*Shorter periods *pro rata*. (Minimum three months.)

## MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

## 12 MONTHS (52 issues and 4 indexes)

Number of Copies	G.B. & Eire	U.S.A.	Canada	Elsewhere
		(by air freight)		(surface mail)
3-5	Each £13.10.0	Each \$42	Each \$46.00	Each £13.10.0
6-11	£12.15.0	\$40	\$43.60	£12.15.0
12 or more	£12.0.0	\$38	\$41.70	£12.0.0

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)

## KEEPING OPTIONS OPEN

THE conference on the school curriculum at Cambridge at the weekend (see page 1329) is an interesting and important sign of the times, if only because it shows how the interaction between the schools and the universities is coming to occupy a central place in the interests of those concerned with educational reform. But this does not, of course, imply that the ill effects of the traditional system of specialization in the schools have not previously been recognized. For much of the past decade and for a variety of reasons, there has been a steady stream of argument in favour of reform. What has happened now is that several independent lines of argument have come together so as to make quite irresistible the case for some drastic revision of the procedures by which young people move from school to university. Is it unreasonable to hope that reform will come quickly now that the need of it is obvious?

First of all, it is important to be clear what reforms are necessary. In this connexion it is important that the British educational system is different from almost all others in the way in which young people are required from a tender age to make decisions about their future education and careers. Some schools require students to make a choice, at thirteen or fourteen, between a science course in chemistry perhaps and a course in some foreign language. But the real trouble starts in what is called the sixth form, where students with academic ambitions usually find themselves following courses in three related subjects chosen to bring success in the competition there will later be for vacant places in particular kinds of university departments. Intending scientists—even when they know that that is what they are—often find themselves in cleft sticks, having to choose between a curriculum which includes no biology and one which has no mathematics. And, although more enlightened schools now take considerable care to see that specialized courses are filled out with extras, nobody really takes this seriously, if only because competitive entry into the universities serves powerfully to concentrate attention on those parts of the curriculum which are rigorously examined. It is no joke, as Mr Carter pointed out at Cambridge, that the newer universities find themselves having deliberately to broaden the kind of education provided by the schools.

Why is this bad? It is only fair to say that fifty years ago the system was able to provide a taste of an academic education to great numbers of people for whom a university would have been quite out of the question. Now young people with the same interests (and a great many more as well) need not depend on the schools for an opportunity to study something in depth (which is not to imply that Britain is well provided with university places). Schools must

now cater for a subversive diversity of interest among the students. The result is that a secondary school system which was once a great source of strength has become almost an obstacle to the advancement of society. Within this pattern, it is no longer easy to provide the kind of education that will best serve the interests of young people. Not only are there new things to learn. It has become even more self-destructive for a young person to abandon chemistry, or French, or Shakespeare. But if young people are cramped, so is society as a whole. Talents are not fully developed and used. Square pegs finish up in round holes. Scientists are particularly concerned just now because of the suspicion that disinclination of young people to put their noses to the grindstone of sixth-form science is one of the reasons why universities are hard pressed to recruit all the students they would like (see page 1333).

So what is to be done? Some remedies are obvious. A general pattern of education up to sixteen is now an urgent need, which in itself entails that a number of practical decisions should be taken. For one thing, the study of science below sixteen should not be so obtrusive that students (and sometimes schools) find themselves having to imitate in their own timetables the names given to science departments at universities half a century ago. Plainly, somebody or some institution should undertake to develop a curriculum intended for young people in general. It is also important that British schools should pay more attention than is their present habit to the teaching of French and other foreign languages. Performance is at present patchy. And then it is clear—this was one of the themes running through the Cambridge conference—that British schools need some means of teaching mathematics in such a way as to provide young people, not only potential scientists, with a skill in the kind of mathematics which is likely to be useful in an increasingly interesting environment. Here, too, is a strong case for adventurous curriculum development, and for a pattern of studies in the sixth forms which will include some mathematics for everybody.

But man—even modern man—cannot survive on mathematics alone. What else should the sixth forms teach? The conference last week brought out clearly the dilemma in which all those who would reform the system sooner or later must find themselves. Should the objective be to design a broad curriculum and to see that all young people with similar interests are taught on much the same pattern, possibly by asking that all entrants to the universities should pass examinations in a range of subjects? Or would it be better to aim at a less oppressive load of examinations so that the schools themselves can provide a broad foundation for a modern liberal education? If

there had been a show of hands at Cambridge, broadness would probably have won the day, chiefly because any other pattern may require that students should make firm decisions on future studies two years or so before leaving school. In the circumstances, it is earnestly to be hoped that the Schools Council will not too fiercely hold to the proposals which it is considering for a sixth-form pattern in which the range of externally examined subjects is restricted, not increased. The schools are right to hope that one result would be a diminution of the pressure of examinations. The snag, of course, is that if there is not at the same time a cast iron agreement with the universities, the pressures of the competition for university places could mean more narrow specialization in the schools. Given the inertia of the system, that would be too big a risk to take.

Whatever pattern seems most desirable, however, a closer liaison between the schools and the universities is essential, chiefly (in this connexion) on matters concerned with entry to universities. There is no doubt that the continuing pressure of the selection process gives bite to the pattern of specialization in the schools, and it is also plain that, if within the British system the curriculum is to be made broader, it will be necessary for university departments to be less exacting in what they ask of newcomers. The intake will be more varied. Some new students in, say, chemistry will know less chemistry than they would at present. But this is not very much to ask. Surely it is a great confession of failure when universities confess that they cannot take young people through first degree courses unless they have gone part of the way at school. It is true that doing this might well mean extra trouble, and sometimes extra time as well, but if the schools were properly provided with broadly educative sixth-form courses, very little would be lost and enormous benefits would be won. The treaty between the schools and the universities most to be desired would be one in which both parties would agree to design some sufficiently liberal realistic curriculum for students to be able to compete for places at universities and not, as at present, for places within individual departments. A little consideration of what happens in countries other than Britain would show that such a goal need not be unattainable.

But how will all this happen? In a sense, the initiative must come from the universities, and the most immediate need is a means by which the universities can speak with one voice on admissions and curriculum. Another urgent need is some means by which the opinion and experience of those in the universities who deal day by day with problems of admissions could be brought more fully into the formation of policy. Although the Committee of Vice-Chancellors may lack the power to make decisions on behalf of all universities, it can at least make propaganda on behalf of a cause which has become of central importance to the development of British society—how to educate young people without putting them in blinkers.

## WHERE PLASTIDS COME FROM

EVEN to look at (with an electron microscope) the mitochondria and the chloroplasts found in animal and plant cells seems as if they have an existence of their own. They are, for one thing, totally enclosed within a membrane and they can be used even when extracted from their parent cells to manufacture energetic chemicals such as ATP. The suspicion that they may be semi-autonomous entities—cells within cells—was strengthened by the discovery, a few years ago, that both mitochondria and chloroplasts contain DNA. Genetic evidence for genes outside the chromosomes points in the same direction, and now there is also evidence that chloroplasts and mitochondria contain the enzymes necessary for the replication and transcription of DNA and ribosomes as well as the enzymes and other components of the cellular apparatus necessary for the manufacture of proteins. The isolation and characterization of ribosomes from mitochondria now reported by Küntzel and Noll (see page 1340) is further evidence to support the notion that mitochondria and chloroplasts are potentially autonomous. But how does it come about that ordinary cells contain entities like these?

This is the question which has led in recent years to the suggestion that both mitochondria and chloroplasts may have arisen from bacteria which were at some stage in the evolution of living cells symbiotically associated with more primitive forms. The idea has several obvious attractions. It has a certain elegance. There is also biochemical evidence to suggest that there is very little in common between the nucleotide sequences of DNA taken from mitochondria and from cell nuclei. The processes by which mitochondria and chloroplasts manufacture protein seem to resemble each other in many ways and to differ from the ways in which protein is manufactured in the cytoplasm; antibiotics such as chloramphenicol will interrupt the synthetic activity of mitochondria and of bacteria, but leave protein synthesis in the cytoplasm almost unaffected. It has also been shown that chloroplasts and bacteria both yield *in vitro* systems for synthesizing protein molecules which function most efficiently at similar ionic concentrations. In other words, there does appear to be a case for saying that the systems for synthesizing proteins which are present in mitochondria and chloroplasts have something in common with those found in bacteria.

The evidence which Küntzel and Noll have now provided is another argument of the same kind. Professor Noll and his associates have already shown that the ribosomes obtained from chloroplasts have sedimentation coefficients which are more like those measured with bacterial ribosomes than the sedimentation coefficient, which characterizes the ribosomes of the cell cytoplasm. What they have now done is to show that ribosomes from the mould *Neurospora* also belong to the bacterial class. To have done this at all is a

considerable and an important technical achievement. Kuntzel and Noll also point out that within the ribosomes of a bacterial character there is a gradation in which the ribosomes of chloroplasts and of a photosynthetic bacterium are at one end of the scale, ribosomes from the bacterium *Escherichia coli* are in the middle and in which the ribosomes from mitochondria and from the bacterium *B. licheniformis* are distinguished by the largest sedimentation coefficients. So is it possible, they ask, that there has been a progressive increase in the size of bacterial ribosomes in the course of evolution?

At this stage, of course, this evidence is not a conclusive proof that chloroplasts and mitochondria have an exogenous origin as symbiotic bacteria. Indeed, it is hard to see how it would ever be possible to be sure of the correctness of a hypothesis like that. It is also prudent to remember that there may be all kinds of reasons why a certain degree of autonomy should be delegated to mitochondria or chloroplasts by the nuclei of cells. It will help a great deal when more is known of the details of the process by which the organelles manufacture protein molecules. But even if in the long run it should turn out that the hypothesis of exogenous origin is a March hare, the chase should be stimulating and illuminating.

## SIR JOHN COCKCROFT

EVERYBODY will be sorry that Sir John Cockcroft is dead, and surprised that he was seventy. He had such a flair for being busy that there was a temptation to think that he had stopped ageing just a little short of the usual retiring age. It is only a few weeks since he stopped going to the Atomic Energy Authority once a month. Quickly, he had settled in a splendid gesture of magnanimity for being president of Pugwash. By now he would also have been president of the Liberal Party, with Asquith and Lloyd George as well as Rutherford as heritage. It would have been fascinating to see how he would have shaped as a politician, but underneath his armour of diffidence he was as tough as nails.

It was, of course, a fine notion of his to have designed a machine to produce to order the kinds of nuclear disintegrations which others had only been able to bring about with the help of fast particles from radioactive nuclei. He and T. S. Walton may have been lucky to have done—with what is now called a Cockcroft-Walton generator—something which might have needed a cyclotron instead, but that was no more than they deserved. It was extremely enterprising of them to have taken seriously some hints of Gamov's about the likelihood of a charged particle tunnelling through a potential barrier and to have recognized that half a million volts might be enough to produce interesting results when protons are flung at lithium-7. People from the north of England will say that this is

just what anybody would expect from somebody who was born in Todmorden, in that neutral zone between Lancashire and Yorkshire, but that is not the whole of it.

The truth is that Cockcroft had a flair for aiming shrewdly and with great determination at more distant goals than most people attempt. This, at any rate, is the best explanation for his particular blend of enthusiasm and doggedness. He seems, for example, to have been sure, ever since 1932, that nuclear energy would be practicable, when Rutherford was thoroughly sceptical. By the outbreak of the Second World War he was deeply involved first in building radar defences and then in the organization of the first developments of nuclear energy in Britain under the wing of the Maud Committee. His great success in working out the basis for collaboration between Britain, the United States and Canada during the visit of the Tizard Mission to the United States in 1941 was as much diplomacy as physics. Yet in a curious sense his real triumph was the Harwell Laboratory of the Atomic Energy Authority, where he won great respect for acuity, kindness, lack of side and fierce stubbornness in the face of interference or even the threat of interference from outside. This is probably the reason why his shyness with people was as much a help as a hindrance to his reputation, which has been distinguished for the best part of a generation.

## LUMP IN THE THROAT

THOSE concerned with the success—even the continuation—of the international agreements whereby there are formal exchanges of scientists between Britain and countries in Eastern Europe and China will have been downcast to learn of the melodramatic manner in which Dr V. Kachenko eventually departed from London this week (see page 1322). The danger, of course, is that what seems to have been mismanagement by the diplomats on both sides might have put in hazard the programme of exchanges as a whole. Although everybody concerned—the Foreign Office, the Home Office and the Russian Embassy in London—now seems anxious to ensure that the consequences of the affair shall not be exaggerated, it is presumably too soon to know for certain that no damage will be done. In the circumstances, it is important that the governments of Britain and the Soviet Union should fully appreciate the great value of these programmes for exchanging scientists. In the past few years they have played a crucial part in the progressive integration of science in the east and west of Europe. It is unthinkable that this process should now be interrupted. This is why it would be sensible if the unhappy incident of Dr Kachenko were taken as an opportunity for making the working of the exchanges still more informal—there is still some way to go in that direction.

## NEWS AND VIEWS

### Education in the Air

THE British Government is moving almost imperceptibly towards its aim of setting up a university of the air. The idea first saw the light of day before the 1964 election, and by 1966 had reached the status of a White Paper, *The University of the Air*. Since then it has changed its name to "The Open University", and it was formally set on its way by its most fervent and sometimes its only supporter, Miss Jennie Lee, at a meeting in London this week. It will be a while before the first students can tune in to education, however; there is much to be done, and the open university will not begin until the autumn of 1970.

What Miss Lee has done is to set up a committee to plan the open university. The committee, seventeen strong, will be chaired by Sir Peter Venables, Vice-Chancellor of the University of Birmingham, and includes among its members Sir Eric Ashby, Professor Asa Briggs, Lord Fulton, Dr Brynmor-Jones, Lord Ritchie-Calder, Dr E. W. H. Briault and Lord Goodman.

The open university will be grant-aided directly from the Department of Education and Science and will not come within the University Grants Committee. The cost of setting it up will be less than £1 million, and annual running costs are thought to be about £3-4 million. Television programmes will be broadcast on the British Broadcasting Corporation's second channel, BBC 2. Courses may also be offered on radio, but exactly how this will work is still under discussion between the BBC and the education departments. As well as television and radio, the courses will include correspondence, short residential courses, and the equipping of local centres in libraries, schools and colleges with audio-visual aids. A fee will be charged, and it is expected to be about the same as the present fee for correspondence courses. The degrees of the open university, the department says, will be guaranteed by the universities, either individually or as a consortium, and the courses will be more like the Scottish or American model than the English—credits, for example, will probably be given at the end of each year. Plainly, Sir Peter Venables and his men will have a lot to do before 1970 comes along.

### Russian Salad

FOR much of this week the British newspapers have been filled with a story which has taken readers back to the chilliest days of the cold war. Dr Vladimir Kachenko, a Russian physicist who had been working at the University of Birmingham, decided to go home. He went to the Russian Embassy in London, arriving apparently in the early hours of the morning, and was told to come back later. Later in the day an anonymous passer-by saw Dr Kachenko carried—or bundled—into

a car near the embassy. When the police were told, they raced to Heathrow Airport, surrounded the aeroplane, and took Dr Kachenko into custody. At first the British authorities said that Dr Kachenko had asked for political asylum, but 24 hours later agreed with Russian officials that he was in fact unwell and should be returned home as soon as possible. He flew back to Russia on September 19.

Nobody emerges with credit from this peculiar affair. Trouble would have been avoided if the Russian Embassy had given advance warning of the need to fly Dr Kachenko home, instead of hustling him on to the first flight in a way almost calculated to arouse suspicion. But the British authorities seem to have acted hastily, and in removing a Russian national from a Russian aeroplane may have set an embarrassing precedent. It will be sad if the affair affects the exchange agreement between the Royal Society and the Russian Academy of Sciences. The present agreement, signed in October 1965, provides for exchanges at three levels. Four highly qualified scientists from each side are exchanged each year, for about three weeks, to give lectures and to get to know the scientific institutions of the other country. Three leading scientists are exchanged for periods of up to two months, to visit institutions in the other country and to give lectures. Finally, four scientific workers from each side are exchanged annually to work in institutions in the other country for periods of up to ten months.

Dr Kachenko was one of the third group, and had been working with Professor W. F. Vinen at Birmingham on the stability of vortex lattices in superfluid liquid helium. Technically the Russian Academy of Sciences should have told the Royal Society of Dr Kachenko's departure fifteen days before he left, giving the exact date and time two days in advance, but it is unlikely that the Royal Society will complain of this, as it is eager to extend the agreement. There is no deadline for arranging this, fortunately, so there should be time for the dust to settle. The Royal Society also has formal exchanges with Bulgaria, Hungary, Rumania and China, in addition to its extensive Western European activities. The Chinese agreement seems a bit one-sided; during 1966 thirteen Chinese scientists arrived in Britain, while only two British scientists went to China.

### Advice on a Shoe-string

LAST week the Select Committee on Science and Technology got down to writing its report on the British nuclear power industry. As part of the task of gathering evidence, two sub-committees have been abroad; one, led by the chairman of the select committee, Mr Arthur Palmer, visited the United States, while the other, led by Mr David Price, visited Europe.

The European party went to Germany and Belgium, but not to Italy or France. Italy would have been particularly interesting, since it is one of the few countries to which British companies have been able to export nuclear hardware. (The Nuclear Power Group commissioned a 200 MW station at Latina in 1963.) Some members of the committee are disturbed by the modest scale on which their inquiry has been carried out, and what is regarded as a self-defeating parsimony about the expenses and the costs of employ-

ing qualified staff. Under the present arrangements, the committee can only adopt a quasi-judicial function, listening carefully to what everybody has to say and then deciding who is the most convincing. Without research staff to ferret out the facts and make independent assessments, the committee can only act by balancing assertions from one vested interest against those from another, a process which could in principle go on for ever without establishing the truth. Despite the obvious need, it is probably fair to say that staff are unlikely to be recruited unless Parliament is prepared to vote much larger sums of money to its committees. Salaries of the staff of the House of Commons are not yet adequate to ensure that people of sufficient quality are recruited.

The select committee hopes that the report on the nuclear power industry will be finished in this session of parliament, which ends on October 27. Next session the committee will be examining the defence research establishments, with particular reference to the employment by them of qualified scientific and technical staff. If the committee keeps to its practice of conducting proceedings in open session, this could be a most interesting investigation. Clearly one of the preoccupations of the committee will be whether some of the qualified people in defence research establishments would be better employed elsewhere.

## Uneven Largesse

THE annual report of the Science Research Council for 1966-67 (see *Nature*, **215**, 1215; 1967; and also page 1424, this issue) gave details of the allocation of research grants and awards for postgraduate study for the academic year 1966-67. The figures show actual numbers of studentships and total sums of money involved. Not surprisingly, Cambridge topped the list of research studentships with 333. In London, Imperial College had 248 and the London School of Economics just one. Obviously a comparison on these terms means very little, but when related to the numbers of science students the figures make more sense. All the 3,472 students at Imperial College were scientists, but SEL took only one—a mathematician.

Working from provisional figures for student populations for 1966-67, the oldest and the newest universities seem to have had best results. Oxford heads the list with one research studentship for each eight students. Essex, Warwick, Lancaster, East Anglia and Sussex all have one studentship to about 10 students, followed closely by Durham, Cambridge and Aberdeen with about one to 12. The other older universities have a ratio of one to 40, but the new technological universities come out less well. The City University (London) has only one studentship to 190 students; Brunel, Loughborough, Bradford and Heriot-Watt all lie in the one to 70-90 range and Bath heads the technological league with one to 43.

Research grants can be treated in the same way, but the resulting sums per head of the student population are slightly misleading, for large amounts of capital expenditure distort the picture. Glasgow, for example, was allotted a grant of more than £1 million, 92 per cent of its total grant, for nuclear physics, which works out at £598 per science student. Oxford tops this list with £693 per head, but 40 per cent of the £1.6 million grant was for nuclear and other physics and

once again includes a large amount of capital expenditure. Imperial College, with eggs in every basket, had the highest total grant of £2 million, which worked out at £600 per head. By comparison, £127,000 for Essex seems a small sum, but with only 230 science students this stands high at £555 per head. The medium sized middle-aged universities received sums per head ranging through the hundreds, but the range below £100 was left to the technological universities. Surrey had £105 per head, and the sum falls to £13.5 per head for the City University and £12 per head for Salford.

The SRC has stated its intention of encouraging technology, and regrets the disappearance into industry with only a first degree of many of the best students of engineering and technology. This, of course, explains the small number of postgraduates at the universities of technology. (On the other hand, the SRC is encouraging pure scientists to go into industry.) As well as awarding grants to the most promising research projects, the SRC can encourage work in what it believes to be important fields by discussing with universities the topics that will receive most favourable consideration by the grants committee.

## Soviet Splashdown

IN March 1965, the Soviet Voshkod 2 spacecraft overshoot its target area and landed in a snow covered forest in the Urals. Its crew, cosmonauts Belyev and Leonov, spent two days in the forest before rescuers reached them. Since then it has seemed probable that Russian space scientists would turn their attention towards sea recovery for manned flights, in the American pattern. A recent report in the Soviet Defence Department journal *Red Star* confirms that this is indeed happening; Russian cosmonauts are now undergoing training for sea recovery. The same report reveals that Leonov nearly suffered a fatal accident during training—his parachute failed to open until he was a few hundred feet above the ground.

Landing over water would not have saved the life of Colonel Komarov in the April Soyuz 1 accident. When the parachutes fail, water is no softer than land at great speeds. But sea recovery would offer the Russians several advantages. At present the Russian space flying season is restricted to 5-6 months in the summer, and sea recovery would make it possible to extend the season. It would also prepare the way for the return trip from the Moon, when it is likely to be difficult for the cosmonauts to land within the normal Russian recovery area. The two-thirds of the globe covered by water offers a much larger target, although clearly the pilot will be hoping to land somewhere near a recovery ship.

Such a radical change of technique will not be achieved by pressing a switch. It is possible that the new flatter orbit, at an inclination of 51°, which was flown by Soyuz 1 and by four Cosmos recoverable satellites during the previous six months, was an intermediate stage in the shift. For sea recovery, a fleet equipped with sophisticated radio aids would have to be deployed, but perhaps the United States forces in the Pacific could be relied on to pick up a straying cosmonaut—the new space treaty guarantees the return of space travellers to their country of origin.

## Gentle Persuasion

from a Correspondent

IN an effort to disabuse PhD students of the notion that academic research is the only respectable outcome of a scientific education, the Science Research Council and the Careers Research and Advisory Centre have just organized an eight day summer school at University College, Oxford, in association with the London Business School. The aim was to introduce postgraduate students to the many different types of industrial and administrative problems, and to show that these are stimulating and as worthy of attention as more academic work. The presence of 50 PhDs from industry gave the postgraduate students the opportunity for discussing informally aspects of careers in industry and administration.

Extensive use was made of case studies of actual companies and group exercise methods involving the full participation of the students. The contents of the course were generally completely new to the postgraduate students, and included topics as diverse as operational research, the financial problems of capital project appraisals and systematic management development. Aspects of business not usually looked on favourably by postgraduates—marketing, for example—were made to seem interesting. Demonstrations of modern techniques such as operational research and systems analysis, which help the manager in making decisions, won an attentive audience—although one which frequently asked to what extent these scientific methods are actually applied in British industry.

The highlight of the week for the majority of the students was a business game—an attempt to simulate a dynamic business situation for a number of competing teams made up of students representing the senior executives of the companies concerned. As well as giving the participants a chance to test their management acumen, the game provided an understanding of the workings of a company and an appreciation of the conflicts which can arise in the board room.

The course was not in any sense a careers convention and there was no recruiting by specific firms. It succeeded in providing a valuable insight into the mechanisms of business and a glimpse of the administrative skills required of a successful manager. Many of the PhD students remained sceptical, however. Doubts were expressed whether anyone entering a large company through a research and development department, as the majority of those present would do, could ever rise to a senior executive position. Beliefs like this, which have developed over several years in an academic climate, cannot be altered so easily, and a first impression of the course is that it may have hardened attitudes rather than have changed them.

The organizers are wisely being cautious in judging the success of their venture. A questionnaire designed to discover attitudes to industry was filled in by all the participants before and after the summer school and will be completed again in several months, when the effects of the course will be more readily discernible. Until the results are known it will be too early to draw any definite conclusions.

## Informed Chemists

ALL five hundred chemistry PhD students in their final year at British universities who are being supported

by an SRC grant are to take part in an experiment with the Chemical Society's Research Unit in Information Dissemination and Retrieval at the University of Nottingham. The unit will provide the chemists with relevant references from the literature, which are selected by computer so that the value of the service can be assessed and changes made if necessary. Six liaison officers, who are themselves chemists, from the Chelsea College of Science and Technology, and the universities of Edinburgh, Oxford, London, Warwick and York, have been appointed to provide a link between the students and the unit.

The liaison officers will meet the heads of the university chemistry departments in their areas next month to explain the scheme. They will then meet the students and, using the references the students have found useful, will work out a reference "profile" for each student to be fed into the unit's computer. The computer will then give the student a list of up to date references relevant to his line of research every two weeks. The liaison officers will meet the students six or seven times during the year to make sure that they are getting a suitable service. It is hoped that the service will give the students a good introduction to the use of mechanized information services and that the experience gained will be spread widely when the students take up employment in government, industrial and university laboratories.

The Office for Scientific and Technical Information, which is organizing this project, is also giving a grant of £56,000 to the Chemical Society's Unit to extend its programme of work for the next two years. The research unit, which gave a demonstration at the Chemical Society's autumn meeting in Durham this week, is financed jointly by the Chemical Society and the Office of Scientific and Technical Information. During the past nine months it has regularly provided about 250 people in various government, industrial and university research laboratories with lists of titles of research papers. The titles have been selected by a computer comparing a machine readable statement of their research interests with magnetic tape versions of two Chemical Abstracts Service publications, *Chemical Titles* and *Chemical Biological Activities*.

## Dispensing with Meteorologists

THE Proceedings of the World Meteorological Organization's Conference on Automatic Weather Stations, held in Geneva a year ago, have now been published. In his opening statement, Mr D. A. Davies, secretary-general of WMO, said that studies had shown that while observational satellites undoubtedly marked a turning point in meteorology, the full benefits would only be reaped if a complementary system for observing the atmosphere from the Earth's surface itself was available. The problems of establishing and maintaining an adequate network of observing stations, especially in the uninhabited regions, meant that automatic weather stations would become increasingly important.

In a report on US Weather Bureau Automatic Stations, Mr A. N. Hill said that the US Weather Bureau had a large number of "co-operative observers" who took daily readings, but because of increased personal mobility they were becoming reluctant to give daily readings and for this reason would need to be replaced. A simple data logger was required and

the development of one had begun in 1966 and was expected to take one and a half to two years.

He also outlined plans for a Co-operative Hurricane Reporting Network, CHURN, of about one hundred stations. Small automatic weather stations would record wind speed, wind direction, temperature and pressure, and report them to an area collecting station where the information would be put on teletypewriters as required. Mr Hill said that in the vast forested areas of the US there was a great need for more meteorological data—particularly when there was a danger of forest fires.

At the conference the various forms of power supply for automatic weather stations were reviewed. These included air depolarized primary batteries, wind driven generators supported by either lead-acid or nickel-cadmium batteries, dry batteries, propane heated thermoelectric generators with secondary batteries, nickel-cadmium batteries charged by a propane fuelled generator, and thermoelectric generators heated by radioisotopes. The radioisotope generators were considered rather expensive, but because of their long life it was hoped that their capital cost could be reduced to make them an economic proposition.

The conference also considered the possibility of introducing automatic or semi-automatic equipment for merchant ships. Although there are some 4,500 merchant ships which supply data, of which perhaps 3,000 should be at sea and reporting weather conditions at any one time, a one day count conducted by WMO on July 1, 1963, revealed that only about 800 ships had reported.

## Bargain Journals

THE Institute of Metals and the Institution of Metallurgists set up a joint trust at the beginning of this year, and among its functions is the publication of two journals—the monthly *Metals and Materials* and the bi-monthly *Metal Science Journal*. The former contains topical articles as well as more esoteric reviews of scientific development and will be issued free to all members of the Institution of Metallurgists. The *Metal Science Journal* will be available to members for thirty shillings a year. At the same time, the Institution has made special regulations to allow science teachers without qualifications in metallurgy to take part in its conferences and to receive its magazines. The annual subscription of the Institution is £3 10s. or less, and members will be able to apply for tax relief on this as payments made to a professional society. A year's subscription to the two journals would cost a non-member more than £20, so that members have good reason to congratulate themselves on a bargain.

## Doing Sums Again

A SURVEY carried out among students of adult education classes has revealed some interesting facts about the retention of mathematics learnt at school. The survey was carried out by Mr Harry Frost, an extension staff lecturer in physical sciences at the University of London, in 1962. The results have now been published (*University of London Extra-Mural Studies Occasional Papers*, No. 1, 4s. 6d.). Adult students in various parts

of England and a small control group of staff from Senate House, University of London, were asked to answer a test paper of thirty-seven questions of the type which they would have faced between the junior school and scholarship level. In marking the papers, credit was given for method rather than numerical correctness, although there was plenty of indication that many of the students were beset with the schoolboy worry of "getting their sums right". Slightly more than half of the papers were returned by both student sample and control group. Willingness to return papers seemed to reflect personality rather than ability, but there was some tendency for weak mathematicians to be reluctant.

Men with a residual mathematical age of less than ten—based on the teaching ages assumed to correspond to the questions—were much fewer than women with such a low residual mathematical age. This seems to indicate inferior retention of mathematics by the women students, few of whom are required by their work to think quantitatively. In the control group this difference between the sexes was less pronounced; in this case the women had not recently spent several years in mathematically undemanding home duties.

Retention—the ratio of the age at which mathematical education ended to the residual mathematical age—is inversely related to education: the more there is to forget, the more is forgotten. The number of years between the end of mathematical education and taking the test is not significant. Of the students whose mathematical education ended forty years ago, 78 per cent still retain 70 per cent of their mathematics. The oldest participant finished his mathematics education seventy years ago and his retention was 87 per cent. Regular use of mathematics is, however, more significant; few people retain mathematical ability beyond that of the fourth form of the grammar school unless they regularly use the subject. People clearly retain more mathematics than they say they do, and even students with a minimum of mathematics education who use the subject very little could be expected to have a knowledge above the standard of the 11-plus examination.

Thus most of the students in the sample should have been capable of understanding and appreciating the adult science courses, which have been organized to present scientific ideas without jargon and without mathematics. Within the survey sample, however, most people who joined scientific classes had more than sufficient mathematics, and those without an "excess" of mathematical knowledge stayed away. If the popularization of science is to be successful it will be necessary to convince those people who suppose that they could never appreciate science that they are wrong, and that science is not inextricably bound up with numbers.

## Scientific Conservation

IN 1960, the cave paintings at Lascaux, which had survived since the Stone Age, began to show signs of a green mould. The delicate climate of the cave had been affected by the constant flow of visitors, and by the need to install machinery to control the ventilation. The cave was closed to visitors. Progressively more ruthless attacks on the mould with antibiotics seemed to have solved the problem, but in 1964 a new danger

threatened. The calcite formations on which the paintings are supported began to spread, covering the walls with a white surface. This, it was decided, could only be prevented by the most rigorous control of the temperature, humidity and carbon dioxide content of the cave. It is not yet clear that this will ever be compatible with the desire to re-open the cave to the public.

The problems at Lascaux may be the most extreme that conservators have faced in recent years, but they indicate some general principles. These were discussed at a conference held this week in London by the International Institute for Conservation of Historic and Artistic Works. Added to the simple problems of conservation—which are severe enough to make conservators wonder how anything at all has survived—there are hazards in the increasing tendency for works of art to be transported about the world from exhibition to exhibition. The floods in Florence and Venice are another unpredictable hazard in which conservators are involved.

Mr Thomas H. Carver, who is Assistant Director of the Rose Art Museum in Massachusetts, defined the problem of atmospheric pollutants. Since most large art galleries are in cities, the air is full of impurities. Even within the museum, the air is likely to be contaminated—from visitors, construction projects within the museum—or indeed carried in from outside. Thus all the air within the museum must be properly filtered. Light is another problem. Ultra-violet light, either from the Sun or from fluorescent tubes, can cause irreparable harm to paintings. It is necessary to balance the need for enough light against the danger of damaging pictures by supplying too much—which is why the Leonardo cartoon in the National Gallery in London spends its life in reverential gloom. Variations of humidity, particularly those which happen suddenly,

Green mould on the walls of the cave at Lascaux.

are one of the most destructive forces for works of art; while humans are most comfortable at humidities of 30–35 per cent, paintings need 45–55 per cent. With a scientific approach to these problems, conservators hope that the preservation of works of art can be guaranteed. In the past, more often than not, they have survived by sheer good fortune.

## Disappointing Shower

from an Astronomy Correspondent

It is now clear that the return of the Leonid meteor shower in November last year, eagerly awaited, was a disappointment to most observers in Britain. In the United States, on the other hand, the display seems to have compared well with the Leonid meteor storms of the nineteenth century.

Interest in the Leonids—and in meteors in general—was awakened by the great display over North America on the night of November 12–13, 1833. The frequency of meteors was then estimated to be “about half that of flakes of snow in an average snowstorm”. This spectacle recalled a similar event over South America observed by the explorer Alexander von Humboldt on November 11, 1799, who saw “thousands of meteors and fireballs moving regularly from north to south with no part of the sky so large as twice the Moon’s diameter not filled each instant by meteors”. Records of the shower can be traced back to A.D. 902, brilliant displays occurring at intervals of 33 or 34 years.

As expected, there was a magnificent show in 1866, but the recurrences of 1899 and 1932 were weak, possibly because of perturbations of the stream by close approaches to Saturn and Jupiter in the meantime. In the early 1960s, the zenithal hourly rate of Leonid meteors began to rise from 6 up to 30 in 1964 and 50 in 1965, and it looked as if 1966 would be a good year. However, descriptions of the shower on the morning of November 17 by observers reporting to the American journal, *Sky and Telescope* (33, 4; 1967), exceeded the predictions of the most confident astronomers.

Egyptian cat with severe bronze disease. This is caused by soluble salts in the layers of early bronzes; when exposed to moisture, green spots appear on the surface.

Where sky conditions were favourable, observers in the south-western United States saw too many meteors to make a direct count as the shower reached its climax, at 11.55 universal time. The burst of activity started at about 11.30 and lasted for an hour. A group on Kitt Peak, Arizona, estimated that 40 meteors could be seen in a one-second sweep of the observer's head at the peak of the shower, with more than 1,000 meteors a minute from 11.30 to 12.30 (4.30 to 5.30 a.m. mountain standard time). Similar reports, estimating tens of meteors per second at peak activity, came from California, Colorado, New Mexico and Texas. Accounts from the Atlantic states also indicate heavy activity, but are not quite so impressive since dawn began to interfere while the rate was still increasing.

Meteor showers are believed to be the debris of comets, and the 33 year periodicity of the Leonids is caused by an intense concentration of meteoric particles near the point on the orbit where the parent comet is located. The non-appearance of the display over Britain can be attributed to the comparatively small size of this swarm, but it is evident that the Leonids are still capable of giving a brilliant display.

## Mechanism of Polarity

from our Cell Biology Correspondent

As Imamoto and Yanofsky (*J. Mol. Biol.*, **28**, 1 and 24; 1967) have now shown, polar mutations cause failure in transcription; genetic polarity is not caused exclusively by defects in translation.

Transcription of polycistronic operons, like the tryptophan and lactose operons of *E. coli*, produces a single mRNA molecule containing information for several enzymes. Amber, ochre and frame-shift but not mis-sense mutations in such operons may show polarity; a polar mutation prevents the expression of the cistron in which it occurs and also leads to reduced levels of the enzymes specified by the subsequent, operator-distal, cistrons of the operon. Not all polar mutations in any one cistron show the same degree of polarity; in the *lac* operon, for example, there is a continuous gradient of polarity across the  $\beta$  galactosidase cistron from the very strongly polar mutations at the 5', N terminal end of the cistron to the very weakly polar mutations at the 3', C terminal end.

How do amber and ochre mutations cause polarity? There are three possibilities: (1) by reducing the frequency of the translation of regions of mRNA beyond the nonsense codon; (2) by preventing transcription of mRNA from DNA after the nonsense codon; or (3) by a combination of both these processes. Because suppressor gene transfer RNA prevents chain termination by amber and ochre codons and also relieves polarity, it seemed that polarity might result from defects in translation, and several groups have devised purely translational models for polarity.

Attardi *et al.* (1963), however, found that extremely polar mutants of the *E. coli* operon fail to make *lac*-mRNA; perhaps polar mutants prevent transcription. Using a hybridization technique to detect *tryp*-mRNA, Imamoto and Yanofsky have now shown that strains of *E. coli* with strongly polar mutations in the tryptophan operon do indeed make less *tryp*-mRNA than identically treated wild type cells

or mis-sense mutants. The *tryp*-mRNA molecules of the polar mutants are short; they lack the regions that are normally transcribed from the DNA beyond (operator distal) the site of the polar mutation. Furthermore, the size of the predominant *tryp*-mRNA species in different mutants increases in relation to the genetic distance between the beginning of the first cistron of the operon and the site of the mutation.

Estimates of the relative proportions of complete and short mRNA molecules made by the different mutants correlate fairly well with their previously observed translational polarity; for example, a mutant with 14 per cent translational polarity—it makes only 14 per cent wild type levels of enzymes specified by the cistrons following the mutated cistron—made only 10 per cent complete *tryp*-mRNA molecules and 90 per cent short molecules. Pulse labelling of the *tryp*-mRNA as it is synthesized revealed that the mutants make normal numbers of mRNA molecules and that the short molecules are not produced by degradation of complete molecules. Polarity, therefore, certainly involves and may even be caused entirely by failure in transcription.

How can this finding be reconciled with evidence that polarity is a translational phenomenon? A non-sense codon itself is not a signal to RNA polymerase to stop transcription, and genetic translation and transcription are closely coupled; ribosomes somehow regulate mRNA synthesis (see *Nature*, **214**, 228; 1967). Hence Imamoto and Yanofsky suggest the continued transcription of DNA by RNA polymerase depends on the normal movement of ribosomes translating that part of the mRNA molecule already synthesized. If this ribosome movement is impeded by a nonsense mutation and a subsequent untranslatable region of mRNA, then the greater the distance between the nonsense codon and the initiation site of the next cistron in the DNA being transcribed the lower the probability that RNA polymerase will continue transcription and so the mRNA molecule will be terminated.

## Protean Proteins

from our Molecular Biology Correspondent

It is interesting to speculate whether the native state of a protein represents a single uniquely stable conformation, or whether it is better regarded as one of a number of states occupying potential energy minima, between which transitions can occur in response to environmental adjustments. The proteins trypsin and trypsinogen have recently been subjected to careful scrutiny by several groups working in France, and the results which have been reported have a general bearing on this question.

Lazdunski and Delaage (*Biochim. Biophys. Acta*, **140**, 417; 1967) have studied pH-dependent conformational transitions in both the enzyme and zymogen, and have observed the existence of three reversible equilibria, linking four definable conformational states. The changes are followed on the one hand by difference spectra, which reflect the state of exposure of tyrosine and tryptophan residues, and on the other by optical rotation. Three at least of the observed isomeric states appear not to be denatured forms, in the sense that the protein retains in each case characteristics

of globular structures, undergoes a transition to an unfolded form on heating, and in two of the states is protected against denaturation by specific inhibitors. (That is to say, the active centre remains intact.) There is a broad correspondence between these various states in the enzyme and zymogen, and in both cases phase diagrams have been constructed, which define the stability ranges of the various native and denatured forms with respect to *pH* and temperature.

The same authors (Delaage and Lazdunski, *Biochem. Biophys. Res. Commun.*, **28**, 390; 1967) have also examined the binding of calcium ions—which are known to have an influence on the activation of the zymogen by directing the hydrolysis of the correct peptide bond and suppressing adventitious cleavage. There is evidence that both possess a specific calcium-binding site, which is strong in one of the conformational states, weak in another and absent in the remaining two. The one state (that prevailing at neutral *pH*) is therefore strongly stabilized by calcium, both with respect to transitions to other isomers, and denaturation by heat or urea. The observation that the site is still present after conversion of the zymogen to the enzyme suggests some rather extensive similarities of conformation. A second, and weaker, calcium binding site is present only in the zymogen, and is believed to lie in the peptide which is cleaved on activation.

A further study, of the interaction of trypsin with inhibitors and substrates, comes from D'Albis and Béchet (*Biochim. Biophys. Acta*, **140**, 435; 1967), who find that interaction occurs even at relative extremes of *pH*. This, using the approach of Delaage and Lazdunski, may presumably be seen in terms of the stabilization by the ligands of those isomeric states to which they bind. The curious observation is reported that one tyrosine residue becomes unavailable for titration when an inhibitor is present (in addition to the five already masked), until the protein is unfolded. This suggests a structural change on binding the inhibitor. There are also some changes in optical rotatory dispersion, which may be interpreted in terms of small conformation changes (in accordance with the "induced fit" notion). On the other hand, because the inhibitor contains a phenyl chromophore, which may well become optically active on binding, a new Cotton effect could also explain the result observed.

A further current article (Labouesse and Gervais, *Europ. J. Biochem.*, **2**, 215; 1967) clarifies a rather ambiguous situation, relating to the acetylation of trypsin and its effect on the enzymatic activity. Conditions have been established for the preparation of a derivative, in which all the  $\epsilon$ -amino groups, but not the tyrosines or the  $\alpha$ -amino group, are acetylated. It is confirmed that both the lysines and tyrosines can be modified without destroying the activity, and indeed acetylation of tyrosines is found to enhance the estero-lytic activity. The form in which only the  $\epsilon$ -amino groups are acetylated has normal activity. The possible involvement of the terminal amino group in the active site remains unestablished.

## Beards and Bugs

from our Microbiology Correspondent

A SOMEWHAT UNUSUAL piece of research has been reported recently by a team of microbiologists working

in the Industrial Health and Safety Office at Fort Detrick in Maryland. These workers (Barbeito, Mathews and Taylor, *Appl. Microbiol.*, **15**, 899; 1967) are concerned by the revival of beards among persons working with pathogenic micro-organisms and have investigated the hypothesis that a bearded man provides a risk of infection if his beard becomes contaminated in the laboratory. To test this hypothesis, a group of volunteers had their beards sprayed with cultures of non-infective *Serratia marcescens* and *Bacillus subtilis* var. *niger*, pigmented bacteria which are easily picked out in sampling programmes. With proper regard for their colleagues, Barbeito and co-workers used a bearded mannequin to study the transmission of Newcastle virus disease (*Clostridium botulinum* type A toxin) by beards, with chickens and guinea-pigs as test animals.

Sampling of contaminated beards was made by various means—swabs, membrane filters, agar impressions and saline rinses. In addition, beards were shorn and suspended in nutrient broth. Clean shaven subjects acted as controls and the effect of washing with a disinfectant soap was estimated for both groups. Comparison of the sampling procedures demonstrated that shorn beards blended in broth produced greater numbers of bacteria and that the other methods were likely to underestimate potential infection doses which may result from contact with unwashed beards. Here the investigators emphasize that several diseases are known for which the inhaled human infection dose is about ten microbes. Beards clearly held bacteria more effectively than skin even after soaping and rinsing. It is comforting to note, however, that in order to recover bacteria from unwashed beards it was necessary to apply populations of  $10^4$ – $10^5$ , and laboratory contamination of this magnitude is unlikely to occur without the subject inhaling sufficient organisms to produce an illness. Thus beard-infection of close associates appears feasible only when the wearer has a recognizable accident or is subjected to regular doses of microbial aerosols, as might arise when carrying out a repetitive technique. On the other hand, results of experiments with NDV and the botulinum toxin indicate that contamination within the range of likely accidental beard contamination would create a serious human health hazard.

Interesting and salutary as the results of these trials are, one must keep in mind the fact that very many more people working with pathogens have hair on the top of their heads than on their faces and the issues raised in connexion with beards are surely more widely applicable. Clothing is another potential agency of dissemination and several reports have appeared on the persistence of micro-organisms, especially viruses, on clothing fabrics. To combat this, searches are being made for effective viricidal agents with which to impregnate fabrics. Sidwell, Dixon and McNeil (*Appl. Microbiol.*, **15**, 921; 1967) have illustrated the efficacy of treating fabrics with quaternary ammonium compounds or triazone resin in inactivating or greatly reducing the persistence of vaccinia and polio viruses on a variety of woollen and cotton materials. The treatment of fabrics to render them self-sanitizing is an attractive proposition, particularly when they are used in places liable to contamination by pathogenic micro-organisms.

# Towards a Broader Curriculum

A conference on educational problems concerned with the transition from school to university was held at Gonville and Caius College, Cambridge, on September 15-16 at the initiative of Sir Nevill Mott and with the sponsorship of *Nature*. Several independent lines of argument led the participants to agree that a broader curriculum in the sixth form would be desirable. The report of the proceedings which follows, prepared by the staff of *Nature*, is intended to show how this conclusion was arrived at and to suggest some of the problems which now call for attention.

SIR NEVILL MOTT begins by saying that the conference has its origins in the discussions within the Schools Council of how the sixth form curriculum may be reorganized. The idea, current a year ago, that there may be major and minor courses in the sixth form has now been dropped. Instead, there are discussions about a scheme intended to limit the externally examined subjects studied in the sixth form. But there is no assurance that the result will be a real broadening of the sixth form curriculum—it could be the opposite. And yet the objective, crucial for science and technology, is a broadening of the curriculum. We believe it is an educational must that the age of choice should be delayed for as long as possible. And from that all kinds of other issues follow. Should there be a fourth year at the university for a great many people? How much would this cost?

Professor Allanson says the most serious problem is that decisions about future courses and careers now have to be made at a ridiculously early age. He knows the Schools Council has had this in the forefront of its mind, but doubts whether it has given it a high enough priority. Has it taken account of the complicated patterns in the school curriculum, the larger sixth forms and the wider range of ability and interest in them? And he is afraid we forget that the whole world is not composed of scientists.

Miss Miles thinks that her problems may be easier because girls' schools are more accustomed to a liberal curriculum. She deplores the artificial distinction between things which are examined and things which are not examined. At present, she says, the curriculum is broad until the age of sixteen; after that it becomes specialized, and then we have to make great contortions to bring back the general subjects which have been dropped. Why not, instead, learn and go on learning?

Mr Jennings agrees that the postponement of decisions by pupils is desirable, but thinks the Schools Council has been maligned. What is this talk about compulsory subjects? To Professor Keohane the crucial question is what kind of education should be provided throughout the educational system? Only fear of a shortage of scientists has brought us together, which is a pity. So far as science is concerned it is wrong to have O-levels in separate subjects—physics, chemistry and biology, for example. The chief problem is that people are required to take out options at thirteen or fourteen. He wants a broader education up to sixteen and thinks that it would then be permissible in the sixth form to have broad courses in science such as the Nuffield Foundation's physical science course.

Professor Lauwerys agrees that this is a good starting point. It is a question of when, between sixteen and thirty, options should be introduced. In the sixth form, he thinks that there should be a broader course of studies—something like the old matriculation exam for entrance to universities—mathematics, the mother tongue, a

foreign language and two others. Professor Elton goes one better—there ought to be a general education up to eighteen.

Professor Elvin stands out against this line of argument. A three year degree may be unusual, but the Robbins Report found it an advantage, and in any case some 20 per cent of British undergraduates spend four and not three years on their studies. He wants to encourage this tendency, but would not like to see it become universal overnight. And he would preserve the way in which the sixth forms in most British grammar schools prepare

- L. ROSENHEAD, *Professor of Applied Mathematics, University of Liverpool.*
- S. J. TESTER, *Lecturer in Classics, University of Bristol.*
- MRS SHIRLEY WILLIAMS, *MP, Minister of State for Education and Science (for one session).*

people for universities. For him, a three year undergraduate course preceded by three years in the sixth form is the best. It could even be cheaper and could accord with the trend of social fashion to stay longer at school which the Robbins Committee underestimated. (Mr Christopher remarks that in his experience the inclinations of young people are going the other way.)

But are the schools just prep schools for universities? This is what Mr Tester wants to know. He wants a system in which anybody who leaves school at sixteen is as well educated as one who leaves at eighteen. He wants schools to be concerned with the whole education of students. And he thinks it does not matter if schools neglect to prepare students for particular university courses, for he does not believe there is a subject which cannot be taught at university in three years—given a basis in mathematics or linguistics. (Tester is not the only one to single out the chemists for being the laggards.) He emphasizes that there is nothing wrong with specialization as such—indeed, it is virtuous as well as unavoidable. He disputes the view that the logical structure of the sciences makes it possible for people to leave them and impossible to come back—nothing is more logical than the classical languages. And he wants to know why the teaching of science should be dominated by this sacred cow of the laboratory. But Professor Allanson does not believe that he could produce an electrical engineer in three years without some A-level studies in experimental science.

Mr Price says that the real trouble is the belief that schools are really meant as miniature universities—those who teach in them are university lecturers *manqués*. This is why there is specialization—the teachers like it that way. He does not think that things will be right until non-graduates are teaching in the schools in greater numbers.

Dr Nicol argues that the educational system should be looked at as a whole. We are asking how the sixth and seventh years in school are to be restructured. This cannot be done without asking about the structure of further educational training. The great need is to strengthen the tenuous links between schools and universities and to decide what is educationally desirable in both. What, for example, should be the role of postgraduate teaching? And is the honours school worth keeping?

Professor Hoselitz says that schools should not be expected to provide university courses, and people from outside should not go to the schools expecting to give advice which is not really appropriate. The scientists have made a mistake by putting science on a pedestal. It will be better to teach children what the world they live in is really like—that is how to get more scientists in the long run.

Professor Rosenhead pleads that the schools and the education system as a whole must be organized for flexibility. He asks that the goals of the education system should be chosen by trying to assess what society is going to be like twenty years from now. Business men have done better than educationists by making deliberate attempts to find out what life is going to be like for young people in A.D. 2000, and the schools have been separated from the universities, which is bad for the universities and wrong for the schools. Is it not possible to make both parts of the system work together? And Professor Rosenhead emphasizes that though it is desirable to defer choices, it is also necessary for young people to make up their minds on important matters such as their careers before they reach the grave.

Mr Carter reflects that a great many of the new universities are trying to provide students with a broader education. How odd it is that we have an educational system which makes people specialize between fourteen and eighteen and then has to have universities with general courses where people have to go back on their specialization. Should it not, Carter asks, be the other

way around? He is also worried that what the Schools Council is proposing is an organic change in this system which will still leave Britain different from the rest of the world.

He asks for a more thorough examination of the whole question of the transition from school to university. There are all kinds of practical questions to be settled. When, for example, should the transition from schools to universities take place? Should it be eighteen, as now, or seventeen or even twenty? And for that matter, why should there always be either 24 or 36 weeks in the university year? Why should there be three terms in the year? Why even should there be an integral number of years in the course? These are the kinds of question to be asked.

But if the universities influence the schools, they are themselves influenced by the needs of professional bodies. The great variety of careers in engineering, and the need to prepare students for all of them, provides a safeguard. But how can students be selected by universities? Professor Diamond believes that mathematics at A-level is the best indicator of quality—he is not worried if a student lacks an A-level pass in physics, but continues to ask for it because it is the usual thing to do. Mathematics is better suited to the examinations pattern, and is frequently better taught than physics. For this, the dull A-level physics papers must take some of the blame.

But it is not only the numbers of A-levels and the quality of the passes gained that are important. Professor Mitchell believes that it is possible to establish the content of courses by first deciding what students taking careers in science and technology are going to need at the age of twenty-one. This is particularly true in scientific subjects where factual knowledge is important in helping to communicate concepts, and it should be possible to determine what students should know in order to make an effective contribution at that age. The schools are shielded from the demands on the output of the system by the universities, but even universities should not feel obliged to provide all the highly specialized technology which industry needs—industry itself has a part to play in specialist training. If mathematics is to be a compulsory subject for scientific entrants, it must be taught at school as seen in action through engineering, chemistry and physics.

How important is experimental work? Mr Tester denies that he is opposed to learning by doing, but he does not believe that present practical courses are an effective means of providing this. If schoolchildren are properly taught they can go on to read either science or the humanities at university. Mr Elvin disagrees. Science and the humanities employ different modes of discourse. In saying "My love is like a red red rose", it is clear that the context is not botanical. Studies in science and in the humanities develop in different ways. But if this is so, Tester argues, why should children not acquire the language of both in the sixth form?

Mr Morrison suggests that we need a treaty between the schools and the universities to define the responsibilities of each. Morrison believes that this would avoid the depression and boredom which afflict history students faced for the fourth time with study of the Tudors. The older universities have an even heavier responsibility—their scholarship examinations make schools do university work two years before students actually reach university. Mr Jennings agrees that this can lead to disillusion.

Where is the opposition to change? Mr Tester believes that it is in the schools and particularly the grammar schools. What happens when you try to reform the syllabus? The opposition comes from school teachers who fear that their ability to get their pupils through examinations will be lost if they allow the syllabus to change. As Mr McMullen puts it, examinations are not chains round the teachers' necks, but their feather beds.

Mr Jennings feels that students are similarly inclined.

For most of them, the motivation is the desire for a training which will guarantee a comfortable job. Far from welcoming a broad curriculum, pupils prefer the straitjacket of specialization which gives them such good support. And Jennings utters a solemn warning—advances in education can only be bought at the cost of accepting dictation from above.

Then now should school and university education be reorganized in order to take advantage of a wider curriculum? Mr Elvin begins by putting great emphasis on the difference between school and university education, in order to ensure that teachers do what they are best at. Until the age of sixteen, he thinks, a certain number of subjects should be compulsory—or nearly so. These should include mathematics, the mother tongue, one science subject, perhaps one foreign language, and history and geography. After sixteen, young people no longer wish to continue in schools they have known since the age of eleven, and it is here that sixth form colleges can provide a new element in the educational pattern. Some young people may then be happy with a broad curriculum, but others may actually prefer to become specialists, and the structure must incorporate a measure of flexibility to allow for this. Within the large sixth forms or sixth form colleges could be concentrated the best and most scholarly teachers. For most people, however, the sixth form college is not a welcome solution.

Professor Elton argues that if the education of young people is to take an extra year, it should be spent in universities, that this should be at the postgraduate level and that universities should be willing to accept a more restricted first degree.

Mr Morrison has an entirely new suggestion to make. What is needed is an examination in five subjects which should include English, mathematics, physical or biological sciences, one foreign language and history or geography. Certainly it could not be called A-level but might represent a sort of junior *abitur* or *baccalaureat*. The form of the examination should be the basis of a treaty between the schools and the universities in which each party could recognize its responsibility for maintaining a broad curriculum.

Sir Nevill Mott is sure that dons believe in the need for a wider education, and is therefore puzzled to know why in practice they tend to behave as if they do not. What is needed is a structure which would enable universities to make just choices between the specialist and the generalist. Mr Tester is doubtful that the Morrison scheme would achieve this. What matters in selection procedure is not the principles, but the practice. There would be a real danger that new forms of specialization would be grafted on to the Morrison scheme. But Miss Miles is more hopeful. The scheme would be much less dangerous than the Schools Council scheme, or something like it. The Morrison scheme would not necessarily rule out a degree of specialization; children would take all five subjects but could specialize in some of them.

But how to discover what the universities think? Dr Nicol sees a need for a representative body. Professor Allanson believes the body already exists—it is the Standing Conference on University Entrance. Everybody agrees that the difficulties may never entirely be resolved while pressure on university places remains. While nobody denies that a broad curriculum is educationally desirable, Mr Tester doubts whether universities would be prepared to ignore the student who has specialized in the subject he wishes to read at university. Would the Morrison proposals really introduce compulsory breadth into university entrance? Professor Allanson says that perhaps the best solution would be for the universities to adopt the Morrison proposals together with Mr Tester's suggestion that studies beyond the Morrison level should be ignored for the purposes of selection.

But Mr Morrison says that his scheme is really only one attempt to give a little reality to the general view that

options should be kept open as long as possible. He acknowledges that if you keep five subjects instead of three in the sixth form, the standards of entrance will be lower. But schools should offer five subjects and should not expect to teach more specialized courses than those on offer to everybody. To be sure, it would be entirely proper for those who are convinced already that they know what to do at university to drop one of the subjects—but not both—on the side which interests them least. And he says that it is essential to find some way of arranging for a link between schools and universities and some way of negotiating a treaty between them.

This raises all kinds of criticisms, some practical, some concerned with principle. Keohane is not sure that a treaty between the universities and the schools can last. Nicol considers the real need is to reach some kind of agreement at the level of admissions tutors in universities. But there are a thousand of them—what chance is there of keeping them all equally well informed?

Mr Dancy raises a discordant note. He says that if you lay it down that no subject may be studied by anybody beyond a certain level, and if this amounts to simply five teaching periods every week, the best teachers in schools will say their job is not worth doing and will clear out of education altogether. He says that one of the glories of English education is the way in which sixth formers are dealt with in British secondary schools. If he were forced to choose between a broad curriculum of the kind which Morrison has suggested, with five teaching periods a week for the academic subjects, and a system like the one the Schools Council has devised, he would settle for the latter.

To Professor Hoselitz, this is a kind of heresy. It ought to be a challenge to teachers to have to teach academic subjects which at present take seven or eight periods a week in a mere five. There is no reason why this should not be done. After a number of attempts to construct timetables, Sir Nevill Mott says he wants above all an A-level with useful mathematics.

Professor Diamond is uneasy about the assumption that changes in the schools will make necessary a four year university course. As far as he is concerned, what matters most is that people should go into industry as quickly as possible. This does not mean that a broader curriculum in the sixth form is a bad thing, but it is important that it should not impede the transition from university into industry. But we have to have a broad curriculum and a way of postponing options.

Mrs Shirley Williams considers that in planning the British educational system we may not sufficiently be paying attention to the diversity of the sixth form in the modern world, in which a great many have eyes on other things than entry to a university. Not merely are there different needs of pupils to be catered for. How will teachers deal with the problems of teaching children with a variety of backgrounds when they are used to academic courses? She also raises the problem of where the science teachers are coming from and hopes there may be something to be gained from the boys or girls—particularly the girls—who stop short at a general degree at university. There is also the problem of what the sixth form population is asking for at present. Young people seem to want to make a contribution to adult life which it is not possible to ignore. That said, she considers that the pressure on the interaction between schools and universities may be eased because of the tendency for a greater proportion of people at universities to take second degrees. And here, she says, more does not mean worse—more means just more.

On the proposed treaty between the schools and the universities, many people argue that the Standing Conference on University Entrance is already equipped to do this job. It seems agreed that SCUE has considerable achievements to boast about. But Allanson points out that SCUE is only completely successful when

there is agreement. In practice, dissent among a small number of universities could block good proposals. The problem is not so much that university departments fail to delegate authority to their representatives on SCUE, but that they are not at present sufficiently well informed of new proposals coming up for a decision. And so it is considered necessary that SCUE should be more active and help to introduce new ideas for discussion in the universities.

Dr Nicol says that something different is necessary and for him there should be some sort of body or agency capable of superintending the restructuring of the sixth form in the first two years of higher education. He is impressed to see how much has been done on the schools side, where the Schools Council is empowered to deal with the whole problem of the school curriculum. It is different with the universities. People are unfamiliar with the problems. Can we go on like this? He wants to see an organization which can bridge the gap.

Jennings raises an uncomfortable question. One of the characteristics of Britain is that 10,000 people will jump to the defence of academic freedom if they consider this to be in peril. Yet people talk about reforms which are only workable if they can be adopted uniformly. For him, there should be a body which can impose its will on the universities and the other parties to the interaction between the universities and the schools. Elvin—echoed by Morrison—takes a diplomatic line. He describes how the determined pressure of opinion within universities can influence events. He thinks that

a great deal can be done by pure reason, especially if the threat of an imposed settlement is in the background.

Dr Nicol is unhappy about SCUE, because it is not fed from roots in the faculties. He would prefer a separate organization equipped to deal with problems of university entrance and problems of the first and second year courses in universities. Mrs Williams says that it is hard to see how such a system could arise without creating grave political questions concerning the relationship between the universities and the outside world. And in any case, she says, the problem may be complicated by the way in which the university teaching profession is much less homogeneous than that in the schools. Elvin has a tactful way out—let Nicol's agency deal with the transition from schools to universities, deal simply with admissions and not the broader question of the curriculum. Tester considers that if the universities do not create machinery for dealing with the problem, possibly within the Committee of Vice-Chancellors, somebody else will do it for them. But Elvin, returning to his argument that the first thing to press for is a treaty on admissions, argues that the machinery for discussion exists already—there is no reason why the vice-chancellors committee should not be asked if it will agree to put to its universities a request for an acceptance of what proposals may seem reasonable for the better regulation of the interaction between the schools and universities. It seems to be agreed that the universities could not be dealt with separately from the polytechnics and the colleges of education.

## DECLARATION

*The following statement was discussed at the final session of the conference, and may be taken as a representation of the common view rather than a form of words by each detail of which each participant is formally bound.*

It was agreed by all that a broadening of the curriculum in the sixth form is an urgent need.

For one thing, it is important to postpone for as long as possible the point at which a student at school must make decisions about what courses to follow in higher education. More important, a broad sixth form curriculum should be an educational objective in its own right. This is how best to serve the interests of students in the schools. This is how to provide a supply of educated people familiar with all aspects of the modern world. Entrants to science departments should have a better grounding in the arts. Entrants to arts departments need a core of science and mathematics.

One of the reasons why this problem has become urgent is that the size and diversity of interest of the sixth form population is growing rapidly, and sixth forms must provide recruits not merely for the universities but on an increasing scale for colleges of education, the polytechnics and for commerce and industry.

One practical benefit of a broader curriculum is that there might well result a greater supply of teachers able to teach science in the lower forms of secondary schools.

There were differences of opinion about the value and potential effect of proposals now being put forward by the Schools Council for a change in the pattern of sixth form education. The proposal is that no student should take more than two A-level examinations in any year, and that he should also follow in parallel a number of shorter courses contrasting with or supporting the A-levels and examined in some other way, together with general studies.

The schools look to this pattern not merely as a way of relieving the pressure of examinations but as a device for broadening the curriculum. There is, however, a fear that the pressure on the schools of the process of university

selection will perpetuate the present tendency to make decisions about future specialization early in the sixth form. To some, the proposals of the Schools Council would be more attractive if the character of the A-level examinations were modified.

In general, it was agreed to be desirable that students in sixth forms should be able to keep options open between the sciences. There was also wide support for the necessarily more distant objective of keeping options open between the arts and sciences.

Substantial progress towards these objectives can only be made if there are consequential changes in the pattern of university education—there must be a lengthening of university courses, a more efficient use of time at university or a decrease in the content of first degree courses. The universities may be more ready to consider the last of these possibilities because of the increasing tendency of graduates from the first degree to stay on at universities for at least one extra year.

Within a broader sixth form curriculum, mathematics needs special treatment. It is an essential part of education in engineering, the physical, biological and social sciences, and of a general education as well. There is a case for asking that a mathematics curriculum should be developed which will serve as a common core and particularly emphasize the applications of mathematics.

To make more effective the link between the schools and the universities, there is a need for some means by which university opinion on matters such as entrance can be made more univocal. The Standing Conference on University Entrance might be developed as a forum for discussion of and decision on the problems. If, however, it is to become this, some means must be found of giving it stronger roots in the university faculties and colleges.

## CAMBRIDGE CONFERENCE

## Sixth Form Studies

The following is an extract from a statement by Professor L. Rosenhead, one of the five members of the Dainton Committee soon to report.

THE material well-being of this country, as well as its intellectual strength, depends vitally on increasing the flow of young people into engineering, technology and science. Arrangements should be made for these young people to emerge from our educational machine with as good an education as can be devised, both in a general and in a specialist sense; and the graduated experts should be given satisfying and socially worth-while jobs.

Secondary education in England and Wales is more or less broadly based up to the end of the fifth form, and during that period students study eight subjects simultaneously. In the sixth forms, the number of subjects studied is drastically reduced to three (with a trivial amount of time devoted to non-examination subjects), the drastic nature of the reduction being a feature of the secondary education of only England and Wales. In all other educational systems there is some reduction in the number of subjects of study at this stage, but not as drastic as that which obtains in England and Wales. The time is now ripe for considering whether this educational practice is in keeping with the social and industrial demands of the final third of the twentieth century. In all fairness it must be said that, with the spread of the comprehensive system of education, some forward looking headmasters, acting on their own initiative, are completely transforming the pattern of sixth form education in their schools by devoting a great deal of school time to non-examination activities and studies, over and above the time devoted to three Advanced level subjects.

Students at the end of the fifth form in our secondary schools usually take O level examinations, and the available statistics on the number of passes at GCE O level, in mathematics and science subjects, have shown a steady uninterrupted increase from 1952 onwards. From 1952 to 1966 the number of passes in mathematics and science subjects has about trebled—both for boys and for girls. Expressed as a percentage of the subjects passed at O level, the proportion has increased—for boys—from about 34 to about 42 during this period; for girls the increase has been from 19 to 22 per cent. During the same period the relevant percentage in the traditional arts subjects has dropped from about 55 to about 45. The percentages for girls, though different, show the same trend.

In the sixth forms, however, the situation is completely reversed. Interest in science subjects is dropping, that in traditional arts subjects is increasing, and that in a new group, "Science-cum-Arts", is rapidly increasing. The facts are there, but the causes underlying the facts are matters to be brought into the open through discussion and investigation.

The Dainton enquiry is concerned with putting forward recommendations that will have the effect of increasing the flow of candidates into engineering, technology and science; but it is, of course, a matter for debate whether or not the flow into these fields should be increased. The Dainton report puts forward a number of recommendations, but they are largely long term in their implications.

I myself doubt whether any short term quick results can emerge, but we must try.

It is quite clear that while the output from our educational system is continuing to grow rapidly, the output of specialists in engineering, technology and science shows a quite different pattern. The annual age groups from which sixth formers are at present being drawn are appreciably smaller than those of the "bulge years" which immediately preceded them. There is now firm evidence to show that within these smaller age groups the science based activities of society are losing their hold on the imagination of our young people. The remarkable growth in the numbers enrolling for sixth form education in this country which has been achieved over the past decade seems to have occurred in those regions of study which, under present conditions, disqualify the students from entering higher education in engineering, technology and science.

Against this situation must be set the growing economic difficulties of this country, and the formidable developments in the science based industries of competitor countries such as the United States, the USSR and Japan. The new developments in those countries are associated with increased effectiveness in the exploitation of skilled manpower—whether in management, engineering or technology.

In such a developing situation, groups such as this must face the problem of whether to influence the choice and selection of individuals in relation to their studies and their future careers. The tradition of the personal freedom of the individual is deeply embedded in our educational as well as in our political traditions, and we must think very carefully before putting into train courses of action that will limit the freedom of individuals to choose their own careers. However, in educational matters, this freedom is more apparent than real. On the surface we may appear to compel our young people to decide, at the age of 16, between science based and arts based studies, but in actual fact the determining factors start to operate much earlier, probably at age 14 or even 13. This, it is now being said, is due primarily to the mechanics of school forward planning, and I am sure that this is an area that merits quick and immediate investigation. We must find out, quickly, whether it is or is not true that the processes of our educational system are compelling an increasing number of our young people to make decisions for or against science at an age when they know relatively little about it.

If we are to prepare our young people for the lives that they are going to live, it is obviously important that they must be exposed, from as early an age as possible, to talks and experiences which indicate the importance of the science based activities of society. Much has been done in this field—but much remains to be done. I am not at all convinced that the processes of formal teaching and examination are the best that can be devised if we wish to stimulate the imagination of our young people. The age of decision for young people, as between the

Table 1. NUMBER OF PUPILS ON A LEVEL COURSES IN FIRST YEAR OF SIXTH FORMS (ENGLAND AND WALES)

	January 1962	January 1963	January 1964	January 1965	January 1966
"Science" subjects only	32,708 (4.8)	35,880 (4.9)	40,091 (5.0)	38,363 (5.0)	37,429 (5.2)
"Arts" subjects only <sup>1</sup>	38,310 (5.6)	45,263 (6.2)	54,530 (6.8)	55,929 (7.2)	58,185 (8.0)
"Science cum Arts" <sup>2</sup>	7,754 (1.1)	9,430 (1.3)	12,404 (1.6)	14,275 (1.8)	15,260 (2.1)
Total	78,772 (11.6)	90,573 (12.5)	107,025 (13.4)	108,567 (14.0)	110,874 (15.3)
Estimated population of young people in England and Wales from which first year in sixth form was drawn	680,000 (100.0)	725,000 (100.0)	800,000 (100.0)	775,000 (100.0)	725,000 (100.0)

<sup>1</sup> The "arts" group has been taken to include (a) traditional arts subjects, and (b) social sciences subjects.

<sup>2</sup> At least one science subject and one arts subject.

sciences and the arts, should be postponed as far as possible.

We must bear in mind that national needs do, after all, determine opportunities for individuals, and through these opportunities they affect the pattern of the educational requirements of society. Curriculum organization in schools and universities, which has remained substantially unchanged for the past 40 to 50 years, is drastically in need of revision. The question therefore arises of whether school and university training be altered in such a way that they make provision for those who show themselves likely to become high specialists, as well as for those who show themselves suitable for the more broadly based activities of society. Further, what are the reasons underlying the growth of the "Science cum Arts" group in our schools? Is this to be encouraged or resisted by our schools? Can the universities accommodate such young people within their existing educational structure? If not, then in what way must the educational pattern be modified? If, as has been tentatively suggested, the growth of the "Science cum Arts" group is a result of the publicity given to the needs of management and management services, then are young people really preparing themselves for such careers by selecting randomly from science studies and from arts studies? Should not training for management services be planned more systematically?

There is no shadow of a doubt that the decision for or against mathematics at an early age has a strong

determining influence on the decision for or against careers in science based activities or arts based activities. At present, about two-thirds of pupils with O level passes in mathematics abandon the subject when they enter the sixth form. More people could study it to O level, and many more to A level.

Everyone seems to agree, though without demonstrable justification, that mathematics is a discipline for training in logical reasoning and thinking—and this has been emphasized so much by those who teach mathematics in schools and universities that the importance of mathematics as a means of communicating quantifiable ideas and information, and as a vital tool in the progress and practice of engineering, technology and science, has not been given adequate prominence in this country. In fact, I feel that, if the teaching of mathematics in schools and universities is to mirror the most exciting developments of the twentieth century, it must show the effects of bringing mathematics much closer to engineering, technology, science and economics than at present. The effect of presenting mathematics completely separated from the motivations that give rise to the need for mathematics would be psychologically disastrous. It would turn our independently minded young people away from the study and the use of mathematics even more than at present. It would probably attract those who wish to study mathematics as an end in itself, but would repel those who want to use mathematics to underpin studies in other fields.

## Recurrent Continental Drift of Gondwanaland

by  
J. C. BRIDEN

Department of Geology and Mineralogy,  
University of Oxford

Palaeomagnetism shows the pattern of drift of Gondwanaland for the past 600 million years. There seem to have been at least four episodes of rapid drift, with little or no drift in between.

THE principal evidence that continental drift, with or without polar wandering, has been continuous or frequent during Phanerozoic time is that the mean palaeomagnetic poles for each geological period from Europe are different, and lie in chronological order on a fairly smooth curve starting near the Equator in the Lower Palaeozoic and finishing at the present pole<sup>1,2</sup>. The same observation was made on North American rocks<sup>1-3</sup>.

The purpose of this article is to point out that the palaeomagnetic data from the southern continents appear not to conform to this pattern (Table 1, Fig. 1). Taking each continent separately, the palaeomagnetic record is too sparse and in some cases the dating of magnetization of the rocks is too uncertain to make possible a determination of the rate or the continuity of movement. Exceptions to this are that in Australia and Africa there is known to be a rapid transition within the Carboniferous<sup>5,6</sup>, and in both these continents the close grouping of Mesozoic poles indicates the absence of large-scale movement during that interval (ref. 5 and unpublished results). But if all the data from the southern continents are taken together, on any set of continental reconstructions which is compatible with the palaeomagnetic data, the poles fall in groups corresponding to time intervals which do not coincide with geological periods. Within each group there is generally no significant difference between poles, and these do not lie in chronological order. The mean poles of each group, however, do lie in chronological order. The transitions between one group and the next appear to have been accomplished quickly compared with the span of time represented by each group. It is suggested that the groups of poles represent long intervals during which little or no lateral movement of continents occurred ("quasi-static

intervals") and that the transitions between groups represent comparatively short "drift episodes".

Fig. 2 is the reconstruction for the Palaeozoic which most nearly conforms with the Palaeozoic palaeomagnetic data. There are no data from Antarctica, which is placed with the best geometrical and geological fit to southern Australia, and none from India, which is placed close to Australia so that the Mesozoic poles from the two continents coincide. The palaeomagnetic poles fall in groups, except for a few poles which refer to limited periods of geological time and which fall in transitional positions between the groups. These are:

### Group 1

Poles A1, A2, A3, B1, B2, B3, C1 and C2. These come from rocks which range in age from about 600 million years (B1) to Lower Devonian (A3). The last three were derived from limited data with no laboratory tests of stability. Differences between poles of this group may therefore arise from errors in the positions of some of the poles (themselves arising from secondary magnetization in some of the rocks from which they have been deduced) or from departures of the geomagnetic field in the Lower Palaeozoic from the geocentric dipole configuration (which is the model on which the poles were calculated). If this is so, the poles may belong to a single population. Indeed, Fisher's analysis<sup>7</sup> gives a mean pole 27° N., 4° W. relative to the present co-ordinates of Africa, with a radius of 95 per cent confidence ( $\alpha$ ) equal to 15.1°. This could indicate that there was a quasi-static interval from 600+ to about  $390 \times 10^6$  yr. The interval may have persisted into the Middle Devonian, to include pole C3, in which case the mean pole is 25° N., 1° W. ( $\alpha = 16.3^\circ$ ) as illustrated in Fig. 2.

Because of the limitations of the data, the possibility cannot be excluded of some drift within this interval. (It may be noted that Cambro-Ordovician poles  $A1$ ,  $B1$ ,  $B2$  are some  $25^\circ$  away from Silurian poles  $A2$ ,  $B3$ .) It is, however, unlikely that the drift was as great as that during any of the major drift episodes.

#### Transition between Groups 1 and 2

This is ascribed to a Middle Devonian drift episode. Precise dating of this episode depends on confirmation of

the ages assigned to the poles which delimit it. It is younger than the "Devonian" red beds ( $A3$ ) but older than the "Upper Silurian to Devonian" rocks from Australia ( $C4$ ,  $C5$ ). It is probable that pole  $C3$  records an intermediate position during the transition. The mean poles of groups 1 and 2 are  $50^\circ$  apart. If the transition took  $20 \times 10^6$  yr, this corresponds to a drift rate of about  $2.5^\circ$  per million years, which is of the same order as that suggested by Irving<sup>5</sup> for the Upper Carboniferous.

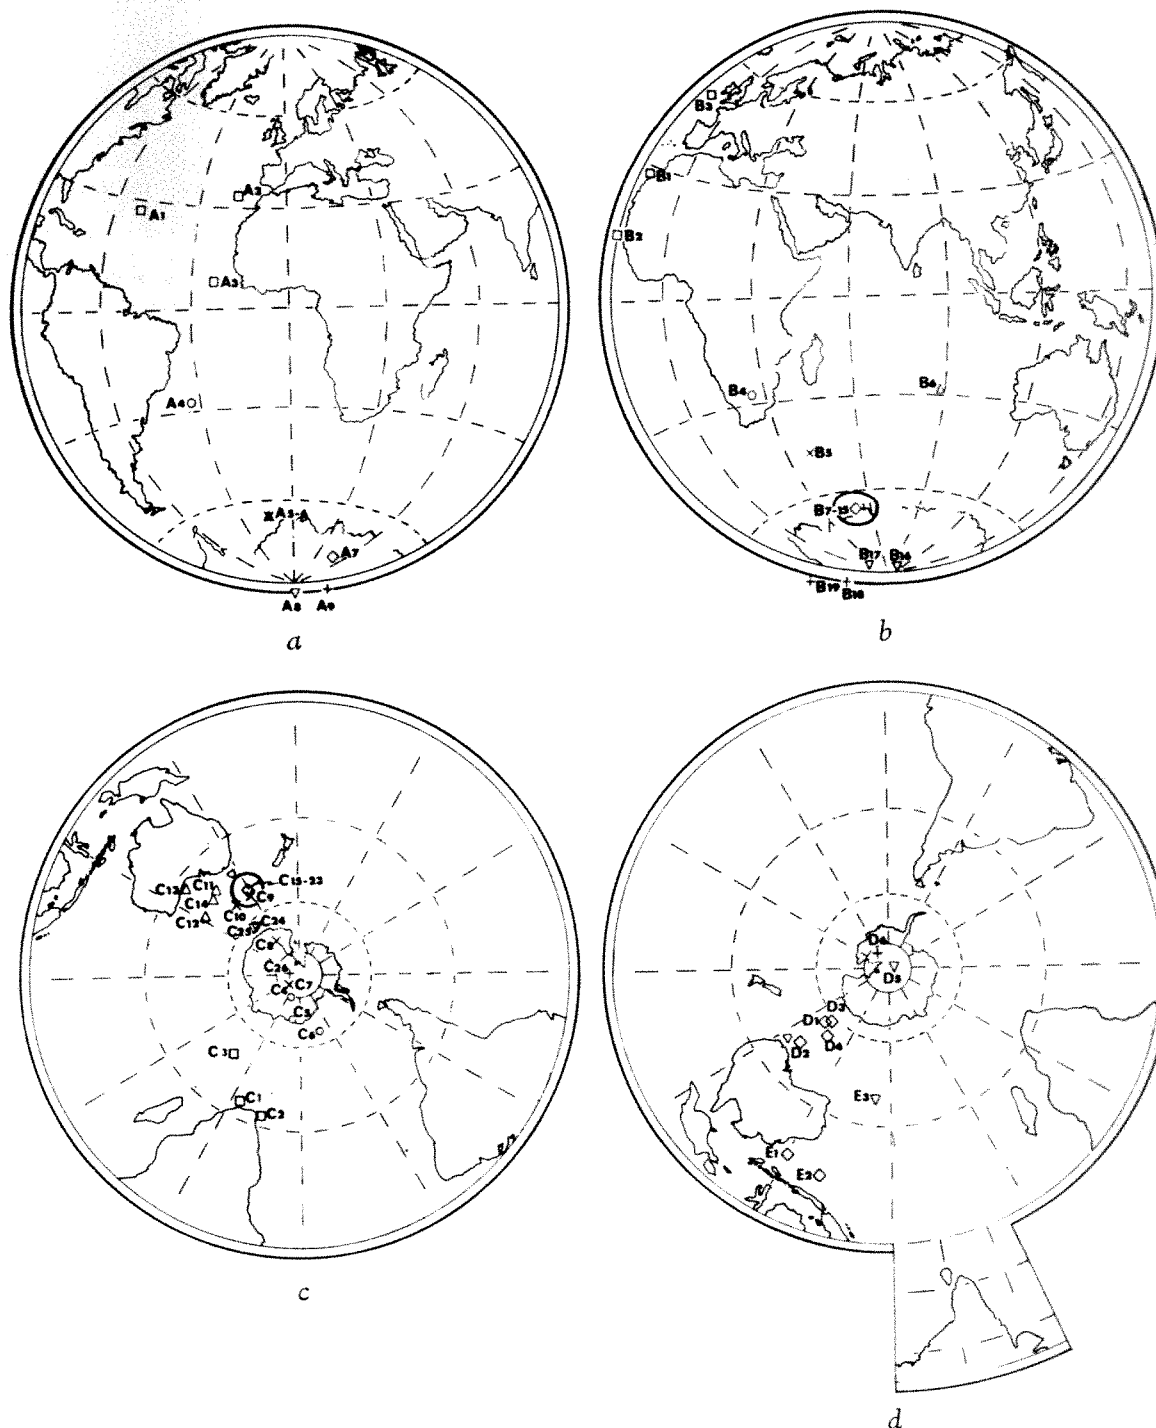

Fig. 1. Palaeomagnetic poles from Phanerozoic rocks from the Gondwana continents. (a) South America and (b) for Africa are on equal area meridional projections. (c) Australia and (d) for Antarctica and India are on polar stereographic projections. The poles are numbered in approximate chronological order within each continent and cross-referenced to Table 1. Separate symbols are used for each drift episode and quasi-static interval as follows:  $\square$ , 600+ to about  $390 \times 10^6$  yr (including pole C3);  $\circ$ , about 370 to  $320 \times 10^6$  yr;  $\times$ , Upper Carboniferous drift episode;  $\Delta$ , about 290 to  $240 \times 10^6$  yr;  $\diamond$ , about 220 to  $100 \times 10^6$  yr;  $\nabla$ , about 70 to  $20 \times 10^6$  yr;  $+$ , recent drift episode. In (b) and (c) the Mesozoic results are summarized by their mean and oval of 95 per cent confidence, but in (b) B7-15 has been plotted in the wrong longitude; it should be  $80^\circ$  E.

## Group 2

Poles A4, B4, C4, C5 and C6 range in age from "Upper Silurian to Devonian" (C4, C5) to Carboniferous (A4, B4). Their mean is at  $22\frac{1}{2}^{\circ}$  S.,  $20^{\circ}$  E. relative to the present co-ordinates of Africa and  $\alpha$  is about  $8^{\circ}$ .

This close grouping is taken to reflect a quasi-static interval from about  $370$  to  $320 \times 10^6$  yr. The interval could not have been longer than this unless the drift episodes which delimit it were very much more rapid than any previously suggested. But stratigraphic evidence indicates that the interval was not much shorter than that assigned to it here. Poles C4 and C5 are regarded as Devonian, and the Taiguati Formation (A4) and Dwyka varvoids (B4) are regarded as older than the Upper Carboniferous transition. Although four of the five poles in this group appear in Fig. 2 to lie in a line, they are not in chronological order and they are considered to form a group and not to represent slow drift.

## Transition between Groups 2 and 3

This is represented by poles A5, B5, C8 and probably C7, C9 and C10. They are all of Upper Carboniferous age and are taken to record an Upper Carboniferous drift episode. It was originally identified in New South Wales where the intermediate pole C8 was detected<sup>5</sup>, it has recently been found in Africa<sup>6</sup> and its existence is consistent with the South American data<sup>8</sup>. If the concept of Gondwanaland before the Carboniferous means anything, then the shift detected in Australia must be the same as is found elsewhere because it indicates drift of Australia towards the rest of Gondwanaland. Pole C11 may belong to the end of the transition, but it has been included in group 3 from which it is statistically indistinguishable.

## Group 3

Poles A6, B6, C11, C12, C13 and C14 are late Carboniferous and Permian. Except for A6 they are very closely grouped ( $\alpha = 5^{\circ}$ ) with a mean position relative to

Summaries of the data for South America have been provided by Creer<sup>8</sup>; for Africa by McElhinny *et al.* (unpublished); for Australia by Irving<sup>5</sup>; for India by Irving<sup>4</sup>. For chronology, see ref. 9.

the present co-ordinates of Africa at  $28^{\circ}$  S.,  $86.5^{\circ}$  E., although this statistic is dominated by the Australian results. The group is taken to reflect a quasi-static interval from about  $290$  to  $240 \times 10^6$  yr. The discrepancy of pole A6 is discussed later. It is notable that all the rocks in this group are reversely magnetized and it may be that this quasi-static interval corresponds approximately or exactly to the Kiaman magnetic interval as defined by Irving<sup>4,5</sup> during which the Earth's magnetic field retained reversed polarity for about  $50 \times 10^6$  yr.

#### Transition between Groups 3 and 4

The fact that Mesozoic poles are not well grouped on the Palaeozoic reconstruction (Fig. 2) or, to put it another way, that the Palaeozoic and Mesozoic reconstructions are different (Figs. 2 and 3) is taken to reflect another drift episode, close to the Palaeozoic-Mesozoic boundary, which is here called the Upper Permian drift episode. No intermediate pole positions have been recorded, which

may suggest that the episode was shorter than those already described. The distances involved in this episode are smaller (less than  $30^{\circ}$ ), but it is important because changes in the relative positions of the Gondwana continents are involved which did not, however, result in destroying the unity of the supercontinent.

#### Group 4

Fig. 3 is a reconstruction which satisfies all the Mesozoic palaeomagnetic data available from all five continents (but not west Antarctica). There are only Jurassic data from South America (A7), India (E1, E2) and east Antarctica (D1-4), but Australia (C15-23) and Africa (B7-15) are each represented by series of nine results spanning the time interval  $220$  to  $100 \times 10^6$  yr, another quasi-static interval ( $N = 25$ ,  $\alpha = 2.8^{\circ}$ ). This reconstruction is not unique because, unlike that in Fig. 2, it is only valid for one quasi-static interval so that relative longitude cannot be specified.

#### POSITIONS, CORRELATIONS AND DRIFT HISTORY

	Antarctica Pole	Position			India Pole	Position

								QUASI-STATIC INTERVAL (about 370 to $320 \times 10^6$ yr.)
								MIDDLE DEVONIAN DRIFT EPISODE
								QUASI-STATIC INTERVAL (600+ to about $390 \times 10^6$ yr.)

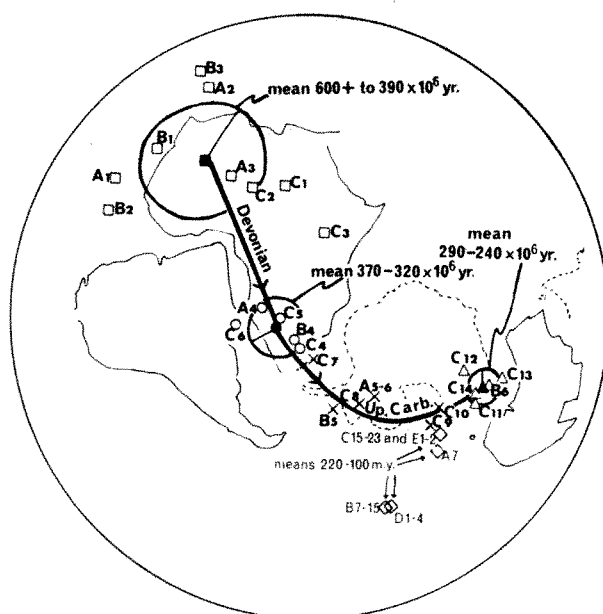

Fig. 2. Reconstruction of Gondwanaland for the Palaeozoic, together with the palaeomagnetic data. Equal area projection; notation as in Fig. 1 and Table 1. The solid symbols and thick ovals denote the mean pole and its 95 per cent confidence limits for each quasi-static interval. The thick lines are apparent polar wander curves representing movement during the drift episodes. Mean Mesozoic poles from each continent are added in lighter print.

### Transition between Groups 4 and 5

Tertiary poles are not well grouped on the Mesozoic reconstruction (Fig. 3) so that the Tertiary reconstruction is different (Fig. 4). This is a reflexion of the Upper Cretaceous drift episode—that which accounts for the major fragmentation of Gondwanaland. Separation could have begun earlier than this. Geological evidence of the influx of shallow seas along the developing fractures is likely to date from an early stage, but the divergence of polar wander curves from  $100 \times 10^6$  yr onwards (Fig. 3) shows that this was the time when large-scale lateral movements began. The limits of this episode cannot be precisely defined because of a gap in the palaeomagnetic record from about 100 to  $70 \times 10^6$  yr.

### Group 5

Fig. 4 is a reconstruction which satisfies all the poles ranging from about 70 to  $20 \times 10^6$  yr (A8, B16, B17, C24, C25, D5 and E3) with  $\alpha$  only about  $2^\circ$ . Relative longitudes are again arbitrary. Because there are only one or two results from each continent, it is not certain that the reconstruction is valid for the whole interval. South America, Africa and Antarctica may not have moved appreciably since the beginning of the Tertiary, but Australia and India could have moved more or less continuously through the past  $100 \times 10^6$  yr. On the other hand, the data are also consistent with a quasi-static interval from about 70 to  $20 \times 10^6$  yr. The older limit is uncertain because of the absence of data for the latest Cretaceous and the younger limit is vague because of another gap in the palaeomagnetic record from about 30 to  $10 \times 10^6$  yr. This interpretation is favoured, first, because it provides continuity with the pattern of stop-go drift observed in the Palaeozoic and Mesozoic and, second, because there is evidence from surveys of a change in magnetic anomaly patterns across the ocean floors corresponding to roughly  $20 \times 10^6$  yr ago<sup>10,11</sup> which may reflect the boundary between a quasi-static interval and a drift episode.

### Transition between Group 5 and the Present Pole

Poles A9, B18, B19, C26 and D6 come from rocks less than about  $10 \times 10^6$  yr old. They are close to the present pole (Fig. 1), but those from Australia and India

do not accord with the Tertiary reconstruction (Fig. 4). In conjunction with evidence for spreading of the ocean floor, which is believed to be a symptom of drift<sup>12,13</sup>, they are taken to indicate a recent drift episode during the past  $20 \times 10^6$  yr or so.

The reconstructions in Figs. 2 and 3 differ from previous ones only in detail. For example, Fig. 2 is very similar to King's<sup>14</sup> map for the Upper Carboniferous which was used by Irving<sup>5</sup> and McElhinny and Opdyke<sup>6</sup> in assessing the Australian and African data. Fig. 3 is almost identical with du Toit's<sup>15</sup> reconstruction which was found by Creer<sup>16</sup> to stand up well to comparison with palaeomagnetic data. The data presented here suggest that these reconstructions may have been valid for rather longer intervals of time than suggested by the original authors.

It remains true that an infinite set of reconstructions can be made to satisfy the palaeomagnetic data for any short period of geological time, for single palaeomagnetic studies do not permit evaluation of ancient longitude. But the reconstructions presented here are a very simple solution, satisfying the data with the minimum of drift and the minimum of relative movement. This does not of course prove that they are necessarily correct, and some modification is possible within the statistical uncertainties of the palaeomagnetic data. But, on any set of reconstructions which is generally consistent with the palaeomagnetic data and with geological evidence and geometrical constraints, the groups of poles and transitions between groups retain their integrity. Uncertainties still, of course, remain—notably the detailed history in the intervals between about  $600 \pm$  to  $390 \times 10^6$  yr and between  $100 \times 10^6$  yr and the present.

There is also to be considered an alternative interpretation of late Carboniferous and Permian data which stems from the discrepancy between the pole from some Permian red beds from South America (A6) and the other poles in group 3. There are several possible explanations. First is the possibility that the rocks involved are late Carboniferous, but this seems not to be upheld by geological evidence. The second is that pole A6 is not an accurate representation of the Permian field relative to South America, because of sampling inadequacy, partial instability of remanence or departures of the Permian field from the geocentric dipole configuration. A third possibility is that the position of pole A6 is a genuinely

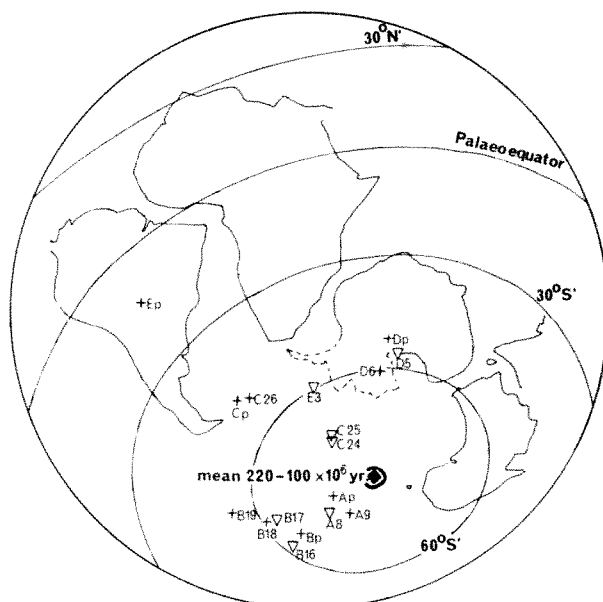

Fig. 3. A reconstruction of Gondwanaland for the quasi-static interval 220 to  $100 \times 10^6$  yr, with the palaeomagnetic poles and palaeolatitudes. Data for  $100 \times 10^6$  yr to the present are added in lighter print. Oblique equal-area projection; notation as in Figs. 1 and 2. In Figs. 3 and 4 relative longitudes are arbitrary and palaeolatitudes are denoted by primes.

Fig. 4. A reconstruction for the quasi-static interval 70 to  $20 \times 10^6$  yr with palaeomagnetic poles and palaeolatitudes. Data for  $20 \times 10^6$  yr to the present are added in lighter print. Palaeopolar equal area projection. Notation as in Figs. 1 and 2.

accurate result, in which case the drift scheme set out here requires modification.

One such modification is that A6 could be reconciled with the other group 3 poles on the reconstruction in Fig. 2, which leads to a position of South America very far south relative to Africa and further south than during the Mesozoic (Fig. 3). This is a most unlikely answer. It is easier to defend the view that Fig. 3 (with very slight modification to compromise between poles A6 and A7) is the correct reconstruction for the late Carboniferous and Permian as well as for the Mesozoic. On this scheme, the Upper Carboniferous drift episode would be complicated by relative movements between the Gondwana continents (the differences between Figs. 2 and 3) and there would be no Permian drift episode. This is in accord with Irving's<sup>5</sup> observation that there is no statistical difference between poles C9-23 (late Carboniferous to Cretaceous) from Australia, and is not incompatible with the combined pole B5+B6 originally described by Opdyke<sup>17</sup> provided all the supposedly Permian red beds from Tanzania are actually Carboniferous. This would, however, imply that the transitional poles between groups 2 and 3 (now including B6) were much more scattered than in Fig. 2. The scheme presented here is favoured by the current data, and this alternative need only be substituted if further studies confirm that pole A6 is an accurate result for the Permian of South America.

Because of uncertainties such as this about the age and duration of the drift episodes and quasi-static intervals, informal names have been used and no apology is made for using geological terminology for drift episodes and an absolute age scale for quasi-static intervals. A formal system of nomenclature cannot be erected until the course of events is known much more precisely.

It is premature to do more than point out the apparent coincidence in timing of the drift episodes with well known orogenic episodes outside Gondwanaland, and also that the drift episodes appear to occur just before times of widespread extinction of a variety of faunas. But these coincidences may well be borne in mind in the light of the recent ideas of Irving<sup>5</sup> and Hide<sup>24</sup> on possible correlations between drift episodes and frequency of reversal of the Earth's magnetic field, coupled with the possibility of correlations between field reversals and evolutionary changes for which there is both theoretical and observational evidence<sup>18-20</sup>.

## Conclusions

The burden of this argument is to present the evidence for short drift episodes interrupting long periods of little or no drift. It has been possible to distinguish three episodes of "pre-Wegenerian drift", before the dispersal of Gondwanaland. Because the bulk of the movement during these older episodes affected all of Gondwanaland equally, it is fair to ask whether they may be episodes of polar wander rather than of continental drift. The answer must depend on an assessment of Palaeozoic data from Europe and North America, for polar wander can only be demonstrated palaeomagnetically by the finding of identical differences between corresponding pairs of poles from all continents. Creer<sup>25</sup> considers that such identical differences have been found in the Palaeozoic, but this conclusion leans heavily on the interpretation of two palaeomagnetic poles from North America derived from rocks which are known to be secondarily magnetized. The conclusion is not upheld by recent results from North America<sup>21,22</sup> and, on balance, it seems that the Upper Carboniferous and Middle Devonian drift episodes did not occur with the same timing, magnitude and direction as in the southern continents. It is therefore concluded that these episodes did at least contain a component of continental drift. At this stage it is unnecessary to invoke a second mechanism (polar wander) to explain the data from Gondwanaland.

The inference from North American and European data that large-scale drift and/or polar wander has been continuous or frequent conflicts with the conclusions presented in this paper, because it is clearly unlikely that entirely different patterns were followed by the northern and southern continents. More investigation is required to test which pattern of drift has really predominated, and the first requirement is for many demagnetization studies on Palaeozoic rocks from Europe and North America. One of the few such studies<sup>23</sup> so far has given a hint that drift relative to Europe may not have been as regular as had been thought.

This work was begun at the University College of Rhodesia with the support of the US National Science Foundation, and continued at Oxford during the tenure of a travelling fellowship from the Australian National University. I am indebted to Dr M. W. McElhinny for discussion during the early stages of the work and for unpublished data, to Prof. E. Irving whose ideas on continental drift have been stimulating, to Dr R. F. King and Dr W. S. McKerrow for criticism of the manuscript, and to Miss Susan Preston for the maps.

# Mitochondrial and Cytoplasmic Polysomes from *Neurospora crassa*

by

HANS KÜNTZEL\*  
HANS NOLL

Northwestern University,  
Evanston, Illinois

Mitochondria from *Neurospora crassa* contain 73S ribosomes, which can be separated from 77S cytoplasmic ribosomes. Mitochondrial and cytoplasmic rRNA differ in sedimentation constants and base composition.

RECENTLY Stutz and Noll<sup>1</sup>, confirming earlier observations<sup>2-4</sup>, presented evidence that the chloroplasts of green plants contained polysomes consisting of 70S ribosomes in contrast to the 80S ribosomes which make up the polysomes of the surrounding cytoplasm. They also showed that chloroplast and bacterial ribosomes were indistinguishable both with respect to the sedimentation behaviour of the monomeric particle and the sedimentation coefficients (23S and 17S) of the RNA components corresponding to their 50S and 30S subunits. Observations of similar sensitivity to antibiotics<sup>5</sup> further indicated that ribosomes from bacteria and chloroplasts are very closely related. Analogous findings of a preferential inhibition of mitochondrial protein synthesis by chloramphenicol<sup>6-8</sup> and the apparent evolutionary parallelism led these authors to suggest that mitochondria, being another class of organelles containing DNA, also possess bacterial type ribosomes. We now confirm this hypothesis and present physical chemical evidence for the existence of a unique class of mitochondrial ribosomes engaged in mitochondrial protein synthesis.

In these studies, which were carried out with *Neurospora crassa*, we also examined the cytoplasmic ribosomes; the sedimentation coefficients corresponding to the monomer particles (77S) and their two RNA components ( $\alpha = 25S$ ,  $\beta = 17S$ ) were very similar to the values previously determined for cytoplasmic ribosomes of green plants<sup>1</sup>. These findings thus complement earlier observations from this laboratory and provide more evidence for the concept that there are at least three principal classes of ribosomes: organelle and bacterial, plant cytoplasmic and animal cytoplasmic ribosomes<sup>1</sup>.

Using zone velocity centrifugation in isokinetic sucrose gradients<sup>9</sup> in combination with a high resolution analysing system, we have been able to rank ribosomes from various sources in order of increasing sedimentation rate: bean chloroplasts, *Escherichia coli*, *Neurospora* mitochondria, *Neurospora* cytoplasm, bean cytoplasm, rat liver.

## Preparation of Cytoplasmic and Mitochondrial Ribosomes from *Neurospora crassa*

After preliminary experiments with rat liver cells we selected the fungus *Neurospora* as the most suitable source for the study of mitochondrial ribosomes for the following reasons: (a) under conditions of vigorous aeration these organisms grow rapidly and synthesize mitochondria at a high rate which results in the accumulation of relatively high concentrations of these organelles in the cell; (b) the cells are ruptured under relatively mild conditions and the mitochondria recovered in good yields and with high purity; (c) conditions affecting mitochondrial function can

be manipulated at will; and (d) much is known about the physiology and genetics of *Neurospora*.

Cells of *Neurospora crassa* (Em 5256, wild type strain) were grown and collected as described by Luck<sup>10</sup>. In order to isolate the mitochondria without degradation of mitochondrial ribosomes, we found it necessary to use buffer solutions with relatively high concentrations of magnesium and monovalent cations (AMT buffer: 0.1 molar  $\text{NH}_4\text{Cl}$ , 0.01 molar  $\text{MgCl}_2$ , 0.01 molar *tris*). Batches of seven Erlenmeyer flasks, each containing 200 ml. of minimal medium and an inoculum of  $1.4 \times 10^7$  conidia, were agitated in a reciprocating shaker and collected while still in the exponential growth phase after 15 h at 25° C. The cell mass (about 20 g wet weight) was collected on a Buchner funnel in the cold room, washed with two portions of 40 ml. 0.44 molar sucrose in AMT buffer, and, after mixing with 10 g of acid-washed sea sand, ground to a paste while gradually adding 30 ml. of sucrose-AMT. The extract was centrifuged for 10 min at 500*g* in a swinging bucket centrifuge and the pellet extracted with another portion of 25 ml. sucrose-AMT. The combined supernatants were then centrifuged for 20 min at 80 per cent line voltage (26,000*g*) in a Servall SS-1 centrifuge. The postmitochondrial supernatant was saved for the isolation of cytoplasmic ribosomes, the crude mitochondrial pellet (about 30 mg total protein) suspended in sucrose-AMT to a concentration of 10 mg/ml. and portions of 2 ml. layered over gradients consisting of seven 3-ml. steps of 2.1, 1.95, 1.8, 1.65, 1.5, 1.35, 1.2 molar and a 12 ml. top layer of 0.9 molar sucrose (made up in AMT) in 35 ml. swinging bucket tubes of a rotor SB-110 (International Equipment Company). After centrifugation for 60 min at 25,000 r.p.m. and 3° C, the yellowish mitochondrial band at the interphase between the 1.5 and 1.65 molar sucrose layers was removed and either used immediately for preparing ribosomes or stored at -20° C. The yield was about 25 mg protein from each batch of seven flasks.

To prepare ribosomes, the mitochondrial fraction was diluted with AMT to make it 0.44 molar with respect to sucrose and spun down by centrifugation. The mitochondrial pellet was taken up in AMT (1.0 ml./5 mg of protein) and lysed by adding 0.05 ml. of a 20 per cent solution of 'Triton X-100'/ml. of suspension and mixing with a hypodermic syringe. Treatment with 'Triton X-100' does not lyse present bacteria<sup>11</sup>. The clear lysate was either subjected directly to sedimentation analysis or used to isolate purified ribosomes by layering portions of 7 ml. over 3 ml. of 0.9 molar sucrose-AMT and centrifuging for 14 h at 40,000 r.p.m. and 3° C in an I.E.C. or Spinco angle head rotor. The translucent yellow pellets were rinsed quickly with AMT to remove a thin layer of a greenish-yellow precipitate from the surface and resuspended in

\* Present address: Max-Planck-Institute for Medical Research, 34 Göttingen, Germany.

AMT. After a clarifying spin the solution (about 1 mg RNA/ml.) was stored at  $-60^{\circ}\text{C}$ . The yield was about  $30\text{ }\mu\text{g}$  RNA/mg mitochondrial protein.

To isolate the cytoplasmic ribosomes, the postmitochondrial supernatant was made 0.5 per cent with respect to 'Triton X-100' and centrifuged to remove insoluble material as described by Stutz and Noll<sup>1</sup>. The supernatant was layered over 2 ml. of 1.0 molar sucrose-AMT, centrifuged for 2 h at 40,000 r.p.m. and  $3^{\circ}\text{C}$  and the resuspended pellets (5 mg/ml.) stored at  $-60^{\circ}\text{C}$ .

### Resolution of 73S Mitochondrial and 77S Cytoplasmic Ribosomes by Zone Velocity Sedimentation

To determine whether cytoplasmic and mitochondrial ribosomes are different, we examined the sedimentation behaviour of ribosome preparations from the two sources in sucrose gradients. Fig. 1 shows strip chart recordings of sedimentation patterns characteristic of cytoplasmic polysomes (A), mitochondrial lysates (B) and a mixture of the two preparations (C). The two preparations are strikingly different: the pattern of the cytoplasmic polysomes exhibits a strong monomer peak corresponding to 77S which is followed by clearly resolved polysome peaks ranging from dimer to hexamer, while in the mitochondrial lysate the polysome region is not resolved and the strongest peak sediments somewhat more slowly, corresponding to an *S*-value of 73. In addition, two prominent slower components corresponding to 50S and about 40S are always present in the mitochondrial lysate. The difference in sedimentation rate between the cytoplasmic and mitochondrial monomer species, although slight, is firmly established by the fact that the two components have been clearly resolved during co-sedimentation in the same tube (C). Indeed, the sedimentation pattern obtained with the mixture corresponds exactly to the summation curve produced by superimposing the tracings of the two components. Equally, separations, not shown here, were obtained when purified ribosomes from mitochondria (Fig. 2) were centrifuged after they had been mixed with cytoplasmic ribosomes. The difference between the sedimentation rate of the two ribosomes is only 5 per cent.

To evaluate the significance of the unexpected similarity in sedimentation rates of cytoplasmic and mitochondrial ribosomes from *Neurospora*, a more precise characterization of their sedimentation rates was carried out by comparing them under standardized conditions with representatives from other ribosome classes. In these experiments *E. coli* ribosomes with an assumed sedi-

Fig. 1. Sedimentation pattern of a mitochondrial lysate and of cytoplasmic ribosomes from *Neurospora*. Cytoplasmic ribosomes and freshly prepared mitochondrial lysates were layered on 12 ml. convex sucrose gradients made up in AMT and centrifuged for 2 h at 41,000 r.p.m.,  $3^{\circ}\text{C}$ , in the rotor (SB-283, B-60 centrifuge, International Equipment Company). A, Cytoplasmic ribosomes (0.68  $A_{260}$  units equivalent to  $34\text{ }\mu\text{g}$  RNA in  $5\text{ }\mu\text{l}$ . AMT). B, Mitochondrial lysate (5 mg protein in 0.5 ml. AMT, containing 1 per cent 'Triton-X-100'). C, Mixture of A and B.

Fig. 2. Sedimentation pattern of isolated mitochondrial ribosomes. Freshly prepared mitochondrial ribosomes (1.8 mg RNA dissolved in 0.2 ml. AMT) were layered on a 12 ml. convex sucrose-AMT gradient and centrifuged for 2 h at 40,000 r.p.m.,  $3^{\circ}\text{C}$ . The ordinate corresponds to 0.625  $A_{260}$  units.

mentation coefficient of 70S served as calibrating standard. The samples were mixed in the combinations shown in Table 1 and, for optimal resolution, centrifuged in an isokinetic gradient<sup>9</sup> to a position about one quarter above the bottom of the long 12 ml. tubes of the I.E.C. SB-283 rotor. The mobilities of the 70/50/30S *E. coli* calibrating standards indicate that the particles sedimented at a perfectly constant rate. To the results in Table 1 we have added the previously published values for chloroplast ribosomes from beans<sup>1</sup>. Of particular interest is the finding that mitochondrial ribosomes from *Neurospora* have a markedly higher *S* value (73.2) than *E. coli* ribosomes and sediment at a rate intermediate between that of *E. coli* (70S) and *Neurospora* cytoplasmic ribosomes (77S). By contrast, the sedimentation rate of chloroplast ribosomes (67S) is lower than that of *E. coli* ribosomes by about the same amount.

We estimate that the relative *S*-values which establish the ranking order in Table 1 are accurate within about  $\pm 0.3$  units. Thus we believe that the figures are significant which indicate that the cytoplasmic ribosomes from *Neurospora* sediment somewhat slower and those from liver somewhat faster than bean cytoplasmic ribosomes. It should also be noted that the values obtained here by constant velocity sedimentation are in excellent agreement with published data determined with the analytical ultracentrifuge.

5	179	186	192	207
6			215	230

The conclusions that the mitochondrial ribosomes in *Neurospora* are different from those in the cytoplasm is further supported by an examination of the polysomes from the two cell compartments. The sedimentation pattern of mitochondrial lysates often exhibits a number of polysome peaks visible as distinct shoulders above the leading edge of the predominant monomer peak (Fig. 6). It is evident that these peaks are more closely spaced than the polysome peaks in the sedimentation pattern of the cytoplasmic preparation (Fig. 1A). Thus, it is clear from the *S*-values compiled in Table 2 that the difference observed between the two types of monomer ribosomes is reflected and magnified in the *S*-values of the corresponding polysome series. For comparison we have included the analogous data for *E. coli* and rat liver cytoplasmic ribosomes.

### Subunits of Mitochondrial and Cytoplasmic Ribosomes

Sedimentation diagrams of the mitochondrial lysate always exhibit two closely spaced peaks in the 35 to 50S region (Fig. 1B). In preparations of purified mitochondrial ribosomes an additional, more rapidly sedimenting component is revealed (Fig. 2). The positions of the three subunit peaks in Fig. 2 correspond to 57-58, 51 and 35-36S. In a large number of patterns examined the 51S peak was always the strongest, whereas the intensity of the other two peaks relative to this principal peak varied considerably. We also noted that the increase of the 51S peak, which was particularly pronounced after thawing frozen samples of purified mitochondrial ribosomes, regularly occurred at the expense of the 73S monomeric ribosome unit. This indicates that the 51S peak corresponds to the large subunit of mitochondrial ribosomes. Because the conditions responsible for the variable amount of the 51S component evidently failed to affect the amounts of other subunit peaks, we conclude that these minor peaks are of a different origin, most likely the subunits of cytoplasmic ribosomes present in variable proportions as contaminants. In support of this interpretation it may be pointed out that the sedimentation constants of the minor peaks (57/35S) correspond closely to the values expected for the subunits of the 77S cytoplasmic ribosomes. The 35S peak was always much smaller, in relation to the larger subunits, however, than expected on the basis of an equimolar ratio. The failure to recover an equivalent proportion of the smaller subunits is a general observation which we attribute to the tendency of these particles to remain bound to larger aggregates because of their strong interaction with messenger RNA. The broad nature of the 35S peak further suggests that it arises from a mixture of the two smaller subunits (expected to sediment at about 36 and 30S) derived from both the cytoplasmic and mitochondrial ribosomes.

### Characterization of RNA from Mitochondrial and Cytoplasmic Ribosomes

Surveys carried out in several laboratories suggest that the ribosomes from a wide spectrum of organisms may be grouped into three broad classes (*A*, *B*, and *C*, Table 3) based on the size or derivative properties (sedimentation rate, electrophoretic mobility) of their ribosomal RNA. These relationships are summarized in Table 3 which compares the relative sedimentation rates of representatives of the three classes in the presence of either magnesium or sodium ions. To facilitate comparison we have

normalized all measurements using as calibrating standard the small component of *E. coli* (*C* $\beta$ ) and assigning it a value of 16S. It can be seen that regardless of ionic conditions members of the three classes differ most significantly among each other in the sedimentation rate of the large component relative to the *E. coli* 16S component. By adopting this reference system, the three classes may be characterized by the following generic sedimentation values: *A* = 30/18, *B* = 25/17, and *C* = 22/16.

Table 3. RELATIVE SEDIMENTATION RATES OF RIBOSOMAL RNA FROM THREE CLASSES OF RIBOSOMES IN THE PRESENCE OF Mg<sup>++</sup> OR Na<sup>+</sup>

rRNA components:		Relative <i>S</i> values				Ratio $\alpha/\beta$	
Class of ribosomes	Source	$\alpha$	$\beta$	$\alpha$	$\beta$	Mg <sup>++</sup>	Na <sup>+</sup>
		0.001 molar Mg <sup>++</sup>	0.01 molar Na <sup>+</sup>	0.01 molar Na <sup>+</sup>	0.01 molar Na <sup>+</sup>		
<i>A</i>	Rat liver cytoplasm	30.4	18.9	29.5	17.8	1.61	1.66
<i>B</i>	Bean cytoplasm	26.5	16.0	25.9	17.0	1.65	1.52
	<i>Neurospora</i> cytoplasm	25.8	16.5	25.0	17.4	1.56	1.44
<i>C</i>	<i>E. coli</i>	22.6	16.0	21.2	16.0	1.41	1.31
	Mitochondria ( <i>Neurospora</i> )	23.0	16.2	20.5	16.4	1.42	1.29
	Chloroplasts	22.6	15.9	20.8	15.7	1.42	1.33

The preparations were centrifuged in the I.E.C. SB-283 rotor for 12 h at 35,000 r.p.m. and 3° C. Relative *S* values were determined from the peak positions on the strip chart recordings with the aid of an empirical calibration curve. All values were normalized by arbitrarily setting *E. coli* rRNA  $\beta$  = 16.0. Following the convention proposed previously, we designate the larger rRNA component with the letter  $\alpha$ , the smaller with  $\beta$ .

In Table 4 we have listed the number and *S* values of clearly separated peaks observed in the sedimentation diagrams of mixtures containing ribosomes from two different classes in the three possible combinations. The analyses were carried out in the presence and absence of magnesium ions. It is interesting to note that the Na<sup>+</sup> system is capable of resolving the larger but none of the smaller components of all possible pairs (unpublished results of Stutz and Rawson). On the other hand, in some cases the system containing magnesium ions permits the separation of all four components. In other cases, exemplified by all mixtures containing type *B* + *C* ribosomes, this system fails to separate any of the components.

The results obtained with RNA from cytoplasmic and mitochondrial ribosomes (Tables 3 and 4 and Figs. 3-5) clearly show that the cytoplasmic RNA of *Neurospora* belongs to the 25/17S type (class *B*), whereas the mitochondrial RNA is most closely related to bacterial RNA (class *C*). In particular it is evident from Fig. 3 that in the presence of magnesium ions cytoplasmic RNA from *Neurospora* can be separated from the RNA of rat liver but not from that of bean cytoplasm. Fig. 4 shows that *Neurospora* cytoplasmic RNA sediments more rapidly than either *E. coli* RNA or mitochondrial RNA, although it cannot be separated when mixed with *E. coli* RNA. The sedimentation diagram of the mixture containing RNA from *E. coli* and *Neurospora* cytoplasm (Fig. 4D), however, exhibits a noticeable broadening of the two peaks, and the peaks of the mixture are located between the positions of the individual components, indicating

Table 4. RESOLUTION OF COMPONENTS IN rRNA MIXTURES PREPARED FROM TWO DIFFERENT RIBOSOME CLASSES

rRNA components: Mixture	Source	Relative <i>S</i> values		Ratio $\alpha/\beta$	
		$\alpha$	$\beta$	$\alpha$	$\beta$
		0.001 molar Mg <sup>++</sup>	0.01 molar Na <sup>+</sup>		
<i>A</i> + <i>B</i>	Rat liver + bean	4 peaks: 31.4 18.6 26.6 16.0	3 peaks: 29.5 17.3		
		3 peaks: ( $\beta$ -peaks partially resolved)			
	Rat liver + <i>Neurospora</i>	31.1 18.4 26.1	29.5 17.5 24.8		
		3 peaks:	3 peaks:		
<i>A</i> + <i>C</i>	Rat liver + <i>E. coli</i>	29.0 16.2 22.9	29.0 16.9 20.9		
		2 broad peaks:	3 peaks:		
<i>B</i> + <i>C</i>	Bean cytoplasm + <i>E. coli</i>	24.3 16.3	24.9 16.5 21.0		
	<i>Neurospora</i> cytoplasm + mitochondria	24.2 16.2	25.0 17.0 20.5		

that the two species interact reversibly during sedimentation. The fast moving peak in the mixture can be shown to result from incomplete disruption of the *E. coli* 50S subunit by the detergent sodium dodecylsulphate (unpublished results of Stutz and Rawson). Mitochondrial and *E. coli* RNA, on the other hand, sediment almost identically (Fig. 4B and C), except that the larger component of the mitochondrial preparation is slightly faster as expected from the somewhat larger *S* value of the parent ribosome. The nature of the minor fast component has not been elucidated. A comparison of the two types of RNA from *Neurospora* in the absence of magnesium ions (Fig. 5) further corroborates their distinct nature; the larger components of mitochondrial and cytoplasmic RNA are resolved as expected from the analogous behaviour previously reported for cytoplasmic and chloroplast RNA from green plants. It should be stressed that even our best RNA preparations from either chloroplasts or mitochondria have suffered at least partial degradation because of the ubiquitous presence of nucleases in plant material. This degradation is always more pronounced in the absence of magnesium ions which seem to protect the molecules by keeping them in a more compact conformation.

#### Base Composition of Mitochondrial and Cytoplasmic rRNA

In an attempt to confirm by chemical method the differences between mitochondrial and cytoplasmic ribo-

Fig. 3. Sedimentation pattern of rRNA from *Neurospora*, bean and rat liver cytoplasmic ribosomes. Ribosomes equivalent to 0.9 mg RNA were dissolved in 1 ml. of AMT, and a 10 per cent solution of SDS was added to a final concentration of 2 per cent. The mixture was incubated for 10 sec at 37° C. After chilling, 0.2 ml. of the mixture were layered immediately on 12 ml. convex sucrose gradients made up in 0.002 molar MgCl<sub>2</sub>, 0.001 molar tris-HCl, pH 7.5 and centrifuged for 13.5 h at 35,000 r.p.m., 3° C. The ordinate corresponds to 1.25 A<sub>280</sub> units. A, *Neurospora* 25/17S (0.2 ml.). B, *Neurospora* and bean 25/17S (each 0.1 ml.). C, *Neurospora* and rat liver 25/17S, 29/18S (each 0.1 ml.). D, Rat liver 29/18S (0.2 ml.).

Fig. 4. Sedimentation pattern of cytoplasmic and mitochondrial rRNA from *Neurospora* and of *E. coli* rRNA. Ribosomes were treated with SDS as described in Fig. 3. 12 ml. convex sucrose gradients made up in 0.002 molar MgCl<sub>2</sub>, 0.001 molar tris-HCl, pH 7.5 were centrifuged for 12 h at 35,000 r.p.m., 3° C. The ordinate corresponds to 1.25 A<sub>280</sub> units. A, *Neurospora* cytoplasmic rRNA 25/17S (0.2 ml.). B, *Neurospora* mitochondrial rRNA 23/16S (0.1 ml.). C, *E. coli* 22/16S (0.2 ml.). D, A (0.1 ml.) + C (0.1 ml.).

somes established by the physico-chemical analyses, we examined the nucleotide composition of the ribosomal RNA from the two sources.

Suspensions of purified cytoplasmic or mitochondrial ribosomes labelled with phosphorus-32 were diluted to contain no more than 0.9 mg RNA/ml. The ribosomes were then disrupted in the presence of 2 per cent sodium dodecylsulphate (SDS)<sup>1</sup>. The lysate was centrifuged through a convex exponential sucrose gradient in the I.E.C. rotor SB-283 for 12 h at 35,000 r.p.m. and 3° C. The gradient fractions containing the two rRNA peaks were collected and pooled. The RNA was isolated, hydrolysed and analysed by high voltage paper electrophoresis as described in the legend to Table 5. The results reveal a striking difference in the nucleotide composition of the two RNA species: cytoplasmic RNA has a much higher GC-content ( $G + C/A + U = 1.02$ ) than mitochondrial RNA ( $G + C/A + U = 0.66$ ). Of particular interest is the unusually low proportion of CMP. Another characteristic feature of mitochondrial RNA is the relatively high proportion (5 per cent) of unidentified component with a mobility between that of AMP and GMP. An unknown product in hydrolysates of chloroplast rRNA from *Euglena* has been previously reported by Brawerman and Chargaff<sup>12</sup>.

#### Protein Synthesis by Mitochondrial Polysomes

We have tested the ability of intact mitochondria to incorporate amino-acids into protein. Purified mitochondria were incubated at 37° C with <sup>14</sup>C-leucine under the conditions described by Wheeldon and Lehninger<sup>8</sup> and after intervals ranging from 5 to 40 min samples of

Fig. 5. Sedimentation pattern of cytoplasmic and mitochondrial rRNA from *Neurospora*. Ribosomes were treated with SDS as described in Fig. 3. 12 ml. convex sucrose gradients containing 0.01 molar NaCl, 0.005 molar *tris*-HCl, pH 7.5 were centrifuged for 12 h at 35,000 r.p.m., 3° C. The ordinate corresponds to 1.25  $A_{260}$  units. A, Cytoplasmic rRNA (0.2 ml.). B, Mitochondrial rRNA (0.2 ml.). C, Mixture of A+B.

0.5 ml. were withdrawn and diluted with ice-cold AMT-buffer. The mitochondrial pellets obtained after centrifugation were lysed with 'Triton X-100' and subjected to zone-velocity centrifugation in sucrose gradients. The contents of the tubes were analysed for absorbancy by automatic spectrophotometric scanning of the effluent and the fractions assayed for acid-insoluble radioactivity<sup>13</sup>. Fig. 6 shows the distribution of radioactivity and ribosomes observed after 5 and 20 min; the radioactivity is mainly associated with the polysome region, a smaller fraction with the supernatant. The proportion of acid-insoluble radioactivity in the supernatant fraction increases with time; some of the nascent chains originally associated

with polysomes are completed and released. Because there is little if any nascent protein associated with the monomer peak, the rather large proportion of monomers does not seem to result from degradation of polysomes by RNase action, but is more likely to be attributable to poor physiological conditions which usually have been found to cause polysome breakdown by a preferential inhibition of chain initiation. This explanation is supported by the observation that the mitochondria begin to lyse after the first 20 min of incubation.

Similarly, the low incorporation of radioactive amino-acids is probably caused by a large internal amino-acid pool and by unfavourable conditions for the transport of amino-acids through the mitochondrial membrane.

Fig. 6. Incorporation of  $^{14}\text{C}$ -leucine into mitochondrial protein. The incubation mixture contained (in  $\mu\text{moles/ml.}$ ): sucrose (440), KCl (100),  $\text{MgCl}_2$  (10),  $\text{KH}_2\text{PO}_4$  (10), proline (5), phosphoenolpyruvate, cyclohexylammonium salt (5), ATP (2), *tris*-HCl, pH 7.5 (33), amino-acid mixture minus leucine (0.1 each),  $^{14}\text{C}$ -leucine, specific activity 200 mc./mmole (3  $\mu\text{c.}/\text{ml.}$ ), pyruvate kinase (10  $\mu\text{g.}/\text{ml.}$ ) and purified mitochondria (10 mg protein/ml.). Incubation was at 37° C. 0.5 ml. aliquots were taken out as specified, diluted with 5 ml. ice cold 0.44 molar sucrose-AMT and centrifuged for 15 min at 85 per cent line voltage in the Servall SS-1. The pellets were lysed with 0.5 ml. AMT containing 1 per cent 'Triton X-100' and layered on 12 ml. convex sucrose gradients containing AMT. After centrifugation for 2 h at 40,000 r.p.m., 3° C. the gradients were collected in 1.2 ml. fractions. The fractions were assayed for radioactive protein as described previously<sup>12,13</sup>.

Table 5. BASE COMPOSITION OF CYTOPLASMIC AND MITOCHONDRIAL RIBOSOMAL RNA FROM *Neurospora* (In moles per cent)

	AMP	UMP	GMP	CMP	Unidentified
Cytoplasmic RNA: 25.8+17.8	24.1±0.5	24.3±0.8	28.1±0.2	21.1±0.3	2.3±0.6
Mitochondrial RNA: 21.8+16.8	27.2±0.5	29.8±0.7	22.9±0.5	14.8±0.8	5.7±0.1

Cells labelled with phosphorus-32 were obtained by adding 1.2 mc. sodium phosphate- $^{32}\text{P}$  (Abbott Laboratories) to 200 ml. minimal medium. The mitochondria were isolated and mitochondrial ribosomes were treated with SDS as described under Fig. 3 and layered over 12 ml. gradients (sucrose-AMT). After centrifugation for 12 h at 35,000 r.p.m., 3° C. the fractions containing the two rRNA peaks were collected and pooled. To precipitate the RNA 0.1 vol. of 1 molar potassium acetate pH 5 and 3 vol. of 95 per cent ethanol were added. The precipitate was dried, dissolved in 0.1 ml. 0.3 molar KOH/0.4 mg RNA and incubated at 30° C for 12 h. The hydrolysate was neutralized with 0.3 molar  $\text{HClO}_4$ , the potassium perchlorate was removed by centrifugation and 10  $\mu\text{l.}$  of the supernatant containing about 8,000 c.p.m. were applied on Whatman 1 MM paper and subjected to electrophoresis on a Savant flat plate system at 2,800 V, 30 mamp for 3.5 h. The electrophoresis buffer (pH 3.5) contained 0.6 molar acetic acid, 0.01 molar EDTA and 34 ml. pyridine/l. The dried electropherogram was cut in 6 mm strips and counted in a Packard liquid scintillation counter.

The significance of incorporation data obtained with mitochondria under non-sterile conditions has been questioned because of the possibility that bacterial contaminations might be the principal source of the incorporation activity. We therefore wish to point out that under our assay conditions the presence of bacteria would not affect the results, for they fail to lyse in the presence of 'Triton X-100' (ref. 11).

## Discussion

While it has been firmly established that mitochondria are endowed with their own DNA (ref. 14), the question whether these organelles also contain ribosomes and, if so, whether they are distinct from cytoplasmic ribosomes has remained an enigma. Several recent observations, however, have encouraged the search for specific mitochondrial ribosomes. Thus isolated mitochondria have been reported to be capable of incorporating amino-acids into their structural protein<sup>15</sup>. Other observations suggested that mitochondrial protein synthesis was suscep-

tible to inhibitors that fail to affect cytoplasmic protein synthesis<sup>6-8,16</sup>. Particularly persuasive are observations by Kirk and Juniper<sup>17</sup>, who found that streptomycin inhibited the development of both chloroplasts and mitochondria. The observations with chloroplasts seemed to find their explanation in the demonstration by Stutz and Noll<sup>1</sup> that these organelles contain bacterial type ribosomes, who also pointed out that chloroplast function and development seem to be affected by all those antibiotics that specifically inhibit protein synthesis on bacterial ribosomes. Most recently the isolation of a tRNA and aminoacyl-synthetase specific for mitochondria has been reported<sup>18</sup>.

The isolation of a 55S ribosome particle from rat liver mitochondria believed to be the active unit in mitochondrial protein synthesis was recently described<sup>19,20</sup>. No evidence was, however, given to rule out that it was not a subunit from a mitochondrial ribosome.

In this report we described the isolation of a new type of ribosome from *Neurospora* that meets some rigorous tests to qualify as the structural unit responsible for mitochondrial protein synthesis: (1) it occurs only in mitochondria; (2) it can be distinguished from cytoplasmic ribosomes by sedimentation analysis of either the intact particles or the corresponding RNA component and chemically by its unique base composition; (3) it exhibits the characteristic subunit structure and resembles bacterial ribosomes; and (4) it forms polysomes engaged in mitochondrial protein synthesis.

Although the mitochondrial ribosome clearly belongs to the bacterial class, we were surprised to find that, having an *S*-value of 73, it was distinctly larger than both chloroplast (67S) and most of the bacterial ribosomes (70S) (ref. 21). As the cytoplasmic ribosomes of *Neurospora* are somewhat smaller than expected, the actual difference of barely 4S makes it difficult to resolve a mixture of the two species by zone velocity centrifugation. The separation achieved here, though clear-cut and obtained reproducibly with specialized high resolution equipment, probably comes very close to the limit of the resolving power of the techniques used.

An intriguing aspect of our comparative sedimentation studies with ribosomes from widely differing sources is the

apparent increase in size accompanying evolution to higher forms. If we accept this as a rule to map the course of evolution, it is interesting to note that within the class of bacterial type ribosomes the chloroplast ribosomes rank at the very bottom together with the 66S ribosomes of the photosynthetic bacteria (*Rhodospirillum rubrum*)<sup>21</sup>, whereas the mitochondrial ribosomes rank at the top with 73S *Bacillus licheniformis*. It is tempting to speculate that endosymbiotic forms are relics of the distant past still reflecting the ancestors of the two organelles in the process of integration to form a eucaryotic cell. By the same token, the low position of the chloroplast ribosome could be taken as confirmation of the obvious postulate that photosynthesis must have its origin at the very threshold of life.

We thank Dr E. Stutz for making available calibration curves and unpublished results, and Dr M. Jost for his advice. This work was supported by grants from the US National Institutes of Health and the American Cancer Society.

## Molecular and Genetic Aspects of Human Blood-group Le<sup>b</sup> Specificity

by

ANNE M. S. MARR  
A. S. R. DONALD  
WINIFRED M. WATKINS  
W. T. J. MORGAN

The Lister Institute of Preventive Medicine,  
London, S.W.1

Chemical characterization of Le<sup>b</sup>-active fragments isolated from alkaline degradation products of human blood-group HLe<sup>b</sup> substance supports the idea that Le<sup>b</sup> specificity results from the action of two genes. These are *H* and *Le*, and they belong to independent blood-group gene systems, *Hh* and *Lele*.

THE chemical nature of the serologically reactive structures responsible for the A, B, H and Le<sup>a</sup> specificity of the blood-group active glycoproteins in human secretions and tissue extracts has been established and the inter-relationships of the different specificities are now largely understood<sup>1-3</sup>. The specific determinants were identified as carbohydrate structures in which the immunodominant sugar is a non-reducing residue present at the end of, or as a branching unit on, the carbohydrate chains. The overall structure of the glycoprotein molecules is not yet completely elucidated, but there is no doubt that in each

macromolecule there are many carbohydrate chains ending in blood-group active groupings. The available evidence also supports the view that A, B, H and Le<sup>a</sup> specificities arise from structures superimposed on a common precursor type of glycoprotein and that, according to the genetic make-up of the donor from whom the blood-group substance is obtained, some or all of these specificities occur on individual macromolecules.

The structures responsible for specificity were identified by the inhibition of specific haemagglutination<sup>4,5</sup> and precipitation<sup>6,7</sup> by sugar derivatives of known structure,

by the sequential degradation of the carbohydrate chains by specific enzymes<sup>8</sup> and by chemical identification of serologically active fragments arising from the partial acid hydrolysis<sup>9-13</sup> or alkaline degradation<sup>14-19</sup> of the group specific substances. Partial degradation products of A, B and H substances each yielded two different kinds of serologically active trisaccharide and on the basis of this finding it was proposed that in the precursor glycoprotein two types of carbohydrate chain-endings form the backbone of the serologically active structures<sup>20</sup>: type 1 chain-ending  $\beta$ -Gal-(1 $\rightarrow$ 3)- $\beta$ -GNac . . . and type 2 chain-ending  $\beta$ -Gal-(1 $\rightarrow$ 4)- $\beta$ -GNac . . . (Gal, D-galactopyranose; GNac, N-acetyl-D-glucosaminopyranose).

The two H-active trisaccharides<sup>16</sup> correspond to the two chain-endings with  $\alpha$ -L-fucosyl residues joined in (1 $\rightarrow$ 2) linkage to the non-reducing galactose end residues. In contrast only one active trisaccharide was obtained from Le<sup>a</sup> substance. This trisaccharide arises from the type 1 chain by the addition of an  $\alpha$ -L-fucosyl residue to the carbon-4 position in N-acetylglucosamine. In the type 2 chain the carbon-4 position of the subterminal N-acetylglucosamine is substituted by the terminal galactose, so that this type of chain cannot give rise to an Le<sup>a</sup>-active structure.

A fifth blood-group specificity associated with the secreted blood-group active glycoproteins is the Le<sup>b</sup> character<sup>21</sup>. Inhibition tests with oligosaccharides of known structure indicated the nature of the Le<sup>b</sup> determinant<sup>22,5</sup> but until now no direct chemical evidence in support of this structure was forthcoming. Of many carbohydrates tested only two, lacto-N-difucohexaose I (1)<sup>23</sup>,

and lacto-difucotetraose<sup>24</sup> inhibited in the Le<sup>b</sup> system, and it was therefore proposed<sup>22,5</sup> that the Le<sup>b</sup> determinant was constituted by two  $\alpha$ -L-fucosyl units joined by glycosidic linkages to each of two adjacent sugars, as in the tetrasaccharide moiety at the non-reducing end of lacto-N-difucohexaose I.

In this communication the isolation of two Le<sup>b</sup>-active oligosaccharides from a human HLe<sup>b</sup> substance is described and the significance of the structure of the Le<sup>b</sup> determinant is discussed in terms of the genetic control of its formation.

### Isolation and Characterization of Le<sup>b</sup>-active Oligosaccharides

A preparation of HLe<sup>b</sup> substance (No. 534, 10.2 g containing fucose 13.4, galactose 22.6, N-acetylhexosamine 25.7, amino-acids 25 per cent; molar ratio N-acetyl-galactosamine to N-acetylglucosamine 1:2.9) isolated from a single specimen of ovarian cyst fluid from a group O "secretor" person was dissolved in 850 ml. of a water soluble non-diffusible poly(vinylbenzyltriethyl) ammonium hydroxide resin<sup>25</sup> in its carbonate form (0.05 N; pH 8.5-8.8). The solution was pumped through a short coil of glass tubing at 100°C, and the mixture passed immediately into a coil (80 ft.) of 'Visking' tubing (8/32 in.) which returned to the heating coil, thus making a closed circuit. The dialysis tubing was inside a larger bore plastic tube carrying a slow stream of distilled water at 1-3°C. The reaction mixture was pumped continuously so that the whole of the mixture passed through the system every 2 h. This ensured that the longest heating time at 100°C for any portion of the mixture

before it passed to the dialysis system was about 20 min. Degradation continued for 90 days. The diffusate was evaporated under reduced pressure at a temperature not exceeding 40°C, and dried from the frozen state.

The diffusible material (5.2 g) dissolved in 20 ml. of water was passed through a column (81  $\times$  3.6 cm) of 'Sephadex G-15'. Fractions were examined for carbohydrate fragments by thin-layer chromatography on silica gel G, developed with *n*-propanol:ethyl acetate:water (6:1:3) (solvent *a*). Earlier inhibition studies indicated that an Le<sup>b</sup>-active fragment must be at least a tetrasaccharide, and the fractions were pooled according to their approximate molecular size, estimated by the movement on thin-layer plates of reference oligosaccharides of known molecular weight. Rechromatography of the selected materials on a column of 'Sephadex G-15' (157  $\times$  1 cm) gave a fraction with Le<sup>b</sup> activity which was shown by thin-layer chromatography in solvent (*a*) to contain components with  $R_{\text{lactose}}$  values varying from 0.45 to 0.9. Substances recovered (1.26 g) within this  $R_{\text{lactose}}$  range were chromatographed on a charcoal-celite column (59  $\times$  2 cm) using gradient elution with aqueous ethanol (0-20 per cent ethanol) maintained at pH 3 with formic acid<sup>26</sup>. The material eluted in the concentration range 2.5-4.0 per cent ethanol had Le<sup>b</sup> activity and contained two principal components. These fractions were pooled, neutralized by addition of 'Permutit De-Acidite FF-IP' (carbonate form), evaporated to a small volume and dried from the frozen state. The components in this mixture (72 mg) were separated by preparative chromatography on Whatman No. 40 paper developed with ethyl acetate:pyridine:water (2:1:2) (solvent *b*). The two principal fragments recovered had  $R_{\text{lactose}}$  0.27 (substance I; 14 mg) and 0.09 (substance II; 28 mg) on Whatman No. 4 paper in ethyl acetate:pyridine:water (10:4:3) (solvent *c*) and were both Le<sup>b</sup>-active. They each behaved as a single component when examined by chromatography on Whatman No. 4 paper in solvents (*a*), (*b*) and (*c*), by paper electrophoresis in borate buffer (pH 10) and by two-dimensional thin-layer chromatography in solvent (*a*) and butanol:ethanol:water (50:25:40). Substances I and II each yielded fucose, galactose and glucosamine on complete acid hydrolysis. The proportions of these sugars in the two substances (Table 1) and their chromatographic behaviour indicated that substance I was a tetrasaccharide and substance II a pentasaccharide.

The tetrasaccharide  $[\alpha]_D - 62^\circ$  (*c*, 1, water),  $R_{\text{lactose}}$  0.27 (solvent *c*),  $M_G$  0.25 (on paper electrophoresis in borate buffer at pH 10), did not react with alkaline triphenyltetrazolium chloride<sup>30</sup>, indicating that there was a substituent on carbon-2 of the reducing sugar unit. Products of reduction of the tetrasaccharide with sodium borohydride and hydrolysis with acid<sup>31</sup> contained no glucosamine, but yielded an equivalent amount (23.7 per cent) of glucosaminitol (estimation to be described elsewhere), indicating that the reducing sugar end unit in the tetrasaccharide was N-acetylglucosamine. The tetrasaccharide gave a negative indirect Ehrlich reaction<sup>32</sup> showing that there was a substituent on carbon-4 of the N-acetylglucosamine. Hydrolysis of the tetrasaccharide with N-acetic acid at 100°C for 2 h gave several sub-

Table 1. ANALYTICAL VALUES FOR THE Le<sup>b</sup>-ACTIVE TETRA- AND PENTASACCHARIDES BEFORE AND AFTER REDUCTION WITH SODIUM BOROHYDRIDE

	Tetrasaccharide				Pentasaccharide			
	<i>a</i>		<i>b</i>		<i>a</i>		<i>b</i>	
	%	Molar ratio	%	Molar ratio	%	Molar ratio	%	Molar ratio
Fucose	38.1	1.9	35.0	2.0	31.5	2.0	28.8	2.0
Galactose	21.5	1.0	18.9	1.0	32.4	1.9	21.1	1.3
N-Acetylglucosamine*	26.8	1.0	0	0	21.2	1.0	20.0	1.0

(*a*) Before reduction; (*b*) after reduction. Fucose was determined by the method of Gibbons<sup>37</sup>. For galactose, total sugar value was determined by the method of Dubois, Gilles, Hamilton, Rebers and Smith<sup>38</sup> after subtracting the amount of fucose in substance.

\* Calculated from the glucosamine value determined by the method of Rondle and Morgan<sup>39</sup>.

stances including the unchanged tetrasaccharide and fucose. A substance that gave a strong indirect Ehrlich reaction and a greenish colour with benzidine-trichloroacetic acid reagent<sup>33</sup> was chromatographically indistinguishable from lacto-*N*-biose I (*O*- $\beta$ -D-galactosyl-(1 $\rightarrow$ 3)-*N*-acetyl-D-glucosamine). *O*- $\beta$ -D-galactosyl-(1 $\rightarrow$ 6)-*N*-acetyl-D-glucosamine in the same conditions had a different  $R_{\text{lactose}}$  value and gave a reddish brown colour with the benzidine trichloroacetic acid reagent. *N*-acetyl-lactosamine (*O*- $\beta$ -D-galactosyl-(1 $\rightarrow$ 4)-*N*-acetyl-D-glucosamine) gave a golden yellow colour with this indicator, and did not react with Ehrlich's reagent after heating in alkali. A substance in the hydrolysis products ( $R_{\text{lactose}}$  0.95; Whatman No. 4 paper; solvent (c)) which gave a strong indirect Ehrlich reaction was believed, on the basis of its chromatographic behaviour, to be the H-active trisaccharide, *O*- $\alpha$ -L-fucosyl-(1 $\rightarrow$ 2)-*O*- $\beta$ -D-galactosyl-(1 $\rightarrow$ 3)-*N*-acetyl-D-glucosamine<sup>16</sup>. Another substance, also believed to be a trisaccharide ( $R_{\text{lactose}}$  0.57), gave no Ehrlich reaction after treatment with dilute alkali. This fact, combined with the observation that the acid hydrolysis products had  $\text{Le}^a$  serological activity not present before hydrolysis, suggested that it was the  $\text{Le}^a$ -active trisaccharide, *O*- $\beta$ -D-galactosyl-(1 $\rightarrow$ 3)-[*O*- $\alpha$ -L-fucosyl-(1 $\rightarrow$ 4)]-*N*-acetyl-D-glucosamine<sup>17</sup>.

Treatment of the tetrasaccharide with 5 per cent triethylamine in 50 per cent aqueous methanol at 80°C for 1 h gave products which failed to react with Ehrlich's reagent. With alkaline-silver nitrate reagent three spots, chromatographically identical with fucose,  $\alpha$ -L-fucosyl-(1 $\rightarrow$ 2)-galactose<sup>34</sup> and unchanged tetrasaccharide, appeared. An unidentified substance with  $R_{\text{lactose}}$  0.46 was also present. This evidence indicates the  $\text{Le}^b$ -active tetrasaccharide has the structure given in Fig. 1. Further evidence to support the structure was given by periodate oxidation and methylation. Oxidation with sodium metaperiodate<sup>35,36</sup> (Table 2) gave values for the consumption of periodate, production of the formic acid and the evolution of formaldehyde close to the expected values. After oxidation and reduction with sodium borohydride the tetrasaccharide gave 1 mole of formaldehyde. Methylation of the tetrasaccharide with methyl iodide in dimethyl formamide in the presence of BaO/Ba(OH)<sub>2</sub>·8H<sub>2</sub>O, by a modification<sup>37</sup> of the method of Kuhn *et al.*<sup>38,39</sup> followed by cleavage of the compound with 0.5 *N* hydrochloric acid in methanol at 80°C, gave a mixture of methylated glycosides which were examined by gas liquid chromatography. Peaks with retention times identical to the peaks given by authentic specimens of methyl-2,3,4-tri-*O*-methyl fucoside and methyl-3,4,6-tri-*O*-methyl galactoside were identified among the products, in agreement with the proposed structure.

The pentasaccharide ( $[\alpha]_D - 67^\circ$  (c, 1, water),  $M_G$  0.47,  $R_{\text{lactose}}$  0.09 on Whatman No. 4 paper in solvent (c)) was heated in *N*-acetic acid at 100°C for 5 h and the

Table 2. RESULTS OF THE OXIDATION OF THE  $\text{Le}^b$ -ACTIVE TETRA- AND PENTASACCHARIDES WITH 0.025 MOLAR SODIUM METAPERIODATE AT A pH OF ABOUT 5 FOR 24 H AT ROOM TEMPERATURE

Substance	Periodate consumed/mole of sample		Formic acid formed/mole of sample		Moles of formaldehyde released/mole of sample		Formaldehyde released/mole of sample after reduction	
	Found	Expected	Found	Expected	Found	Expected	Found	Expected
Tetrasaccharide	4.7	5.0	1.9	2.0	0.1	0.0	0.9	1.0
Pentasaccharide	6.1	6.0	2.0	2.0	0.3	0.0	1.9	2.0

products were run in solvent (c). Two spots reactive with the benzidine reagent<sup>33</sup> were identified as fucose and galactose respectively, and a third was chromatographically identical with the  $\text{Le}^b$ -active tetrasaccharide ( $R_{\text{lactose}}$  0.27 on No. 4 paper). A fourth substance ( $R_{\text{lactose}}$  0.49 on No. 1 paper) was considered on the basis of the following evidence to be the backbone trisaccharide, *O*- $\beta$ -D-galactosyl-(1 $\rightarrow$ 3)-*O*-(*N*-acetyl- $\beta$ -D-glucosaminyl)-(1 $\rightarrow$ 3)-D-galactose<sup>40</sup>. Hydrolysis of the pentasaccharide in 2*N*-acetic acid at 100°C for 18 h gave the same products as hydrolysis for 5 h and two additional substances with  $R_{\text{lactose}}$  1.15 and 1.49 (No. 1 paper). The faster running substance was chromatographically identical with lacto-*N*-biose I, and gave a strong indirect Ehrlich reaction. The slower running substance gave a positive indirect Ehrlich reaction, a positive reaction with triphenyl tetrazolium chloride reagent, and had the reported  $R_{\text{lactose}}$  value (1.15) of lacto-*N*-biose II (*O*-(*N*-acetyl- $\beta$ -D-glucosaminyl)-(1 $\rightarrow$ 3)-D-galactose).

The pentasaccharide heated with 5 per cent triethylamine in 50 per cent aqueous methanol<sup>40</sup> for 90 min at 80°C was largely degraded to *O*- $\alpha$ -L-fucosyl-(1 $\rightarrow$ 2)-galactose ( $R_{\text{lactose}}$  1.57; solvent (c)). In less severe conditions, at 40°C, the rate of degradation of the pentasaccharide was similar to that of the (1 $\rightarrow$ 3) linked disaccharide, *O*- $\alpha$ -D-galactosyl-(1 $\rightarrow$ 3)-D-galactose, and considerably faster than the rate of degradation of (1 $\rightarrow$ 4) linked lactose or (1 $\rightarrow$ 6) linked melibiose. The products of degradation after a 30 min run on No. 4 paper with the same solvent system gave some unchanged pentasaccharide ( $R_{\text{lactose}}$  0.08) and a substance ( $R_{\text{lactose}}$  0.26) chromatographically identical with the  $\text{Le}^b$ -active tetrasaccharide. More prolonged heating (3 h) in the same conditions gave *O*- $\alpha$ -L-fucosyl-(1 $\rightarrow$ 2)-D-galactose. The ready breakdown of the pentasaccharide to *O*- $\alpha$ -L-fucosyl-(1 $\rightarrow$ 2)-D-galactose in these mild alkaline conditions supports the conclusions reached on the basis of the evidence from the acid hydrolysis experiments that both glycosidic linkages in the principal chain are 1 $\rightarrow$ 3 linkages. None of the products of alkaline degradation gave positive reactions with Ehrlich's reagent. When the tetra- and the pentasaccharide were separately treated in the same mild conditions of degradation with alkali (1 h at 80°C with triethylamine), the tetrasaccharide no longer survived at a time when the pentasaccharide was still readily detectable.

In control experiments, lacto-*N*-difucohexaose I (I) heated with triethylamine at 65°C for 80 min gave products which chromatographically were shown to contain some unchanged lacto-*N*-difucohexaose I, and a substance with an  $R_{\text{lactose}}$  value identical with that given by the  $\text{Le}^b$ -active pentasaccharide run at the same time. More extensive degradation of the hexaose occurred on heating at 80°C for 1 h and the decomposition products examined by paper chromatography (solvent c) gave no spots with  $R_{\text{lactose}}$  values corresponding to the  $\text{Le}^b$ -active tetra- or pentasaccharide. In these conditions the hexaose was eroded as far as *O*- $\alpha$ -L-fucosyl-(1 $\rightarrow$ 2)-galactose.

The pentasaccharide was methylated<sup>37</sup> and the methanolysis products gave peaks on gas liquid chromatography with retention times identical with those detected in the methylation products of the tetrasaccharide, and, in addition, peaks corresponding to methyl-2,4,6-tri-*O*-

Fig. 1. Structure of the  $\text{Le}^b$ -active tetrasaccharide *O*- $\alpha$ -L-fucosyl-(1 $\rightarrow$ 2)-*O*- $\beta$ -D-galactosyl-(1 $\rightarrow$ 3)-[*O*- $\alpha$ -L-fucosyl-(1 $\rightarrow$ 4)]-*N*-acetyl-D-glucosamine.

isolation and characterization of the H and Le<sup>a</sup> determinants<sup>34,35</sup> established the positions and linkages of the fucose residues and indicated that the H gene controls the addition of fucose to the carbon-2 position of a terminal non-reducing  $\beta$ -galactosyl residue in either the type 1 or type 2 chains, whereas the Le gene transferase adds fucose to the carbon-4 position of the subterminal  $\beta$ -N-acetylglucosaminyl residue of the type 1 chain. The chemical characterization of the Le<sup>b</sup>-active oligosaccharides isolated from an HLe<sup>b</sup> substance (Figs. 1 and 2) as structures with two fucose units joined to adjacent sugars—one fucose linked as in H determinants and the second as it occurs in the Le<sup>a</sup> determinant—thus supports the interpretation that the Le<sup>b</sup> determinant is an interaction product of the H and Le genes. The structure formed by the presence of the two fucose residues, although compounded of the H and Le<sup>a</sup> active groupings, has neither H nor Le<sup>a</sup> specificity; instead it has the new specificity, Le<sup>b</sup>, which is different from that produced by either one of the H or Le genes acting in the absence of the other. An Le<sup>b</sup> gene is not therefore required to account for the appearance of Le<sup>b</sup> activity. It is to be noted that of the two types of chain known to occur in the blood-group specific glycoproteins, only one, namely the type 1 chain, can give rise to an Le<sup>b</sup> specific structure. In the presence of H and Le genes the type 2 chains have only the fucose added by the H gene, and are therefore H-active. Type 1 and 2 chains occur in the same macromolecule and so it is understandable that it has not been possible to isolate from secretions glycoproteins which have only Le<sup>b</sup> activity.

The first examples of red blood cell antigens that were peculiar to the hybrid and occurred in neither of the homozygous parental types were reported in doves<sup>17,18</sup>. Hybrid antigens have also been described in pigeons<sup>19</sup>, ducks<sup>20</sup> and rabbits<sup>21</sup>. In man there is evidence that antibodies are occasionally formed to compound antigens in the Rh blood-group system<sup>21</sup> and to interaction products of the gene I with the A, B or H genes<sup>21,22</sup>. The only hybrid blood-group active molecules that have been clarified in chemical terms, however, are the products formed in heterozygous group AB persons<sup>23</sup>, and the example described here. The human blood-group alleles A and B acting together in "secretor" persons of genotype AB give rise to a glycoprotein that has A and B specific structures in the same molecule<sup>23</sup> but the A and B characters are each expressed and no new serological specificity is formed. We believe that the reason why the serological A and B specificities remain distinct, even when superimposed on the same molecule, is that the A- and B-active structures cannot be present together at the end of the same carbohydrate chain<sup>20</sup>. The macromolecules therefore have some chains ending in A-active groupings, and others in B-active groupings, and the spatial pattern is presumably such as to allow access of the appropriate A- or B-specific antibodies. This type of hybrid molecule therefore differs from the one described in the present paper in which each gene, H and Le, acts independently to elicit its own specific structure but, presumably because the structural contributions occur in close proximity on the same carbohydrate chain, a new spatial pattern is formed that is reflected in a new antigenic specificity. By the same token the H- and Le<sup>a</sup>-specific antibodies are probably prevented sterically from approaching their homologous antigenic groupings, and thus the original specificities are lost.

The chemical characterization of the two types of hybrid molecules arising in the glycoproteins associated with ABH and Lewis blood-group specificity thus illustrate the diversity of products that may be expected for genetically controlled antigens in which the specific structures are carbohydrate. The tenet of "one gene, one antigen", at one time widely held in the field of human blood groups, has to be abandoned. Similarly the concept that a child cannot have a blood-group antigen not present in either

of its parents is seen to be only a partial truth. Nevertheless, the proposed mechanism for the formation of these hybrid antigens, whereby the individual genes give rise to specific enzymes responsible for single biosynthetic steps in the formation of complex carbohydrate structures, in no way conflicts with the present ideas on the molecular basis of gene action.

We thank Professor R. Kuhn for specimens of milk oligosaccharides, and Dr Sturgeon, Dr Barbara Dodd and the staff of the MRC Blood Group Reference Laboratory for anti-Le<sup>a</sup> and anti-Le<sup>b</sup> sera. One of us (A. M. S. M.) thanks the governing body of The Lister Institute for the award of the Morna Macleod Research Studentship. The work was supported in part by a grant from the Medical Research Council.

# Protein Components of Encephalomyocarditis Virus

by

A. T. H. BURNES

D. S. WALTER

Virus Research Unit,  
Medical Research Council Laboratories,  
Carshalton, Surrey

Chemical and physical studies of protein extracted from highly purified EMC virus suggest that at least three sorts of polypeptide chain are present in EMC and perhaps other picornaviruses. They may therefore differ fundamentally in structure from icosahedral plant viruses of similar size, such as TYMV.

THE information contained in the RNA of a virus is not enough to code for a single protein the size of the virus shell, or capsid. Crick and Watson<sup>1</sup> thus originally suggested that such a shell must be built up of smaller, identical, sub-units, which have since been generally assumed to consist of single proteins. In support of this suggestion several plant viruses, including tobacco mosaic virus<sup>2</sup> and turnip yellow mosaic virus<sup>3</sup>, seem to contain only one kind of polypeptide chain. Small animal viruses, however, may not obey the same rules, for protein extracted from several members of the picornavirus family, notably poliovirus<sup>4</sup> and viruses of the Columbia SK group<sup>5,6</sup>, gave more than one component when examined by polyacrylamide gel electrophoresis. Electrophoretic heterogeneity might arise from one of the following causes. (1) The virus protein might be contaminated with cell protein or with proteins from mutant forms of the virus also present in the preparations. The components might be artefacts produced either by (2) chemical modification during investigation of certain amino-acids in the virus protein or (3) by aggregation or breakdown of a single protein. (4) The virus might have contained more than one sort of polypeptide chain.

The present work, which has been carried out using protein obtained from cloned, rigorously purified encephalomyocarditis (EMC) virus, confirms the presence of more than one electrophoretic component of distinct amino-acid composition. It has now been shown that these components are of approximately the same size, before or after electrophoresis, with no sign of the existence of a larger precursor. The evidence obtained therefore supports the contention that the virion of this picornavirus contains more than one distinct polypeptide chain.

EMC virus protein, like that from several icosahedral viruses<sup>3,6</sup>, was relatively insoluble in common aqueous buffers tending to produce aggregates, possibly by disulphide bond formation. The sulphhydryl groups of the protein used in the present study were therefore blocked by carboxymethylation by the presence of iodoacetate during phenol extraction of the protein from the virus<sup>6</sup>. At the same time a radiochemical marker was introduced into the protein by carboxymethylating either with  $1\text{-}^{14}\text{C}$ -iodoacetamide or with  $2\text{-}^3\text{H}$ -iodoacetic acid (Radiochemical Centre, Amersham). Radioactivity was measured either in a Packard 'Tri Carb' or in a Beckman scintillation spectrometer in a dioxan based solvent<sup>7</sup>. At least four components were revealed by amido black staining when this carboxymethylated (CM) protein was examined in a Shandon analytical polyacrylamide gel electrophoresis apparatus using either 7.5 per cent or 15 per cent gel in the pH 4.3 acetate system of Reisfeld *et al.*<sup>8</sup> with 8 M urea in all solutions except the top reservoir (Fig. 1a).

When an unstained gel, immediately after electrophoresis, was immersed either in 50 per cent ammonium sulphate (Dr R. Martenson, personal communication) or in acetate buffer (pH 4.8), the isoelectric point of EMC virus revealed at least three white bands of precipitated protein (Fig. 1b); with this procedure, there was no band corresponding to the band 3 revealed by amido black staining, which immediately suggests that it contains material different from that in the other three bands. The three components 1, 2 and 4 have been studied in the present work and were obtained by cutting out the white bands, homogenizing in 67 per cent acetic acid and, after removing the gel by filtration, precipitating with 6 volumes of ethanol. These results confirmed previous observations that EMC virus CM-protein show electrophoretic heterogeneity. The next step was to investigate the origin of this heterogeneity.

*Contamination with protein from mutants or host cells.* We used virus consisting of a large plaque variant derived by four successive plaque isolations from the K2 strain<sup>9</sup> of EMC virus. The virus was grown in suspension cultures of Krebs 2 ascites tumour cells<sup>10</sup> and purified by a method (to be published) involving acid precipitation followed by organic solvent extraction, enzyme treatment and dif-

Fig. 2. Relationship between distance moved by serum albumin and time of centrifugation on a 5-20 per cent sucrose gradient containing 8 molar urea and 0.1 molar acetate buffer, pH 4.3.

ferential centrifugation. The extent of purification was monitored by the addition of non-infected cell material labelled either with  $^3\text{H}$  amino-acids or with  $^{32}\text{P}$ , as markers for cell protein or nucleic acid, respectively. As little as 0.014 per cent  $^3\text{H}$  and 0.0038 per cent  $^{32}\text{P}$  was recovered, but 60 per cent of the biological activity was recovered which indicates that a high degree of purity had been achieved. The use of virus purified both biologically and chemically in this way means that it is unlikely that the electrophoretic heterogeneity observed was due to contamination with protein from either host cell or mutant virus particles.

Table 1. AMINO-ACID COMPOSITION OF COMPONENTS OF EMC VIRUS CM PROTEIN SEPARATED BY POLYACRYLAMIDE GEL ELECTROPHORESIS

Amino-acid	Moles amino-acid per 100 moles amino-acid recovered		
	Component 1	Component 2	Component 4
Asp	8.9	10.1	8.6
Thr	7.0	10.0	9.6
Ser	13.0	10.6	8.7
Glu	10.7	9.5	9.0
Pro	5.3	8.8	7.1
Gly	15.1	10.5	9.8
Ala	6.7	7.3	8.4
Val	5.4	8.1	7.0
Ile	3.1	3.6	4.2
Leu	6.3	8.1	7.0
Tyr	1.7	3.4	3.2
Phe	4.4	8.1	5.4
Lys	4.9	5.2	4.5
His	3.0	2.1	2.4
Arg	4.4	4.1	4.1

**Chemical modification.** The alteration of a single amino-acid in part of the material might lead to charge heterogeneity which could be detected by gel electrophoresis and so be interpreted falsely as demonstrating the presence of more than one sort of polypeptide chain. Among the chief hazards in gel electrophoresis are oxidation of amino-acids such as tryptophan or cysteine by the persulphate<sup>11</sup> used in the polymerization, carbamylation<sup>12</sup> of the  $\epsilon$ -amino group of lysine by the cyanate which can contaminate the urea in electrophoresis buffers and desamidation of asparagine and glutamine residues. Precautions can be taken to reduce these hazards by running mercapto-ethanol in the gel to remove excess persulphate or by deionizing the urea immediately before use on a mixed bed resin such as Permutit "Deminrolit". If, however, the electrophoretic components differ in composition in those amino-acids which are not usually susceptible to modification, then presumably the components are distinct entities and are not artifacts of the handling procedure. Amino-acid analysis of the isolated components (Table 1) suggested that components 2 and 4, although broadly similar, differed in their content of phenylalanine—an amino-acid not susceptible to modification. Component 1,

however, differed considerably from components 2 and 4 and would appear to be an unrelated polypeptide. This evidence suggests therefore that EMC virus CM protein contains more than one kind of polypeptide chain. Differences have also been demonstrated by Rueckert and Duesberg<sup>13</sup> in amino-acid composition of electrophoretic components in ME virus protein.

**Aggregation or breakdown.** Proteins from poliovirus<sup>4</sup> and ME virus<sup>6</sup> have been reported as moving as a single peak when examined in alkaline buffers containing sodium dodecyl sulphate (SDS) in an analytical ultracentrifuge, thus presumably demonstrating the absence of aggregates and of possible breakdown products. The electrophoretic components had, however, been demonstrated in acetate buffer, pH 4.3 containing 8 M urea, so the possibility exists that heterogeneity in this buffer arose either from breakdown or from aggregation, but that such changes did not take place in the alkaline-SDS buffer used for analytical ultracentrifugation and so were not detected. This objection can be answered either by carrying out the electrophoresis and sedimentation studies in the same buffer or by isolating the separated components and demonstrating, by measuring their size, that aggregation or breakdown was not a factor leading to electrophoretic separation.

Examination of EMC CM-protein in sodium dodecyl sulphate buffer (0.1 per cent SDS-0.05 M sodium borate-0.1 M sodium chloride adjusted to pH 10.5 with sodium hydroxide) at 20° in a Beckman-Spinco Model E ultracentrifuge using schlieren optics showed a single, homogeneous peak of sedimentation coefficient 2.7S, a value identical to that obtained for ME virus CM protein by Rueckert<sup>6</sup> but which differs slightly from the figure of 2.0S obtained by Maizel<sup>4</sup>. This examination confirmed that the size of the protein extracted from EMC virus was similar to that obtained from other picornaviruses.

Because the electrophoretic components had already been demonstrated in acetate buffer, pH 4.3 containing 8 M urea, this solvent was also used for ultracentrifugal examination of EMC CM-protein. Zonal ultracentrifugation in a Beckman-Spinco Model L ultracentrifuge with an SW 39 rotor, using a serum albumin marker on sucrose gradients, was chosen, because it could give an estimate of size<sup>14</sup> and yield material for further study. Centrifugation for 72 h was necessary, and to ensure that the protein would not be retarded by the dense solvent used as it approached the bottom of the tube, a control investigation was carried out to show that a plot of the position of serum albumin against the time of centrifugation was a straight line over the period required (Fig. 2). The virus protein ran under the same conditions as a single peak of radioactivity of molecular weight  $30,000 \pm 3,600$  compared with serum albumin in the same tube (Fig. 3). This value

Fig. 3. Sucrose density gradient centrifugation in urea-acetate buffer of EMC virus  $^3\text{H}$ -CM protein (x---x) with serum albumin (O—O) as an optical density marker.

is similar to that obtained for poliovirus and ME virus proteins by Maizel<sup>4</sup> and Rueckert<sup>5</sup>, respectively, but disagrees with the figure of a molecular weight of 42,000 for poliovirus protein obtained by Boeyé<sup>15</sup>. These three previous determinations were made in SDS in alkaline buffer. Hamilton *et al.*<sup>16</sup> obtained a value of 60,000 for the molecular weight of an antigenically active sub-unit prepared from EMC virus and examined by agar gel diffusion.

Thus in the present work there was no sign of aggregation or breakdown in either SDS-buffer or in acetate-urea, and yet electrophoretic heterogeneity existed. It was decided therefore to examine the electrophoretic components individually on sucrose gradients to check whether the technique of electrophoresis was giving rise to artefacts.

Table 2. MOLECULAR WEIGHTS ESTIMATED BY SUCROSE DENSITY GRADIENT CENTRIFUGATION OF EMC VIRUS PROTEIN COMPONENTS SEPARATED BY ELECTROPHORESIS ON ACRYLAMIDE GEL

Component	Molecular weight
1	32,500 $\pm$ 3,400
2	29,300 $\pm$ 1,900
4	30,300 $\pm$ 3,000

Because components of different size were being sought, electrophoresis was performed using 15 per cent acrylamide gels on which separation is related more to size and shape rather than charge<sup>17</sup>. The three principal bands revealed by iso-electric precipitation (Fig. 1b) were individually centrifuged on sucrose density gradients in urea-acetate buffer. Although component 1 appeared to be consistently larger than components 2 and 4, the molecular weights thus obtained fell within the range of experimental error (Table 2). This result, together with the amino-acid differences (Table 1), would seem to exclude the possibility that the electrophoretic components were aggregates. It is difficult to be certain that these components did not arise from breakdown of a larger molecule. If, however, it occurs, conversion into smaller units must be remarkably complete, for no indication of a larger precursor molecule was seen; moreover, if breakdown takes place, all its products appear to be of similar size. Furthermore, Rueckert and Duesberg<sup>13</sup>

looked for, but could not find, N-terminal amino-acids in ME virus protein; breakdown of a polypeptide chain could be expected to yield detectable ends.

This evidence thus leads to the conclusion that EMC and perhaps other picornaviruses contain three or more types of polypeptide chains of similar size and therefore may differ fundamentally in structure from the icosahedral plant viruses of similar size, such as TYMV, which appear to have only one type of protein<sup>3</sup>. We cannot as yet equate these polypeptide chains with specific morphological structures within the picornavirus particle, nor is it known whether all the polypeptides detected comprise parts of the virus capsid or whether a core protein exists. The relationship between these polypeptides and the haemagglutinin which is found in many picornaviruses also remains uncertain. These latter problems are currently under investigation.

We are grateful to Dr F. K. Sanders for his interest and criticism, Miss Joy Moss for preparing the virus, and Miss Ingrid Pardoe and Mr F. W. Clothier for the amino-acid analyses.

## Secondary Crossing-over

by

H. L. K. WHITEHOUSE\*

Department of Botany,  
University of Cambridge

Secondary crossing-over between alleles seems to arise as a consequence of modifications of the normal crossover mechanism caused by a particular mutation. Interference between crossovers is believed to be polarized in relation to the centromere, but secondary crossovers are thought not to interfere with one another. Possible causes of postmeiotic segregation, which is sometimes associated with secondary crossing-over, are discussed.

RECIPROCAL recombination of linked mutants could arise in two ways. One possibility (crossing-over) is the inclusion in the interval between the mutant sites of the whole of the hybrid DNA segments which make up a crossover. This would be the usual explanation of reciprocal recombination of mutants well separated on a chromosome. The other possibility (reciprocal conversion) is the correction of mispairing in opposite directions in the two chromatids when a mutant site is within the hybrid DNA segments of a crossover. Evidence is presented here that when two allelic mutants show reciprocal recombination, this usually results from an entire crossover in the interval

between their sites, and not from reciprocal conversion at the site of one of them.

Evidence suggests that crossing-over is initiated from one end of a gene, but in this case an entire crossover between sites within a gene should be impossible. This paradox is resolved by regarding crossing-over between alleles as abnormal. The name secondary crossing-over is proposed for the process, because there is evidence that the crossover can be initiated normally and be modified subsequently by the presence within the gene of a particular kind of mutation.

I suggest that crossing-over is initiated when the phosphodiester backbones of newly synthesized nucleotide chains of DNA fail to join across the operator of a gene<sup>1,2</sup>.

\* Present address: Division of Biology, Southwest Center for Advanced Studies, Dallas, Texas.

Hybrid DNA extends from this opening point at the operator over a part of or the whole gene in homologous chromatids. If a site of mutation, differing in each parent, was within the regions of hybrid DNA of the crossover, this would lead to mispairing in the DNA. Uncorrected mispairing would cause segregation of the corresponding character difference at first mitosis after meiosis (postmeiotic segregation). The mismatching might also be repaired by replacing one of the nucleotides of the pair by a nucleotide complementary to that in the other chain. In each chromatid this correction might be to mutant or to wild type, depending on which mispaired nucleotide was replaced in each molecule. If correction were in the same direction in both chromatids (that is, to mutant in both, or to wild type in both), the mutant would show non-reciprocal recombination with other mutants. For example, if two linked mutant differences are denoted by *A* and *a*, and *B* and *b*, respectively, and if the parental genotypes were *AB* and *ab*, hybrid DNA at the site of the *A/a* difference would give a tetrad of genotype *AB*, *A/a B*, *A/a b*, *ab*, initially. After correction of mispairing in the same direction in both chromatids, the four products of meiosis would be either *AB*, *AB*, *Ab*, *ab*, or *AB*, *aB*, *ab*, *ab*. The process giving rise to such non-reciprocal recombination has been called conversion.

If correction of mispairing took place in opposite directions in the two chromatids—to mutant in one and to wild type in the other—either a parental or a reciprocal non-parental arrangement with the other mutant would result; the four products of meiosis would be either *AB*, *AB*, *ab*, *ab*, or *AB*, *aB*, *Ab*, *ab*. This origin of reciprocal recombination is described here as reciprocal conversion, because the steps involved are essentially the same as those postulated to explain non-reciprocal recombination.

If the hybrid DNA segments of a crossover were of unequal length in the two chromatids, so as to reach a mutant site in only one of them, either a parental genotype or a non-reciprocal recombinant genotype for the tetrad would result. The alternatives depend on the direction of correction of the mispairing. Thus if the tetrad genotype were *AB*, *A/a B*, *ab*, *ab* after hybrid DNA formation, it would be either *AB*, *AB*, *ab*, *ab*, or *AB*, *aB*, *ab*, *ab*, after correction. Conversely, if the initial hybrid genotype were *AB*, *AB*, *A/a b*, *ab*, correction could give either *AB*, *AB*, *Ab*, *ab* or *AB*, *AB*, *ab*, *ab*. It is not possible to obtain reciprocal recombination of two mutant differences by this means.

Postmeiotic segregation and conversion, thought to be associated with a mutation within the hybrid DNA segments of a crossover, appear to occur also in the absence of crossing-over. A review of published data is illustrated by Table 1 (ref. 3), together with further data for the gene *pan-2* in *Neurospora crassa*<sup>8</sup>, and the extensive data for the gene *hi-1* in *Saccharomyces cerevisiae*<sup>13</sup>. The *hi-1* data show a progressive decline in the frequency of

parental combinations with proximity of the mutant site to the distal end of the gene with respect to the centromere. The frequencies of parental arrangements for the outside markers range from 36 to 64 per cent for the mutants given in Table 1 for which appreciable data are available. I consider<sup>1</sup> that these parental combinations are caused by a second or reverse crossover adjacent to the first one and involve the same two chromatids. Such a crossover would nullify the effects of the first one, as far as outside markers are concerned, and lead to parental arrangements of them.

Table 1. BEHAVIOUR OF OUTSIDE MARKER GENES WHEN A MUTANT SHOWS EITHER POSTMEIOTIC SEGREGATION OR NON-RECIPROCAL CONVERSION

Species	Locus and reference	Arrangement of outside markers			Per cent parental
		Parental	Recombinant	Total	
<i>Neurospora crassa</i>	<i>pdx-1</i> (ref. 4)	3	1	4	75
	<i>pyr-3</i> (ref. 5)	2	0	2	100
	<i>pan-2</i> (refs. 6-9)	17	15	32	53.1
	<i>cys</i> (refs. 10 and 11)	29	19	48	60.4
<i>Sordaria fimicola</i>	<i>g</i> (ref. 12)	78	44	122	63.9
<i>Saccharomyces cerevisiae</i>	Allele 315	227	168	395	57.5
	<i>hi-1</i> (ref. 13)	252	200	452	55.8
	204	10	14	24	41.7
	1	39	70	109	35.8

The data for each gene in *Neurospora* refer to more than one allele. Fogel and Hurst's data for *hi-1* in *Saccharomyces* refer in descending order to the alleles Nos. 315, 7, 204 and 1. This is the sequence of the sites within the gene, starting at the proximal end with respect to the centromere.

Two facts suggest that reciprocal recombination of alleles usually results from an entire crossover between the sites of the mutants, and not from reciprocal conversion. Reciprocal recombination of alleles seems to be associated most often with a non-parental outside marker arrangement, and, furthermore, with the particular arrangement expected from crossing-over in the interval between the sites of the allelic mutants. Published data on the behaviour of outside markers when alleles show reciprocal recombination are given in Table 2; they refer to three species of fungi and include mitotic as well as meiotic recombination. All results are similar and indicate that approximately 7 per cent of reciprocal recombinations of alleles show a parental arrangement of outside markers. This is in striking contrast to the data in Table 1, which show that postmeiotic segregation and non-reciprocal conversion are associated with parental marker combinations five to nine times as often. Reciprocal conversion is expected to be similar because, like postmeiotic segregation and non-reciprocal conversion, it is associated with the presence of a mutant within a region of hybrid DNA. More than 90 per cent of the reciprocal recombinations of alleles in Table 2 had the configuration expected if the recombination of the outside markers was caused by that of the alleles. It seems likely therefore that only about 10 per cent were caused by reciprocal conversion, and the remainder by an entire crossover in the interval between the sites of the allelic mutants.

Table 2. BEHAVIOUR OF OUTSIDE MARKER GENES WHEN ALLELES SHOW RECIPROCAL RECOMBINATION

Species	Locus and reference	Alleles crossed (proximal on left, distal on right)	Arrangement of outside markers			
			A Parental with extra recombination proximal to alleles	B Parental with extra recombination distal to alleles	C Crossover coinciding with alleles	D Crossover with extra recombination proximal and distal to alleles
<i>Aspergillus nidulans</i> (mitotic recombination)	<i>ad-8</i> (ref. 14)	20 × 8	0	0	3	0
		16 × 8	0	1	8	0
	<i>ad-9</i> (ref. 15)	33 × 13	0	0	1	0
		13 × 9	1	1	0	0
		13 × 32	1	1	4	0
		13 × 15	0	0	4	0
	<i>paba-1</i> (ref. 16)	5 × 2	0	0	1	3
		5 × 15	0	1	4	0
<i>Neurospora crassa</i> (meiosis)	<i>pan-2</i> (refs. 6 and 8)	5 × 18	0	1	8	0
		2 × 19	0	0	1	1
		5 × 3	0	0	2	0
		23 × 72	0	0	2	0

		315 × 204	0	0	3	0
		315 × 1	1	0	21	0
		7 × 1	3	0	73	0
		Total	6	5	147	5

The pattern of hybrid DNA within the gene also suggests that reciprocal recombination of alleles is not usually brought about by conversion. Reciprocal conversion is, after all, only possible if, in both chromatids, there is hybrid DNA at the mutant site. At many mutant sites, however, the hybrid DNA seems to be confined to one chromatid. The work of Lissouba *et al.*<sup>18</sup> with ascospore colour mutants of *Ascobotus immersus* illustrates this. Mutants Nos. 63 and 138 in series 46 show only non-reciprocal recombination when crossed with one another. As indicated earlier, hybrid DNA confined to one chromatid at a mutant site would explain this (see Fig. 1a). If there was hybrid DNA in both chromatids at the site of 138, as in Fig. 1b, double mutant spores would arise when there was correction of mispairing to 138 instead of to wild type, but none was found. It is inferred that the lack of reciprocal recombinant asci results from the absence of reciprocal conversion, and that this is because

the hybrid DNA is confined to one chromatid at the site of 138. A similar argument applies to asci showing post-meiotic segregation from a cross between mutants Nos. 63 and 277. If there was hybrid DNA at the site of 277 in both chromatids, as in Fig. 1f, some asci with one or two double mutant spores would be expected when correction of mispairing failed to occur or went in favour of 277, but none was found.

An entire crossover, while seeming to be possible between alleles, appears to differ in at least four respects from the normal crossover. First, it seems to be specific to particular mutants, and there is no evidence that normal crossing-over shows any such specificity. Reciprocal recombination of alleles appears in general to be much less frequent than non-reciprocal. The most extensive data on the relative frequencies of the two phenomena are from the work of Lissouba *et al.*<sup>18</sup>, who showed that reciprocal recombination of mutants from the same series

Fig. 1. Diagram of possible modes of origin of recombinant ascus genotypes obtained<sup>18</sup> by selecting asci with dark (wild type) spores from crosses between pale-spored mutants belonging to series 46 in *Ascobotus immersus*. The genotypes of the eight spores in the asci are shown in the centre column, and possible explanations of their origin are shown on either side, with a more probable alternative to the left and a less probable to the right in each instance. (a and b) Cross between mutants 63 and 138, (c-h) between mutants 63 and 277. The rectangles represent chromatids (which are considered to be equivalent to a DNA molecule), and the horizontal arrows show the extent of formation of hybrid DNA from an opening point at the right-hand end of the gene. This point is shown either by a dot or by a vertical line joining the two chromatids. Correction of mispairing is indicated by an oblique arrow through the excised allele. (g) Where there is secondary crossing-over, the broken lines show the region where hybrid DNA is thought to have existed only temporarily.

varies greatly in frequency from one pair of mutants to another. Many fail to show reciprocal recombination, and its occurrence seems to be characteristic of certain mutants. This is particularly clear with mutant 277 in series 46 already discussed. Similar variation is evident in the more limited data available from study of nutritional mutants in *Neurospora*. No reciprocal recombination of *cys* alleles was found<sup>11</sup>. On the other hand, frequent reciprocal recombination is a likely explanation for the high frequency of crossing-over for outside markers found when mutant No. 1710 at the *hist-3* locus was crossed with alleles and prototrophs were selected<sup>10</sup>.

Second, when crossing-over occurs between alleles, neither mutant site lies within hybrid DNA, because the mutants show neither postmeiotic segregation nor conversion. Evidently, the hybrid DNA segments may be quite short. A total of 256 recombinant asci of *Ascobolus*, heterozygous at three sites in series 75, have been analysed<sup>20</sup>. The two outer mutants were chosen because of their high frequency of reciprocal recombination with other mutants of the same series. All 256 asci showed reciprocal recombination of the outer mutants and sixty of them showed conversion at the intervening site. The hybrid DNA segments of a crossover between alleles may include the site of an intervening allele. This agrees with the fact that when mutants associated with reciprocal recombination were crossed individually with other mutants of the same series, the proportion of recombinant asci in which the recombination was reciprocal increased with increasing separation of the mutant sites. Studies of this kind should permit an estimate of the length of the hybrid DNA segments and their range of variation. A crossover between alleles may occupy a fraction of the length of a gene, which is probably considerably shorter than the usual length of hybrid DNA in a normal crossover, where the hybrid region is thought often to extend through one gene and into the next<sup>1</sup>.

Third, the hybrid DNA in a crossover between alleles does not extend to a normal opening point at the end of a gene. In normal crossing-over the data are consistent with dissociation of the DNA always being initiated only at an opening point at one particular end of a gene<sup>1</sup>.

Fourth, reverse crossovers do not seem to have taken place in association with crossovers between alleles. With normal crossing-over, reverse crossovers<sup>1</sup> are thought to occur regularly as a result of dissociation of the nucleotide-chains, chain synthesis and hybrid DNA formation from the same opening point as the primary crossover but in the opposite direction along the DNA molecule. As already discussed, this would explain intragenic recombination phenomena associated with a parental combination of outside markers. But with reciprocal recombination of alleles, evident from the data in Table 2, parental arrangements of outside markers are rare and can probably be explained by reciprocal conversion within the hybrid DNA regions of a normal crossover.

Despite these differences from normal crossing-over, there are two reasons for believing that crossing-over between alleles is initiated in the normal way. Mutant 277 in series 46 of *Ascobolus* shows reciprocal recombination with other mutants of the same series only when crossed with mutants placed to its left on the map<sup>18</sup>. When crossed with mutant No. 138, which to judge from recombination frequencies is to its right on the map (compare Fig. 1), the recombinant asci showed conversion at the site of 138 only (and once at the site of 277 only), but there was no reciprocal recombination of the mutants. Furthermore, in three-point crosses involving mutants 63, 277 and 138, there was no reciprocal recombination between any of the mutants in ten recombinant asci which were analysed: all showed conversion at the site of 138 only, as in the cross between 63 and 138 discussed here. For reciprocal recombination, it seems to be necessary to have the same condition which is needed with every series 46 mutant in order to obtain either postmeiotic

segregation or conversion at its site, namely that the mutant should be the right-hand member of those crossed. It is inferred from this that hybrid DNA is initiated only from the right-hand end of the gene, and that because of linked correction of mispairing (that is, correction of neighbouring sites to the same parent—compare ref. 8), selection for recombination of alleles implies selection for hybrid DNA ending before it has reached a left-hand site. It seems that, for the occurrence of the reciprocal recombination which is associated with 277 and which takes place to its left on the map, hybrid DNA has to arise in the normal way from the right-hand end of the gene.

The mutant specificity of crossing-over between alleles is the second reason for believing that this crossing-over is initiated in the normal way, through opening of the DNA at the end of the gene. It is difficult to understand how any peculiarity of a mutant could influence the course of the recombination process until hybrid DNA has formed, or attempted to form, because the chromatid carrying the wild type allele is necessarily involved as much as that with the mutant.

I conclude that in crossing-over between alleles the initial steps are normal, that is, the gene is opened from an end, synthesis of new chains occurs along the unbroken chains, the new chains dissociate from their templates, and then hybrid DNA begins to form, also from the end. The mutant may become incorporated into hybrid DNA, leading to either postmeiotic segregation or conversion (compare Fig. 1e and c). Alternatively, because of some peculiarity of the mutant, the process of crossing-over may take an abnormal course, with the mutant excluded from hybrid DNA. The details are uncertain, but the apparent result is that there is hybrid DNA on the far side of the mutant from the opening point, that is, between the sites of the two allelic mutants, while the parental situation, without hybrid DNA, is restored on the near side, that is, between the site of the first mutant and the opening point. This apparent reversal of hybrid DNA formation in the interval between the site of the first mutant and the end of the gene is indicated by broken lines in Fig. 1g. In view of these arguments for believing that crossing-over between alleles arises secondarily, as a consequence of modifications of the normal crossover mechanism caused by a particular mutant, it is proposed to call the process secondary crossing-over.

A peculiarity of secondary crossing-over is the lack of parental outside marker arrangements in conjunction with it. If with normal crossing-over parental combinations arise by reverse crossing-over, and if the reverse crossovers arise after the primary crossovers, it is likely that the mechanism of enzyme recognition of the primary crossover depends on the form which the nucleotide chains took at the opening point, because this is where the reverse crossover would be initiated. As indicated here, secondary crossovers are thought not to have the crossover configuration at the opening point, because the hybrid DNA seems to be confined between the sites of the mutations. It is possible therefore that a secondary crossover might not be recognized by the crossover-reversal enzyme. This would explain the lack of parental outside marker combinations with secondary crossing-over.

The places where DNA is opened for recombination seem to be distributed at random along the chromosome (apart from always being at the ends of genes)<sup>3</sup>, and interference seems to have been caused by potential crossovers in the neighbourhood of an existing crossover being influenced by it and switched to the double crossover path. According to this hypothesis of interference, secondary crossovers would be expected to show no interference with one another, assuming that reverse crossovers fail to form in association with them.

The occurrence of reciprocal recombination of alleles at the *hi-1* locus in *Saccharomyces* showed no interference with crossing-over in a region 2.4 units long adjacent to *hi-1* on its proximal side with respect to the centromere<sup>13</sup>.

On the other hand, there was strong interference with crossing-over in an interval 9.9 units long adjacent to *hi-1* on its distal side, and a significant though lesser reduction in crossing-over in a further region 19.3 units long beyond the 9.9 interval. This would be accounted for if the crossover-reversal enzyme always moved distally, that is, away from the centromere and towards the end of the chromosome arm. A crossover within *hi-1* would then be unable to reverse a crossover on its proximal side. Such polarity in interference would also explain the discovery<sup>21</sup> that in *Drosophila* crossovers seem to arise in sequence along each chromosome arm starting from the centromere. Furthermore, the relationship<sup>22</sup> between the position of crossovers induced by ultra-violet light and the time in the nuclear cycle of the irradiation could be similarly explained. Diploid cells of *Ustilago maydis* treated with ultra-violet light late in DNA synthesis, unlike earlier treatment, show mitotic crossing-over mostly near the centromeres. Holliday suggested that a particular phase of DNA replication was sensitive to the induction of crossing-over, and that this phase moved progressively from the end of each chromosome arm to the centromere. On the other hand, a crossover-reversal enzyme moving in the opposite direction would seem to offer an alternative explanation, because crossovers formed after its passage could not be reversed and so would accumulate near the centromeres.

The hypothesis that interference shows polarity determined by the centromere, and that secondary crossovers are immune to interference, could be tested if a paracentric inversion included the sites of a pair of alleles showing secondary crossing-over and if flanking markers were available.

To understand the process of secondary crossing-over, it is necessary to know the peculiarity of mutants which cause it. According to existing data<sup>18,23,24</sup> several of the ascospore colour mutants in *Ascomobolus* which show reciprocal recombination with members of the same series also show one or both of two other phenomena, that is, postmeiotic segregation, and the absence of recombination with two or more allelic mutants which nevertheless show recombination with one another. This lack of recombination is taken to mean that the mutant in question is caused by a multisite mutation, probably a deletion. Several of the pale-spored mutants of *Ascomobolus* are classified in Table 3 in terms of the recombination phenomena which they show. It is tentatively concluded that both secondary crossing-over and postmeiotic segregation are characteristic of multisite mutations, but that postmeiotic segregation occurs only when the extent of the mutant is short.

In attempting to explain these characteristics, multisite mutations (deletions or additions) of various sizes in bacteriophage T4 seem relevant. There is a characteristic frequency of formation of heterozygous DNA for each mutant, and this frequency is related to the length of the mutant segment in the DNA<sup>25</sup>. Drake concluded that extended mutants cannot easily be accommodated in DNA internal heterozygotes<sup>25</sup>. When they are included, they probably form single-chain loops, but with increasing length of the mutant there is a greater probability that internal heterozygotes will fail to form.

If the behaviour of DNA at meiosis is similar to that of phage T4, a short multisite mutation would be expected to give rise in some meioses to a single-chain loop when it lies within hybrid DNA, and in other meioses to prevent hybrid DNA from forming, while a long multisite mutation would regularly fail to be included in hybrid DNA. These expectations agree with the data in Table 3, because postmeiotic segregation and conversion, which are evidence of hybrid DNA formation at the mutant site, do not seem to take place (postmeiotic segregation) or only occur with low frequency (conversion) with long multisite mutations, while secondary crossing-over, which does not involve hybrid DNA at the mutant site, seems to occur with multisite mutations of all lengths.

Secondary crossing-over could therefore occur when a multisite mutation fails to enter hybrid DNA. X-rays and many other agents lead to the formation of interchanges between non-homologous chromosomes, and there is evidence that this process, and also the formation of aberrations within a single chromosome, may come about by a process analogous to normal crossing-over<sup>26,27</sup>. The non-homologous exchange process may be initiated by some event occurring independently in the two chromatids (or different parts of one)<sup>26,27</sup>. It is likely that this event is the breakage of one of the two nucleotide chains of the DNA. If a multisite mutation led to a failure of hybrid DNA formation at meiosis, nucleotide chains would be left unpaired. Possibly the presence of such single chains with free ends triggers off the process of secondary crossing-over in much the same way as is thought to happen in X-ray-induced exchanges. From evidence given here, secondary crossovers at meiosis seem to have relatively short hybrid DNA segments, occupying only a fraction of the length of a gene. If the non-homologous exchange process also depends on the formation of hybrid DNA, the hybrid segments are also likely to be short, because non-homologous chromosomes or different parts of a single chromosome would not be expected to have long segments with a nucleotide sequence in common. (Note added in proof. Berg and Curtiss<sup>30</sup> suggest that reciprocal exchange between non-homologous segments of the DNA of *Escherichia coli* to give transposition derivatives is the result of "mutual recognition" between regions of fortuitously similar nucleotide sequences. This is the same mechanism as I have proposed here to explain X-ray-induced exchanges in higher organisms.)

If secondary crossing-over is caused by multisite mutations, what is the explanation of the postmeiotic segregation which appears sometimes to be associated with it? Lacks<sup>28</sup> has found that short multisite mutations at the amylomaltase (*mal*) locus in *Diplococcus pneumoniae* show a high integration efficiency in transformation, whereas point mutations often show much lower integration efficiencies. He provides evidence that the efficiency of integration of point mutations depends on the nature of the mutation, transitions having the lowest value. Study of mutants at the aminopterin-resistance (*amiA*) locus has shown that high efficiency mutants are transmitted to daughter-cells at the third division after uptake of donor DNA and low efficiency mutants at the second division<sup>29</sup>. These are equivalent to postmeiotic segregation and conversion, respectively. At DNA replication in the recipient

Table 3. CLASSIFICATION OF SOME ASCOSPORE COLOUR MUTANTS OF *Ascomobolus immersus* TO SHOW THEIR BEHAVIOUR WHEN CROSSED WITH OTHER MEMBERS OF THE SAME SERIES, FROM THE DATA OF LISSOUBA *et al.*<sup>18</sup> AND MOUSSEAU<sup>23,24</sup>

Series	Mutant	Extent of mutant	Evidence of extent	Conversion	Postmeiotic segregation	Reciprocal recombination
Series 46	46	Single site or short multisite	No pairs of mutants known which show recombination with one another but not with one of these mutants	+	-	-
	63			+	-	-
	138			+	-	-
	277			+	+	+
Series 19 Group A	1,216	Short or intermediate multisite	Each mutant shows no recombination with a pair of mutants which nevertheless recombine with one another	+	+	+
	60			+	+	+
	1,028			(+)	-	+
	1,130			(+)	-	+
	49	Long multisite	Mutant shows no recombination with all group A mutants	(+)	-	+

+, Phenomenon given at the head of the column is shown by the mutant; -, not recorded; (+) indicates a low frequency. In assessing whether a mutant shows reciprocal recombination, the behaviour of the mutant with which it is crossed has also to be taken into account.

Fig. 2. Diagrams to illustrate possible modes of origin of six asci of *Neurospora crassa*<sup>a</sup> to show recombination within the *pan-2* locus, and crossing-over between outside markers *ad-1* and *tryp-2*. The genotypes of the four pairs of spores in each ascus are shown to the right of the corresponding diagram. The numbers 23, 72 and 36 denote the three mutant sites within *pan-2* by which the parents differed. The diploid nuclei in the young asci had the genotype  $\frac{ad-1 \ 23 \ + \ 36 \ +}{+ \ + \ 72 \ + \ tryp-2}$ . The components of the diagrams have the same meaning as in Fig. 1. Hybrid DNA can apparently enter *pan-2* from either end.

bacterium, the donor nucleotide chain could anneal with the homologous segment of the complementary chain of the recipient<sup>29</sup>. This would give a region of hybrid DNA in one of the daughter-molecules. With low efficiency mutants, an enzyme system then recognizes the mispairing in the DNA caused by the mutant, excises one chain and replaces it by a chain complementary to the other, the donor chain being excised more often than the recipient one<sup>29</sup>. If the enzyme system recognizes mismatched nucleotides in DNA, but often overlooks the lack of pairing with a multisite mutation (compare ref. 28), this would explain both the high integration efficiency and the postmeiotic segregation apparently found with short multisite mutations. The apparent absence of postmeiotic segregation with longer multisite mutants (Table 3) suggests that mutations of a sufficient length are recognized by the correcting enzyme system whenever they enter hybrid DNA, whereas short multisite mutations are not always

recognized and so can give rise to postmeiotic segregation as well as conversion.

The possible association between short multisite mutations and postmeiotic segregation could be tested by octad analysis using ascospore colour mutants of various lengths. There is no evidence that mutants 277 and 1216 in series 46 of *Ascobolus* are multisited although they show postmeiotic segregation (see Table 3), but in order to establish that a mutant occupies an extended length of the DNA it is necessary to find mutants which fail to recombine with it and yet recombine with one another. Furthermore, if a mutant was an addition of a few nucleotides rather than a deletion, it might map as a point mutation (compare ref. 25).

Some results obtained with *Neurospora crassa*<sup>8</sup> point to another possible cause of correction failure and thus of postmeiotic segregation. Thirteen asci were found in which recombination had occurred at the *pan-2* locus.

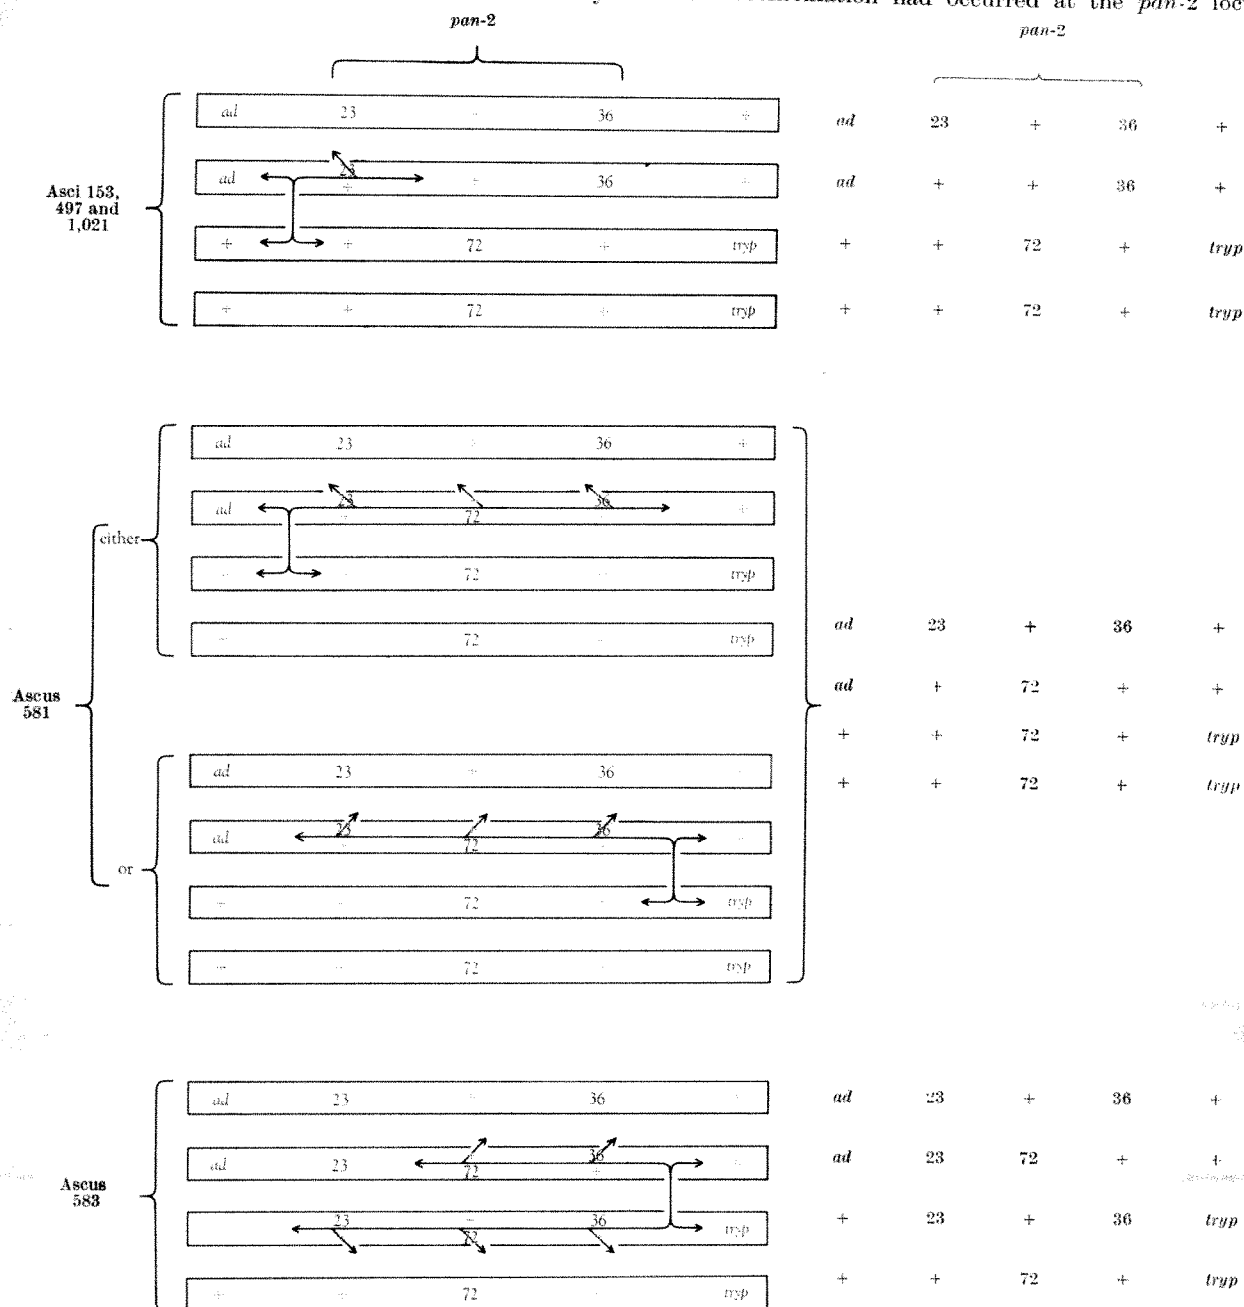

Fig. 3. Diagrams to illustrate possible modes of origin of five asci of *Neurospora crassa*<sup>8</sup> to show recombination within *pan-2*, and a parental arrangement of the outside marker genes. These asci were from the same cross as those shown in Fig. 2. The short horizontal arrows pointing away from *pan-2* indicate reverse crossovers. The other arrows have the same meaning as in Figs. 1 and 2.

Fig. 4. Diagrams to illustrate possible modes of origin of two asci of *Neurospora crassa*<sup>8</sup> to show postmeiotic segregation within *pan-2*. These asci were from the same cross as those shown in Figs. 2 and 3. The genotype of the eight spores in each ascus is shown on the right. The arrows have the same meaning as in Figs. 1-3.

The parental strains differed at three sites within this gene, and also at single sites in marker genes (*ad-1* and *tryp-2*) on each side. Eleven of the asci showed 4:4, 6:2 or 2:6 ratios of wild type: mutant genotype at the three *pan-2* sites, implying that correction of mispairing had occurred at all the sites which had entered hybrid DNA. In each of these asci, two of the four pairs of spores showed the respective parental genotypes (Figs. 2 and 3). This means that the recombination was confined in the normal way to two of the four chromatids at meiosis.

In asci Nos. 98 and 710 it is uncertain whether the hybrid DNA included site No. 23, followed by correction in opposite directions (reciprocal conversion), or whether there was secondary crossing-over. These two asci are included in Table 2. Secondary crossing-over is the more probable explanation, because the outside markers show coincident crossing-over, but both alternatives are shown in Fig. 2. Ascus No. 581, like several others in Figs. 2 and 3, provides an example of linked correction, with neighbouring sites corrected to the same parent.

Two asci have been found in which postmeiotic segregation had occurred<sup>8</sup>. It is remarkable that in both of them there was such segregation at two of the three sites, and in both asci more than two chromatids were involved in recombination either within *pan-2* or in its vicinity. The genotypes of the eight spores in these asci are given in Fig. 4 together with a likely mode of origin. It seems that in ascus No. 43 hybrid DNA from double crossovers entered *pan-2* from both ends, but one of the chromatids involved at one end was not involved at the other. In ascus No. 529 a double crossover appears to have occurred at the proximal end and a crossover involving the other two chromatids beyond the distal end.

The association, evident from these asci, between multi-stranded recombination and postmeiotic segregation would be accounted for if distortions in a DNA molecule are recognized by an enzyme moving along it and if two recombination events (either a crossover and a double crossover, or two double crossovers) in proximity to one another and involving at least three of the chromatids prevent such movement. If the two events were not quite simultaneous, the second might interfere with the movement of the enzymes over the hybrid DNA regions of the first during a critical period. This would lead to a failure of correction where the hybrid DNA from one

recombination event came close to that from the other. The position of the sites showing postmeiotic segregation agrees with this hypothesis (Fig. 4).

The idea that multistranded recombination is a cause of postmeiotic segregation could be tested by study of recombination between allelic ascospore colour mutants, preferably with outside marker genes. The use of mutants the sites of which were near opposite ends of the spore colour locus would facilitate the recognition of multi-stranded recombination when two double crossovers were involved, as in ascus No. 43 discussed here.

I am grateful to Dr S. Fogel and Dr D. D. Hurst for sending me their results in manuscript and for allowing me to refer to their work before publication. I thank Dr P. J. Hastings for valuable discussions and Mr G. J. Clark for preparing the diagrams.

# X-Ray Diffraction Study of Fossil Elemis

by

JUDITH W. FRONDEL

Department of Geological Sciences,  
Harvard University, Massachusetts

X-ray diffraction identification of  $\alpha$ -amyrin in guayaquillite, Highgate copalite and glessite places these fossil resins among the elemis in the Burseraceae family of angiosperm trees. Correlation of their geographical occurrences lends support to the belief that the so-called Amber Forests flourished during Eocene as well as Oligocene times.

RECENTLY<sup>1</sup> I suggested that there was a possible genetic relationship between the fossil resins guayaquillite and Highgate copalite and those of the modern genera *Protium* and *Bursera* in the Burseraceae family of angiosperm trees. This relationship was postulated on the basis of the similarity of their X-ray diffraction patterns, and the technique for obtaining these patterns was described. More recently the constituent represented by these patterns has been identified as  $\alpha$ -amyrin, a principal component of the elemis.

Elemi is the group name for the fragrant resin of several angiosperm trees of different botanical origins. According to Wehmer<sup>2</sup> this origin is not always certain, but Tschirch<sup>3</sup> assigned the elemis to various genera of the Burseraceae family, primarily *Canarium* and *Protium*. Some elemis come also from several species of *Amyris* and *Bursera*, and Tschirch classed the genus *Amyris*, in part, with the genus *Protium*. Elemis consist essentially of amyirin, resin acids, resenes and volatile oils and, in the narrowest sense, the true elemis are only those resins which contain crystalline amyirins. These are triterpenoid alcohols— $C_{30}H_{50}O$  (refs. 3 and 4). Both  $\alpha$ - and  $\beta$ -amyrin exist together in the resins, but the  $\alpha$ -amyrin is the predominant form. The amyrin was usually detected by its characteristic needle like crystals seen under the polarizing microscope, and chemical extraction followed by a melting point determination. In this investigation, the chemical extraction was not necessary as the high percentage of amyrin present, generally between 20–30 per cent, permitted its detection and identification in the resins by X-ray diffraction. Using pure  $\alpha$ -amyrin as a standard, I have identified it in a number of modern elemis, among which are: Yucatan copal from *Amyris elemifera*<sup>5</sup> or *Amyris plumieri*<sup>5</sup>; South American Tacamahaca resin from *Protium heptaphyllum*<sup>5</sup>; Brazilian elemi from *Protium icicariba* or *Protium heptaphyllum*<sup>6</sup>; and resin from *Bursera bipinnata*. Their X-ray diffraction patterns are shown in Fig. 1 and the  $d$ -spacings are given in Table 1.

The fossil resin guayaquillite from Ecuador is found in deposits of undetermined geological age. Johnston<sup>7,8</sup>, who first described it, suggested that it was of vegetable origin because, like amber, it occurred on the site of ancient forests of resiniferous trees. The X-ray diffraction pattern of guayaquillite (Fig. 1 and Table 1) shows the presence of  $\alpha$ -amyrin. Hence, it can be classed with the elemis.

Johnston<sup>9</sup> also described the Highgate resin or copalite which was found in the London Blue Clay of Eocene age. He compared this resin, on the basis of chemical analyses, with the anime-resin of a "Locust-tree" (Leguminosae) in French Guiana, South America. This was a false comparison, for, although the anime-resin comes from *Hymenaea courbaril*, a Leguminosae, the X-ray diffraction pattern of the Highgate copalite (Fig. 1 and Table 1), revealing the presence of  $\alpha$ -amyrin, indicates that it is an elemi. Reid and Chandler<sup>10</sup> mentioned fossil plant remains of various genera of the Burseraceae family found in the London Clay. The suggestion by Langenheim<sup>11</sup> that these plant remains present a possible botanical source for the Highgate copalite is now validated.

$\alpha$ -Amyrin was identified in still another fossil resin, the rare glessite (Fig. 1 and Table 1), found in the "Blue Earth" of the east Baltic along with Baltic amber. Although Paclt<sup>12</sup> classes glessite together with the Baltic ambers from coniferous trees, Helm<sup>13</sup>, who named and first described the material, claimed that under the microscope it showed a resemblance to modern Myrrh in the Bur-

# Formation of Sparks by Several Electron Avalanches

by  
ALFRED FROHLICH

Department of Physics,  
Tel Aviv University,  
Israel

In a spark chamber, interaction between electron avalanches causes the resultant spark to incline along the particle track. At an angle of incidence greater than about  $35^\circ$  the sparks tend to follow the electric field.

THE formation and the appearance of sparks produced by the avalanche and streaming of a single electron have been extensively investigated<sup>1,2</sup>. A streamer originating from a single electron avalanche can propagate over long distances, even where the initial ionization is negligible; lightning discharges are an example<sup>3</sup>. In a spark chamber the ionization extends initially along the path of the triggering event and the spark, which is eventually visible, may be the result of several electron avalanches developing simultaneously. When these avalanches interact, sparks are inclined away from the direction of the applied field in a spark chamber. This article describes an extension of the existing theory including the effects of multiple electron avalanches.

According to the Meek criterion, a streamer begins when the field due to the intrinsic space charge inside the avalanche equals the electric field immediately outside it. The electric field is the vector sum of the field applied between the electrodes of the spark chamber,  $E_a$ , and the fields between adjacent avalanches,  $E_s$  (see Fig. 1). The most probable direction of the streamer and of the visible spark is determined by the direction of this field at the onset of the streamer.

The fields, at the head of one avalanche due to the negative charges located at the centres of adjacent electron

clouds, cancel if it is assumed that all of the avalanches grow at the same rate, the quantities of charge in each are equal, the avalanches are equally spaced, and the centres of each avalanche are aligned with each other. This cancellation does not occur near the end of the line of avalanches, and this can occasionally be observed near the electrodes as distortions in the line of the sparks<sup>4</sup>. It will be assumed that the effective centre of the positive charges, caused by ionization, is at the centre of each avalanche.

It has been shown<sup>2</sup> that the radius of the electron cloud at the head of an avalanche, at any moment up to the onset of the photo-ionization, is given by the distance diffused by an electron within the time interval from the start of the pulsed electric field. The forces due to the mutual repulsion of the electron space charge become appreciable only when the streamers propagate.

At any time  $t$ , therefore, the internal field of an avalanche is

$$E_i = \frac{nq}{4\pi\epsilon_0} (2D_i) \frac{V}{m}$$

where  $q$  is the charge of an electron and  $D$  is the thermal diffusion coefficient<sup>5</sup>.

Similarly, in the notation of Fig. 1, the space charge field is

$$E_s = \frac{nq}{4\pi\epsilon_0} \sum_{i=1}^2 \sum_{j=1}^m \frac{1}{(R_{ij})^3} R_{ij} \frac{V}{m}$$

where  $m$  is the number of effective avalanches on either side of the one under consideration. In these calculations  $m$  was taken to equal 5; larger values did not appreciably affect the results.

The angle of incidence of the resultant field, with respect to the applied field, at the moment when the Meek criterion predicted the onset of streamers is shown in Fig. 2. They are plotted as functions of the angle of incidence of the original ionized track and of the mean avalanche spacing. The angles connecting the inclinations of the resultant field vary when there is a variation of  $\pm 0.5$  nsec in the development time of the avalanche. It was assumed that the applied field increased linearly with time. It can be seen that as the avalanches come closer together, for example with an increase in the gas pressure, the sparks follow the particle track more faithfully. The mean spacing of the avalanches in an experimental gas mixture at atmospheric pressure was found to be between 0.4 mm and 0.5 mm (ref. 6).

Fig. 3 shows how the theoretical maximum inclination of the sparks and their formation times vary with the applied pulse parameters for an avalanche spacing of 0.4 mm. Fig. 4 compares the theoretical predictions with the experimental results for the sparks, in a 1 in. gap spark chamber, which were triggered by relativistic muons. As the angle of incidence increased beyond about  $35^\circ$  the space charge fields on either side of the avalanche tended to cancel each other out, so that the sparks tended to follow the direction of the applied field rather than the track of the muon.

Fig. 1. Spark model.

The theoretical predictions here agree with experimental results reviewed elsewhere<sup>7,8</sup>. They all show the sparks following the particle track up to a maximum angle of incidence between 25°–35°, and thereafter following the applied field, although occasional sparks were inclined at larger angles. Because the space charge interaction is small at these large angles, the electron avalanches and streamers can develop individually and many closely spaced sparks can often be seen in the gap traversed by the particle.

The interaction between electron avalanches can be seen clearly when the resultant fields, acting at the head of each avalanche, are not aligned. If the subsequent streamers develop together and the misalignment is small the sparks may appear in steps or kinks<sup>9</sup>.

As can be seen from Fig. 2, fluctuations in the inclinations of the sparks could occur because of variations in the avalanche spacing and because of variations in the development time of each avalanche. These inherent angular fluctuations set an upper limit to the accuracy with which a particle track may be fitted to the sparks<sup>6</sup>.

The fluctuations can originate in two ways: first, the ionization density left by a relativistic particle follows a normal distribution, and small statistical variations in the spacings of the ions and of the electrons are very

Fig. 2. Theoretical spark inclinations. Applied pulse, 1 kV/cm/nsec. Avalanche spacing: top, 0.3 mm; middle, 0.4 mm; bottom, 0.5 mm.

Fig. 3. Effects of the parameters of the applied field. Avalanche spacing of 0.4 mm.

Fig. 4. Theoretical angular deviations of the sparks from the track.  $\times$ — $\times$ , Theoretical;  $\circ$ — $\circ$ , experimental values for 1 in. gaps.

probable<sup>10</sup>; second, at the onset of the streamers the rate of increase of the space charge fields is very large, and small variations in the spacing and in the development time have a marked effect on the relative delays between the propagation of the streamers from individual avalanches. These effects are magnified by the addition of alcohol vapours to the gas mixture. It has been shown that the addition of about 2 per cent of ethyl alcohol to a 90 per cent neon + 10 per cent helium gas mixture can increase the brightness and linearity of the sparks<sup>11</sup>.

As soon as one streamer develops it rapidly propagates along the direction of the resultant field at each point. The resultant ionization distorts the electric field around the avalanches so that they are absorbed or suppressed in their development. The luminous modulation along a spark, especially when the spark development has been curtailed<sup>8</sup>, corresponds to the regions of maximum ionization, one for each streamer. This is very noticeable in wide gaps operating with very short pulsed fields.

Up to the moment of writing no quantitative model of the propagation of streamers has been published. It is a stochastic process and would involve successive photo-ionization along the continually enhanced electric field, produced by the previous ionization and by the presence of the neighbouring avalanches. The most probable path of the streamers among the fluctuations of the space charge fields and the continuously varying successive photo-ionization might be evaluated by the Monte Carlo method.

I thank Dr P. T. Trent of Birkbeck College, London, for many fruitful discussions, and the Science Research Council for a grant.

## ASTRONOMY

### Radio Source Spectra and the Cosmological Red-shift

RECENT spectral surveys of discrete radio sources have not revealed any significant dependence of spectral index on apparent intensity<sup>1-3</sup>. It is therefore of interest to determine the way in which the mean observed spectral index depends on flux density, when the effects of cosmological red-shift are taken into account. We shall choose, by way of example, a hyperbolic world model.

The observed flux density  $S(\nu)$  at a frequency  $\nu$ , from an isotropic source of emission of intrinsic luminosity  $P(\nu_e)$ , at a frequency  $\nu_e$ , in unit bandwidth over  $4\pi$  steradians, if red-shifted by  $z$  and located  $\omega$  from the observer in co-ordinate space, is given by

$$S(\nu) = \frac{P[\nu(1+z)]}{R_0^2(1+z) \sinh^2 \omega} \quad (1)$$

where  $\nu_e = \nu(1+z)$ ,  $R_0$  is the scaling factor in the Robertson-Walker metric equation

$$ds^2 = dt^2 - \frac{R^2(t)}{c^2} \{d\omega^2 + J^2(\omega)(d\theta^2 + \sin^2\theta d\varphi^2)\}$$

$R_0$  being evaluated at time  $t=t_0$  and

$$\omega = \frac{cT_0}{R_0} \int_0^z \frac{dz}{\{1+2(q_0+1)z+(q_0+1+3\sigma_0)z^2+2\sigma_0 z^3\}^{1/2}} \quad (2)$$

(see ref. 4). Let the number of sources,  $n$ , be in a unit co-ordinate volume independent of  $t$ , and the probability that a radio source has a spectral behaviour of the form  $P(\nu_e)z\nu_e^{-\alpha}$ , be  $p(\alpha)\delta\alpha$  in the range  $\alpha \pm \delta\alpha/2$ . The physical volume contained by a spherical shell of co-ordinate thickness  $\delta\omega$  and radius  $\omega$  is

$$4\pi R^2 \sinh^2 \omega \delta\omega$$

Thus the number of sources observed between  $\check{\omega}$  and  $\hat{\omega}$  having spectral indices  $\alpha \pm \delta\alpha/2$  is

$$\begin{aligned} & 4\pi n_0 \int_{\check{\omega}}^{\hat{\omega}} R_0 \sinh^2 \omega d\omega p(\alpha) \delta\alpha \\ &= 4\pi n_0 R_0^3 \left[ \frac{\sinh^2 \omega}{4} - \frac{\omega}{2} \right]_{\check{\omega}}^{\hat{\omega}} p(\alpha) \delta\alpha \end{aligned}$$

The values of  $\check{\omega}$  and  $\hat{\omega}$  are defined in terms of the observable flux density by equation (1), that is to say, if it is asked how many sources are observed to have a flux density between  $\check{S}$  and  $\hat{S}$  and a spectral index  $\alpha \pm \delta\alpha/2$  which have an intrinsic power  $P_0$  at a reference frequency  $\nu_0$  and dependence on frequency of the form  $\nu_0^{-\alpha}$ , then  $\check{\omega}$ , say, is defined by the equation

$$\check{S}(\nu) = \frac{P_0 \left( \frac{\nu}{\nu_0} \right)^{-\alpha} (1+z)^{-\alpha-1} (q_0+1-3\sigma_0)}{c^2 T_0^2 \sinh^2 \check{\omega}} \quad (3)$$

that is, in terms of  $T_0$ ,  $q_0$  and  $\sigma_0$ —the Hubble time, acceleration and density parameters, respectively<sup>4</sup>. Thus, the observed distribution of spectral indices in a flux density range  $\check{S}$  to  $\hat{S}$ , conditional on the parameters of the cosmology  $T_0$ ,  $q_0$ ,  $\sigma_0$ , and on the nature of the radio sources  $P_0$  and spectral distribution in co-ordinate space defined by  $p(\alpha|\check{\alpha}, \check{\sigma})$ , is, explicitly

$$F(\alpha|T_0, q_0, \sigma_0; \check{\alpha}, \check{\sigma}; \check{S}, \hat{S}) \delta\alpha$$

is proportional to

$$p(\alpha|\check{\alpha}, \check{\sigma}) \delta\alpha \left[ \frac{\sinh^2 \omega}{4} - \frac{\omega}{2} \right]_{\check{\omega}}^{\hat{\omega}} \quad (4)$$

where the probability distribution  $p(\alpha|\check{\alpha}, \check{\sigma})$  is characterized by a mean spectral index  $\check{\alpha}$  and spread  $\check{\sigma}$ . Clearly, then, the last term in equation (4) will modify the observed distribution of  $\alpha$  because of the functional dependence of  $\omega$  on  $\alpha$ —equation (3).

It is intuitively clear that in an expanding universe only sources with the flatter spectra (low  $\alpha$ ) will survive the red-shift effect in a given range of flux densities. Thus we might expect a shift in the mean observed spectral index,  $\check{\alpha}_0$ , say, in the sense that  $\check{\alpha}_0 < \check{\alpha}$ .

Let us consider by way of example<sup>4</sup>

$$\begin{aligned} 3 &\geq q_0 \geq 1 \\ 0.2 &\geq \sigma_0 \geq 0 \end{aligned}$$

$$h_1 = 100 \text{ km/sec/Mpc} = 1/T_0 \text{ (following ref. 5)}$$

$$\check{\alpha} = 0.75$$

$$\check{\sigma} = 0.20$$

$$(p(\alpha|\check{\alpha}, \check{\sigma}) \alpha \exp \left\{ -\frac{1}{2} \left( \frac{\alpha - \check{\alpha}}{\check{\sigma}} \right)^2 \right\})$$

The effects on the observed distribution of spectral indices of changes in  $P_0$ ,  $\sigma_0$  and  $q_0$  will now be investigated.

By numerical procedures, various of these equations necessary for the evaluation of  $\check{\alpha}_0$  were solved using an Atlas computer. The results for  $q_0 = 1.8$  and  $\sigma_0 = 0.2$  may be seen in Fig. 1. As expected,  $\check{\alpha}_0$  tends to decrease as the level of flux density is lowered: the higher the intrinsic luminosity ( $P_0$ , defined at 178 Mc/s), the more severe the effect of observational selection. For  $P_0 = 8 \times 10^{25} \text{ W (c/s)}^{-1} \text{ sterad}^{-1}$ ,  $\check{\alpha}_0$  deviates from  $\check{\alpha}$  by only 0.02 at  $S_{178}^* = 1.0$ ; for luminosities an order of magnitude higher:  $\check{\alpha} - \check{\alpha}_0 = 0.03$  at  $S_{178} = 2.0$ .

Altering  $q_0$  and  $\sigma_0$  within the ranges given here does not change  $\check{\alpha}_0$  by more than 0.005. No combination of  $q_0$  and  $\sigma_0$  makes the observed dispersion of spectral indices significantly different from  $\check{\sigma} = 0.20$ .

Fig. 1. Effect of observational selection on the mean observed spectral index. Model:  $q_0 = +1.8$ ;  $\sigma_0 = +0.2$ ;  $\check{\alpha} = 0.75$ ;  $\check{\sigma} = 0.20$ . a,  $P_0$  ( $\text{W(c/s)}^{-1} \text{ sterad}^{-1}$ ); b,  $P_0 = 8 \times 10^{27}$ ; c,  $P_0 = 8 \times 10^{26}$ ; d,  $P_0 = 8 \times 10^{25}$ ; e,  $P_0 = 8 \times 10^{24}$ ; f,  $P_0 = 8 \times 10^{23}$ .

It has been shown that for a range of feasible model universes uniformly populated with radio sources which have spectra of the form  $\nu^{-\alpha}$ , observational selection discriminates against high spectral indices.

Sources included in the 178 Mc/s spectral surveys<sup>1-3</sup> probably lie chiefly in the luminosity range  $8 \times 10^{24} < P_0 < 8 \times 10^{26} \text{ W m}^{-2} \text{ (c/s)}^{-1} \text{ sterad}^{-1}$ . No correlation has been observed between  $S_{178}$  and  $\check{\alpha}_0$ . The theoretical average value of  $\check{\alpha} - \check{\alpha}_0$  at  $S_{178} = 2.0$  is approximately 0.01, because of the selection effects discussed here, but no account has been taken of spectral curvature. This value of 0.01 is of the same order as the experimental uncertainty in  $\check{\alpha}_0$ ; the calculations given here are therefore consistent with the observations.

\*  $S_{178}$  in units of  $10^{-26} \text{ W m}^{-2} \text{ (c/s)}^{-1}$ .

A spectral survey of discrete sources down to about  $S_{178}=0.1$  may reveal quite significant changes in the average apparent spectral index. The direction of this change, however, will depend on the relative effects of spectral curvature, source evolution and distribution, together with geometry.

### Relative Intensities of Hydrogen Recombination Lines in Gaseous Nebulae

RECENTLY, Gardner and McGee<sup>1</sup> have published measurements on the  $126\alpha$ ,  $159\beta$  and  $158\beta$  recombination lines of hydrogen in two galactic nebulae. These lines have frequencies differing by less than 2 per cent and are therefore observed with the same beamwidth. Their results are summarized in Table 1.  $T_L$  is the measured peak line temperature above the continuum.  $(T_{L\beta}/T_{La})_E$  is the predicted ratio of temperatures assuming thermodynamic equilibrium and equal line widths.

The effect of departures from thermodynamic equilibrium has been pointed out by Goldberg<sup>2</sup>. The solution of the transfer equation under these circumstances is

$$T_L = b_n \left( 1 + \frac{\gamma}{2} \tau_C \right) T'_L \quad (1)$$

where  $\tau_C$  is the optical depth in the continuum;  $\gamma = (kT_e/h\nu) (d \ln b_n/dn) \Delta n$ ;  $T'_L$  is the line temperature in thermodynamic equilibrium.  $\Delta n$  is 1 or 2 for an  $\alpha$  and  $\beta$  transition, respectively. Equation (1) is derived assuming that the optical depth in the line and the continuum is small. From equation (1), the ratio of the line temperature ratio out of thermodynamic equilibrium to that in thermodynamic equilibrium is simply

$$R = \frac{(T_{L\beta}/T_{La})}{(T_{L\beta}/T_{La})_E} = \frac{b_{n\beta} \left( 1 + \frac{\gamma_\beta}{2} \tau_C \right)}{b_{n\alpha} \left( 1 + \frac{\gamma_\alpha}{2} \tau_C \right)} \quad (2)$$

I have calculated values of  $R$  for  $T_e = 10^4$  °K from computations of  $(d \ln b_n/dn)$  as a function of electron density.  $\tau_C$  is calculated from<sup>3</sup>

$$\tau_C = 8.24 \times 10^{-2} T_e^{-1.35} \left[ \frac{\nu}{G \text{ c/s}} \right]^{-2.1} \left[ \frac{E}{\text{pc.cm}^{-6}} \right] \quad (3)$$

$E$  is the emission measure. In Fig. 1,  $R$  is shown as a function of emission measure for various densities. Also shown are the measured ratios and their uncertainties from Table 1. The emission measures for the two nebulae are taken from Mezger and Henderson<sup>3</sup>. The root-mean-square electron density of M17 is  $565 \text{ cm}^{-3}$  (ref. 3), and of the Orion Nebula is  $\geq 10^3 \text{ cm}^{-3}$  (ref. 4).  $R$  does not depend much on density for densities  $\geq 10^2 \text{ cm}^{-3}$ . The measured ratios are in only approximate agreement with the theory, but definitely show a trend to the occurrence of maser

Fig. 1.  $R$  as a function of emission measure for various densities. The arrows give the emission measures of the two nebulae.

action. Computed values of  $R$  are about 10 per cent outside the uncertainty range for the Orion Nebula. This could be accounted for by broadening of the  $n=158$  quantum level. So far, however, there has been no definite detection of broadening in the higher quantum levels.

It is evident that a series of measurements of  $\alpha$  and  $\beta$  transitions of approximately the same frequency would be of great value in confirming the maser action. For the two lines discussed in this paper, regions of local density  $\sim 10 \text{ cm}^{-3}$  or  $\sim 10^3 \text{ cm}^{-3}$  would provide the optimum conditions in the sense of greatest deviation of  $R$  from unity.

## PLANETARY SCIENCE

### Radius of the Earth's Core

ACCORDING to the modified Lomnitz law of imperfect elasticity, the response to a constant stress contains a term in  $t\alpha$ . I have pointed out<sup>1</sup> that in a vibration, according to this law, besides the damping of vibrations, there is a delay proportional to  $(\text{period})^\alpha$ ; this would be small for the  $S$  waves that I was considering. If, however,  $1/Q$  is the damping factor as usually defined, the delay lengthens the period by a factor  $(1/Q) \cot \frac{1}{2}\pi\alpha$ . For the slowest free vibration of the Earth as a whole  $Q$  appears to be about 400; with  $\alpha = \frac{1}{2}$ , as I have suggested, the factor would be about  $1/160$ .

Theoretical periods of free vibrations are systematically of the order of 1 per cent shorter than the observed ones. Suggested explanations have been a surprising constancy of density in the lower part of the shell<sup>2</sup> and an increase of about 15 km in the radius of the core<sup>3</sup>. It seems that my suggestion may provide an alternative.

I have analysed the observations of  $PcP$  (longitudinal waves reflected at the core boundary) given by Buchbinder<sup>4</sup> and find that they indicate an increase of the core radius by  $3 \pm 5$  km. Thus they would be consistent with my 1940 solution, the apparent standard error of

Table 1. OBSERVED AND PREDICTED TEMPERATURE RATIOS

Nebula	$T_{L\beta}/T_{La}$	$(T_{L\beta}/T_{La})_E$
Orion	$0.13 \pm 0.03$	0.224
M17	$0.22 \pm 0.04$	

which was 3.5 km, and rather against an increase by 10 km.

## Age of the Irish Sea Glaciation of the Midlands

THE red till (or tills) with erratics from the Lake District and south-west Scotland, found in Lancashire, Cheshire, Staffordshire and Shropshire, has been ascribed to what has been called the Irish Sea Glaciation. That more than one ice advance could be represented by similar material has long been recognized, but the southward limit of the Lake District and Scottish boulders lay along a line Church Stretton-Wolverhampton-Burton on Trent, and this "Wolverhampton Line" could be taken as the southernmost extension of the Irish Sea Glacier<sup>1</sup>. The date of this advance has been variously claimed to be Late-Würm, Early-Würm and Riss (Saale). I have ascribed it to the Early-Würm<sup>2,3</sup> and accepted the view of Boulton and Worsley<sup>4</sup> that the Wrexham-Barr Hill Moraine was the most southerly extension of the Late-Würm glaciation as corroboration of this. Now, as the result of work here—stratigraphy by Mr A. V. Morgan, palaeontology by Dr G. R. Coope and radiocarbon dating by Mr R. E. G. Williams—it can be demonstrated that the advance of the Irish Sea Glacier to the Wolverhampton Line occurred in Late-Würm times, that is, it probably centred around a date of about 25,000 yr ago.

In the region of Four Ashes (*SJ* 9208) about 5 miles north of Wolverhampton and thus north of the Wolverhampton Line but well south of the Wrexham-Barr Hill Line, sheet 153 of the Institute of Geological Sciences shows an extensive cover of boulder clay. This is typical Irish Sea till with characteristic erratics, often very large. The map does not reveal the existence beneath this till of a great spread of water-deposited gravels and sands now worked commercially on a large scale. Working faces change rapidly but there is always a three-fold succession, in descending sequence, of till (from as little as 1 to as much as 8 ft. thick) on gravel and sand (4–15 ft. thick) on Upper Bunter Sandstone. The till undoubtedly overlaps the gravel and rests directly on the Bunter beyond the area of gravel working. Nowhere have we seen a till beneath the gravels, but it is significant that the latter, although almost entirely derived from Bunter Pebble Beds, contain rare pebbles of rhyolites, rhyolitic ashes and andesites, and also brown flints testifying to the presence, somewhere to the north, of an earlier source of Irish Sea material.

Interbedded with the gravels are layers of organic silt and peat, at the base in hollows on the Bunter Sandstone, and at various levels within the body of the gravels. Two peaty samples, taken from different layers within the gravels, have been dated at the Radiocarbon Laboratory here with the following results

Birm. 24    36,340 ± 770 years B.P.  
                  — 700

Birm. 25    30,655 ± 765 years B.P.  
                  — 700

These dates indicate that the gravels belong to the Mid-Würm or Upton Warren Interstadial<sup>3,5</sup>, a conclusion which I believe Dr Coope would have maintained in the absence of any dates, from a comparison of the large insect fauna from the organically rich layers with that from other

known sites of this interstadial. It therefore follows that the overlying till must be Late-Würm in age.

## Nannofossils in Eocene Eugeosynclinal Limestones, Olympic Peninsula, Washington

LIMESTONE lenses occur within a thick sequence of Eocene volcanic rocks (known as the Crescent or Metehosin Formation) that border the northern, eastern and southern sides of the Olympic Peninsula in north-western Washington State. These carbonate rocks have previously been thought to have a largely inorganic origin<sup>1</sup>, but electron microscopy, which I report here, indicates the presence of abundant nannofossils and suggests a different origin.

The volcanic rocks are predominantly basalts, apparently principally the products of submarine eruptions, and they occur as pillow-lavas, flows, breccias and tuffs. Associated with them are discontinuous layers of argillite and hard, most commonly red to pink, and locally manganeseiferous limestone. Limestone bodies appear to be lensoid, between a few inches and 200 ft. thick, and with lateral dimensions from a few tens of feet to more than 2 miles. These bodies usually lie between volcanic layers, but limestone sometimes occurs within cores of basalt pillows or forms a matrix enclosing pillows. Limestone is also present as angular fragments in volcanic breccias and as xenolith like inclusions in basalt flows.

These close spatial associations of limestones and volcanics led Park<sup>1</sup> to propose a direct relationship between submarine volcanism and limestone genesis. Referring to an earlier hypothesis of Kania<sup>2</sup>, he suggested that agitation and heating of sea water above sites of submarine eruptions led to local inorganic precipitation of calcium carbonate, a process which was perhaps enhanced by release of calcium during early spilitization of the volcanic rocks.

As seen in thin sections, many of the limestones comprise 5–15 per cent planktonic Foraminifera embedded in a fine-grained calcitic matrix. This matrix also contains a few dispersed coccospheres and pentoliths of the nannofossil genus *Braarudosphaera*, as well as tiny spherical shells which can be assigned to the coccolithophorid genus *Thoracosphaera*<sup>3</sup>. The remainder of the predominant matrix appears in thin sections and at high optical magnifications as a largely unresolvable mixture of abundant small calcite grains and smaller amounts of non-carbonate grains such as clay minerals, iron oxides, and secondary, microcrystalline quartz.

Electron microscopy confirms the presence of nannofossils and indicates that they are far more numerous than would be suspected from examination of thin sections alone. Ten limestone specimens from widely separated parts of the Olympic Peninsula were studied with the electron microscope using the two-stage peel-replica method of sample preparation<sup>4</sup>. Coccoliths and fragments of coccoliths (Fig. 1) are the most abundant form observed. Other common nannofossils are *Thoracosphaera* shells (Fig. 1a, left), *Braarudosphaera* pentoliths and discoasters (Fig. 1b). These forms are further illustrated by Fischer, Honjo and Garrison<sup>5</sup>. All of the specimens investigated contain abundant nannofossils, and the matrix in many comprises up to 60 per cent nannofossils with abundances of 3–4 × 10<sup>6</sup>/mm<sup>3</sup> of limestone. In some

specimens recrystallization has partially destroyed many nannofossils, as is evident in Fig. 1a where the coccolith in the upper centre area is partly replaced.

The present work does not exclude the possibility that some of the calcite in the limestone specimens investigated was a primary inorganic precipitate. The observations so far, however, suggest that the limestones studied were pelagic oozes, composed chiefly of nannoplankton and planktonic foraminifers, and comparable with modern globigerinid oozes. Such oozes may have slowly accumulated on top of a submerged volcanic terrain during periods of volcanic quiescence. Subsequent, renewed volcanism apparently tended to disrupt the carbonate layers, incorporating them as matrix between pillows or as fragments within breccias and flows, and leaving only lensoid remnants of the original deposits.

## THE SOLID STATE

### High Pressure Transformations in Zinc Germanates and Silicates

THIS communication reports some observations of the behaviour of some zinc silicates and germanates at high pressures. The compounds investigated were  $\text{Zn}_2\text{SiO}_4$ ,  $\text{Zn}_2\text{GeO}_4$ , together with mixtures of pyroxene compositions— $\text{ZnGeO}_3$  and  $\text{ZnSiO}_3$ . The results are of a preliminary nature, and the principal objective of this communication is to record the occurrence of transformations in these compounds, and where possible to indicate the nature of these transformations.

The compounds  $\text{Zn}_2\text{GeO}_4$  and  $\text{Zn}_2\text{SiO}_4$  were prepared by intimately mixing the constituent oxides in the requisite proportions, pelletizing, and heating for 2–3 h at temperatures between 50° and 200° C below the respective solidus temperatures. After heat treatment, the tablets were crushed and checked for homogeneity by X-ray diffraction and microscopical examination in immersion liquids. If not homogeneous, the powders were remixed, pelletized and reheated. This procedure sufficed to produce homogeneous single phases. The runs on  $\text{ZnSiO}_3$  and  $\text{ZnGeO}_3$  compositions were carried out on unfired mixtures of ZnO with silicic acid and hydrous germania, respectively.

Samples so prepared were subjected to controlled high pressure-temperature conditions in two types of apparatus. The first was a piston-cylinder apparatus as described before<sup>1,2</sup>. All samples were subjected initially to a pressure of 35 kbar at 1,100° C for 2 h. If transformations were observed, the samples were run at successively lower pressures, but with the same temperature/time conditions. All samples were also subjected to desired pressures in the range 60–150 kbar at 900°  $\pm$  200° C for 5 min in a Bridgman anvil apparatus equipped with an internal heater<sup>3</sup>. After completion of runs, the samples were quenched under pressure, removed from the apparatus and examined by microscopic and X-ray diffraction methods. The following results were obtained.

For  $\text{Zn}_2\text{GeO}_4$ , which has the phenacite structure at atmospheric pressure there was no change at a pressure of 10 kbar, 1,100° C; however, at pressures of 20 kbar and 35 kbar (1,100° C) and at 110 kbar (900° C) it transformed completely to a slightly distorted spinel structure (pseudocubic lattice parameter 8.3 Å).

According to Hayashi *et al.*<sup>4,5</sup>  $\text{Zn}_2\text{SiO}_4$  (willemite), which also has the phenacite structure at atmospheric pressure, transforms to an olivine structure at 1,500° C and 42 kbar. We did not observe a transformation at 35 kbar, 1,100° C, but at 110 and 130 kbar, 900° C, there was complete transformation into a denser, birefringent phase. The maximum and minimum refractive indices of this phase were 1.75 and 1.77 ( $\pm$  0.005). The principal lattice spacings are given in Table 1. This phase may be

an olivine, but the resemblance of the X-ray diffraction pattern to those of other olivines is not striking. A further run was carried out on  $\text{Zn}_2\text{SiO}_4$  at a higher pressure—150 kbar. Complete transformation into an even denser birefringent phase with a mean refractive index of about 1.87 was observed. From the difference of refractive indices, this phase is estimated to be about 23 per cent denser than willemite. The X-ray diffraction pattern is complex—the spacings of the principal reflexions are given in Table 1.

A mixture of  $\text{ZnO}$  and  $\text{SiO}_2$  in equimolar proportions crystallizes at one atmosphere to  $\text{Zn}_2\text{SiO}_4$  (willemite) +  $\text{SiO}_2$ , but at 30 kbar at 500° C. Hayashi *et al.*<sup>4,5</sup> reported that the mixture crystallizes to a pyroxene structure. We have confirmed this synthesis. At 35 kbar, 1,100° C, and at 120 kbar, 900° C, the mixture crystallized to a pyroxene like structure.

An oxide mixture of  $\text{ZnGeO}_3$  crystallizes at one atmosphere to  $\text{Zn}_2\text{GeO}_4$  (phenacite structure) +  $\text{GeO}_2$ . This was also found to be the stable assemblage at 10 kbar, 1,100° C, but at 20 kbar, 35 kbar (1,100° C) the mixture crystallized to  $\text{Zn}_2\text{GeO}_4$  (spinel structure) +  $\text{GeO}_2$  (rutile structure). A further transformation was found in the 110 kbar, 900° C run. The  $\text{ZnGeO}_3$  composition was found to crystallize completely to an ilmenite structure, similar to the high pressure modifications of  $\text{MgGeO}_3$  and  $\text{MnGeO}_3$ . Thus, in this case, we have the reaction

occurring with increase of pressure from 35 kbar to 110 kbar.

These results contribute towards a broader understanding of the behaviour at high pressures of  $\text{M}(\text{SiGe})\text{O}_3$  and  $\text{M}_2(\text{SiGe})\text{O}_4$  compounds ( $\text{M} = \text{Mg}, \text{Fe}, \text{Ni}, \text{Co}, \text{Mn}, \text{Ca}, \text{Cd}, \text{Zn}$ ) which have formed the subject of many previous investigations in this laboratory<sup>6</sup>. Nearly all these compounds which have been investigated so far display major phase transformations at high pressures. A systematic understanding of these transformations has important applications to studies of the constitution of the Earth's mantle.

## PHYSICS

### Aging and Degradation in Dilute Polymer Solutions

WE have studied the properties of dilute solutions of polymers which have been found to reduce friction in turbulent flows<sup>1</sup>. The substances tested, in solution in tap water, were guar gum, polyethylene oxide (Union Carbide 'Polyox' WSR 301) and polyacrylamide (Dow 'Separan' AP 30). It had been previously found that solutions of 'Polyox' and 'Separan' exhibit normal-stress difference effects<sup>2</sup>. Correspondingly for 'Polyox' solutions, it has been reported<sup>3</sup> that the pressure increment at the mouth of a pitot tube, or open-ended tube facing into the flow, can be reduced below the value  $\frac{1}{2}\rho V^2$  normal for Newtonian liquids, where  $\rho$  is density and  $V$  is speed. The present experiments began as a further investigation of this loss of pitot pressure. It was found that the pitot loss reduced with time, and that with 'Polyox' solutions other normal-stress difference effects showed a similar aging, without apparently impairing the ability of the liquid to produce turbulent drag reduction. Continued exposure of the liquid to intense turbulence does, however, lead to a degradation of the drag reduction.

The apparatus used was as in Fig. 1. Liquid in a header tank *H* could have an air pressure *p*, positive or negative relative to the atmosphere, applied to its upper surface. The liquid descended through a nozzle *N* and emerged through a smoothly rounded orifice *O*, of 2.5 mm narrowest diameter, to form a jet, which flowed over a pitot tube, of 0.9 mm outside diameter, and then into a receiver tank *R*, from which the fluid was returned by a peristaltic pump to the header tank. The liquid pressure in the header tank was observed in an open-ended manometer tube, in which the liquid level rose, of course, by an amount *p* above the level in the header tank. The level to which the liquid rose in a manometer tube attached to the pitot enabled the pitot loss *L* to be determined as a fraction of the true pitot pressure *P*.

Typical results are shown in Figs. 2 and 3. In Fig. 2 results for two solutions of 'Polyox', both of 70 p.p.m. concentration, are shown. One was tested 4 days after mixing, and the other within 3 h of mixing. Pitot loss is shown as a fraction of time after starting up the flow in the apparatus, with *P* held constant at 34 cm ( $V = 260$  cm/sec in the jet at the pitot mouth). The liquid level in the pitot manometer tube was made equal to that in the header tank tube at the beginning. The time taken for *L* to reach a maximum represents the response time for adjustment of the pitot manometer level by outflow through the small bore (0.6 mm diameter) of the pitot tube. The maximum loss with the fresher solution is greater than that with the older, but the aging process is evidently accelerated by the flow in the apparatus.

Fig. 1. Pitot tube apparatus.

Fig. 2. Pitot loss as a function of time.

Fig. 3. Pitot loss as a function of speed.

More dilute 'Polyox', of 20 p.p.m. concentration, shows only a very small pitot loss even when fresh, but at 50 p.p.m. concentration the loss is about half as great as at 70 p.p.m. Results for 'Separan' solutions of 100 and 130 p.p.m. concentration are similar to those for 'Polyox', except that the pitot loss does not diminish with aging to zero, but attains a final limiting value smaller than the maximum for fresh solution. Guar gum solution of 160 p.p.m. concentration shows no pitot loss at all.

For 70 p.p.m. 'Polyox' solution tested within 2 h of mixing the maximum pitot loss is shown as a function of pitot pressure  $P$ , or equivalently of jet speed  $V$ , in Fig. 3. At very low speeds there is no effect. Goren<sup>3</sup> suggests that at higher speeds than those of the present experiments the pitot loss may fall off, to diminish to zero at sufficiently high speeds. The reduction of pitot loss, however, with increasing speed which Goren<sup>3</sup> reported might be due to accelerated aging at the higher speeds in the turbulent flows of those experiments.

Turbulent drag reduction was measured in the rotating wheel rig we described elsewhere<sup>4</sup>. A flanged wheel rotates in a casing containing liquid, and the frictional torque exerted on the casing is measured and compared with the torque for the same speed of rotation when the liquid is replaced by the same amount of water. 'Polyox' solutions, aged in the pitot rig so as to show no remaining pitot loss, produced just as much drag reduction as freshly mixed solutions, with no greater tendency to degradation with time.

The viscosities of various solutions, some of which had been aged in the pitot rig of Fig. 1, and others of which had been degraded in the turbulent friction apparatus, were measured. A capillary instrument was used in which the wall shear rate was about 1,200 reciprocal seconds. Results are shown in Table 1. The measured viscosities can be compared with the value of 1.0038 centistokes

Table 1. VISCOSITIES OF VARIOUS SOLUTIONS

Case No.	Fluid	Kinematic viscosity (centistokes) at 20° C
1	130 p.p.m. 'Separan' aged in pitot rig	1.158
2	Same mixture not put into pitot rig	1.162
3	70 p.p.m. 'Polyox' aged in pitot rig	1.056
4	Same mixture not put into pitot rig	1.055
5	70 p.p.m. 'Polyox' degraded in turbulent flow rig	1.036
6	Same mixture not put into turbulent flow rig	1.056
7	70 p.p.m. 'Polyox' filtered 1 h after mixing, and viscosity of filtrate measured 5 h after mixing	1.081
8	Same fluid, 5 days later	1.064

for distilled water at 20° C. Concentrations quoted are only approximate.

In cases 1 to 6, the fluids were stored at rest for 5 or more days before the measurements were made. Evidently, aging in the pitot rig does not make the viscosity any different from that of liquid kept for several days at rest, but degradation in turbulent flow (so that the resulting fluid produces much less drag reduction than when fresh) reduces viscosity, probably as a result of molecular scission. Fresh solution has a higher viscosity than aged solution.

The apparent viscosity of both fresh and aged solutions in filtration is much greater than the figures given here. It was measured by the following procedure: 50 ml. of water was put into a funnel lined with wet fine grade filter paper, and the time for the first 30 ml. to pass through was found. When all the water had drained through, 50 ml. of the solution at the same temperature was put in and the time for the first 30 ml. to pass through again was found. The average value from several tests of the ratio of these times is the apparent viscosity ratio, because for a completely homogeneous fluid containing nothing to block the filter pores the time of filtration would be proportional to viscosity. For fresh 70 p.p.m. 'Polyox' solution, which had been previously filtered once to remove any undissolved impurities, the ratio was about 2.3, and for the same solution, aged either by leaving it to stand for five days or by circulating it in the pitot rig for three hours, it was about 1.4. After degradation in the turbulent flow rig, so that the drag-reducing effectiveness was only a quarter of its initial value, the ratio was about 1.1. The average filter pore size is of the order of  $3\mu$ , so at this scale the fluid evidently cannot be regarded as a continuum with the same rheological properties as for larger-scale flows. Presumably molecules or molecular aggregates of a size comparable with the pore diameter are present in the fluid.

The second normal-stress difference, between directions perpendicular to the streamlines, was investigated with the concentric-tube instrument we described elsewhere<sup>2</sup>. It had been found that 'Polyox' solutions, unlike solutions of guar gum or 'Separan', exhibited a significant second normal-stress difference. Further tests have now shown that this difference is less for solutions mixed 1-3 days previously than for freshly mixed solutions, while solutions aged in the pitot rig, so as to have zero pitot loss, also have zero normal-stress difference.

As described earlier<sup>4</sup>, a laminar jet of coloured 'Polyox' solution emerging from a capillary tube into uncoloured fluid and impinging obliquely on a flat surface may remain as a narrow jet over this surface, whereas a corresponding water jet spreads out into a wedge-shaped region. It now appears that narrow jets, probably attributable<sup>5</sup> to non-Newtonian tensile stresses along the streamlines, are characteristic only of fresh 'Polyox' solutions, for aged 70 p.p.m. solution has been found to behave like water. Thus here is another instance where non-Newtonian effects disappear with aging.

We have noted<sup>4</sup> that jets of coloured 'Polyox' solution squirted from a fine bore capillary into uncoloured 'Polyox' solution, so that the initially laminar jet became turbulent, in some cases showed a greatly modified turbulence structure. Other experiments on turbulent jets<sup>3,5,6</sup> at higher Reynolds numbers have suggested, however, that

the turbulence is unaffected by the additive. This discrepancy may be due to accelerated aging in these flows at higher Reynolds number which are initially turbulent rather than laminar, as it has now been found that even initially laminar jets of 'Polyox' solution, aged in the pitot rig, show much less drastically modified turbulence than jets of fresh solution.

Many of the anomalous non-Newtonian effects found for some dilute polymer solutions seem to diminish or disappear with aging, which may be accelerated by gentle mixing such as that which takes place in the pitot apparatus. This aging may simply represent a more complete dissolving of the additive, though Pruitt *et al.*<sup>7</sup> attributed it to polymer adsorption on the walls of the containing vessel, and Shin<sup>8</sup> to biological attack. Shin<sup>8</sup>, however, showed that while biological degradation could evidently be important over longer time periods, for periods of less than a week, over which large reductions of viscosity could occur, the turbulent drag reduction was little affected, which is in agreement with the present findings. The suggestion of polymer adsorption also seems hard to reconcile with undiminished turbulent drag reduction, which is more consistent with the suggestion, made to explain certain anomalous turbulence measurements by Fabula<sup>9</sup>, that molecular aggregates occur in freshly mixed solutions but tend to break up with aging. These molecular aggregates would appear to be the cause of some normal-stress difference effects in fresh solutions. 'Polyox' solution, which for the concentration range 50–100 p.p.m. shows marked non-Newtonian effects when fresh, is, when aged and thoroughly dissolved, not very different from water in all viscometric and rheogoniometric measurements so far tried, except those for which the flow passages are only a few microns wide. Thus it may well be impossible to find constitutive equations which are significantly non-Newtonian for such aged liquids. Because these liquids are still fully effective in producing turbulent drag reduction, it would seem to be difficult to explain that phenomenon in terms of non-Newtonian equations.

### Anomalies in Detonation Initiation of Liquid Explosives

ATTENTION has recently been directed to the study of low velocity detonations (LVD) (refs. 1 and 2), which propagate at velocities only slightly supersonic with respect to the unreacted liquid and may be very easily initiated in some liquids. It is the purpose of this communication to show that both the shape and material of the container and the presence of a witness plate affect LVD initiation. Theories proposed for LVD (refs. 1–3) require that the container sound speed be greater than that of the liquid explosive. We have tested this prediction by using lead tubes with 1,2-difluoroaminopropane, a liquid known to sustain normal and low velocity detonations<sup>4</sup>. Because of the low sound velocity, we expected that weak initiating shocks would not yield LVD in lead though identical shocks would in steel. Unexpectedly, there was definite

evidence of LVD propagation. The experiments were repeated and photographed with a high speed framing camera. The lead tubes used were 1.27 cm inner diameter  $\times$  0.635 cm wall  $\times$  10.4 cm long, and the shock source consisted of an exploding bridge-wire detonator, a small ( $\sim 1$  g) RDX pellet, two pressed tetryl pellets (each 3.87 cm diameter  $\times$  2.54 cm long; density  $\sim 1.51$  g/cc; weight  $\sim 90$  g), and a 'Plexiglas' attenuator (3.87 cm diameter  $\times$  30.5 cm long). The shock strength at the end of the attenuator was about 1 kbar compared with about 60 kbar required to initiate normal detonation.

Frames selected from the photographic record are shown in Fig. 1. The experiment was backlit with an electronic flashgun and the principal features appear as shadows. These include a transparent ruler and a notched strip to serve as fiducial markers, the lead tube (the large black rectangle in the upper half of each frame), and the 'Plexiglas'. Because of its shape the 'Plexiglas' transmitted a thin strip of light parallel to its axis. Irregularities at the 'Plexiglas'–lead interface arise from bits of cement used in assembling the shot. Numbers below each frame are the lapsed time from initiation of the detonator. Fig. 1(a) shows the still unshocked system. From independent measurements the time at which the shock reaches the 'Plexiglas'–lead interface is known. Then the lead expands and wrinkles (Fig. 1(b)). The air shock from the donor (marked by arrows) is apparent in the discontinuities across the ruler and the light strip along the 'Plexiglas' axis. (This situation may not be evident in the half-tone; a limited number of photographic prints are available from the author on request.) At 267  $\mu$ sec after initiation (Fig. 1(c)) the air shock has reached the lead which has now separated from the 'Plexiglas'. The

Fig. 1. Low velocity detonation in lead.

subsequent detonation is detectable in the very next frame but is more apparent at 292  $\mu$ sec (Fig. 1(d)).

These experiments show that a second mechanism may also produce LVD. In the low yield strength lead containers the imposed weak shock caused tube expansion and fragmentation of the liquid; the subsequent reaction is induced by the air shock. This sequence is similar to that proposed elsewhere<sup>2</sup> except that a high sound speed container is not required.

Experiments employing very weak shocks (too gentle to initiate either normal detonation or Mach zone LVD), steel tubes and thin steel witness plates were photographed in the same fashion. Still another mechanism of LVD initiation was discovered. It was calculated that the weak shock travelled barely supersonically along the container walls and was reflected by the terminal witness plate; on reaching the attenuator-liquid interface, LVD initiated and propagated in the direction of the original shock. LVD did not occur when the same tests were run without the witness plate.

In summary, LVD in high sound speed containers may arise from shock wave (Mach) interactions along the charge axis<sup>4</sup>, or reflexion of the shock wave from the witness plate. In low yield strength containers, LVD may be initiated subsequent to tube expansion, liquid fragmentation and air shock arrival.

Because of these many causes of detonation propagation, the results of routine detonability testing<sup>5</sup> are of limited value in establishing safe handling criteria.

### Theoretical Collision Efficiencies for Small Cloud Droplets in Stokes Flow

WHEN a cloud forms in the atmosphere, water vapour condenses on aerosol particles to form a relatively homogeneous distribution of small droplets, typically a few microns in radius. A principal problem in cloud physics is to understand the growth of droplets from this initial stage into drizzle drops with radii of several hundred microns. Under many conditions the most important growth process is that of collision and coalescence; in warm clouds all droplet growth subsequent to condensation proceeds in this way. It is therefore reasonable to emphasize the coalescence growth mechanism in numerical cloud models<sup>1-3</sup>.

The most widely accepted theory of small cloud droplet collisions under electrically neutral conditions is that of Hocking<sup>4</sup>, who treated interacting cloud droplets as spheres sedimenting in still air under conditions of stationary Stokes flow. One striking result of his analysis was the prediction that no collisions between cloud droplets can occur if both radii are less than 19 $\mu$ . But because the droplet population after initial condensation very often fails to contain a significant number of droplets with radii larger than this cut-off, it is difficult to understand how the droplet growth process gets started<sup>5</sup>. In order to

grow large drops in numerical cloud models it has been necessary to postulate an initial distribution containing droplets with radii larger than 19 $\mu$  or to provide some *ad hoc* mechanism to initiate the coalescence process.

We have re-examined the theory of the collisions of small cloud droplets, assuming, with Hocking<sup>4</sup>, that steady Stokes flow conditions apply. In contrast with Hocking's results, we do not find any cut-off in droplet collisions, even for droplets with radii as small as 5 $\mu$ .

We treated the problem of small droplet collisions by assuming that for droplets with radii smaller than 30 $\mu$  the steady-state Stokes hydrodynamic theory would be adequate to determine drag forces. The droplets were assumed to be rigid spheres, which should be valid for the very small droplets of interest, because of their high internal fluid pressure. Electrical effects were omitted. Collision efficiencies were computed by integrating the equations of motion of pairs of droplets sedimenting in still air;  $y_c$ , the initial horizontal off-set resulting in a grazing trajectory, was found by a successive approximation process, as in Hocking<sup>4</sup>. A "collision" was taken, by convention, to be any approach to within 0.001 times the radius, or less, of the larger droplet. This procedure took account approximately of short-range forces at small separations of the droplet surfaces; it was found that the results were relatively insensitive to the exact cut-off distance used.

We have developed independently the drag forces on the two spheres. One approach (RAND) was to use the Stimson and Jeffery<sup>6</sup> and Maude<sup>7</sup> solution for the component of motion along the line of centres, together with Hocking's expressions, corrected for the effect of rotation, for motion perpendicular to the lines of centres. A preliminary report<sup>8</sup> on this approach has pointed out that several of Hocking's drag expressions are in error when the spheres are close together. The other method (NCAR) was to extend Hocking's expressions by including many more terms, giving particular care to considerations of numerical stability. We used these forces in separate integration routines to derive collision efficiencies<sup>\*</sup>. Our separate calculations predict collision efficiencies that differ from each other by no more than a few per cent.

Our results (from the RAND calculations) appear in Fig. 1, which also shows Hocking's results for 30 $\mu$  and 20 $\mu$  drops for comparison (he predicted no collisions for 10 $\mu$  drops). Differences include the disappearance in our results of the 19 $\mu$  cut-off, as well as the prediction of finite collision efficiencies both for droplets that differ considerably in size and for those which are nearly the same size; in fact our calculations showed finite collision efficiencies for all values of  $(b/a) > 0$ . Another difference evident in Fig. 1 is that the maxima of our collision efficiency curves are systematically somewhat smaller than Hocking's for  $a \geq 20\mu$ . We do not have a qualitative explanation for the confluence of our curves to a finite value for  $b/a \rightarrow 1.0$ .

Numerical studies suggest that Hocking would not have found a 19 $\mu$  cut-off in collision efficiencies had he used the Stimson-Jeffery<sup>6</sup> solution for that part of the problem which they treated, rather than his own solution (or if he had extended his expressions to a higher order). We are confident that the Stokes hydrodynamic theory does not predict such a cut-off for the Stimson-Jeffery theory is well substantiated both theoretically and experimentally<sup>9</sup>. Sensitivity studies indicate that varying such parameters as the cut-off distance used as a collision criterion can lead to differences in computed collision efficiencies of up to 20 per cent of the reported value. Although we believe that our values plotted in Fig. 1 are more reliable than this, it is possible that further studies may show discrepancies of this magnitude. Application of these results to studies of droplet growth requires knowledge of the

\* The definition of collision efficiency used here is that used by Hocking:  $(y_c/a)^2$ , the square of the ratio of the initial horizontal off-set for a grazing trajectory to the radius of the larger drop.

## CHEMISTRY

## Gas-Solid Chromatography on Organic Crystals

THE full potential of gas-solid chromatography has not yet been revealed. Theoretically it could be used to obtain much greater selectivity and higher efficiency than gas-liquid chromatography<sup>1-4</sup>. So far the characteristics required of an adsorbent have limited the use of gas-solid chromatography.

For successful analyses an adsorbent should have a homogeneous surface, a relatively small adsorption enthalpy, a convenient surface area and should be easily prepared. A heterogeneous surface will give rise to tailing peaks. A large adsorption enthalpy requires that separation be performed at a high temperature, when the thermal stability of the compounds may be poor. If the surface area is too large the result is the same and if it is too small, efficiency is poor. Usually a specific surface area of 4 to 10 m<sup>2</sup>/g is satisfactory.

Until recently only graphitized carbon black, which has a high specificity in various separations, met these requirements<sup>2,3,5</sup>. This contrasts with the versatility of gas-liquid chromatography using several hundred stationary phases. If gas-solid chromatography is to develop further a method for preparing large numbers of adsorbents which fulfil the requirements for high efficiency must be found. We propose that crystallized organic compounds coated on graphitized carbon black be used for preparing suitable adsorbents of various selectivities for gas-solid chromatography.

Many organic compounds have a high melting point, a small vapour pressure and show good thermal stability. Phthalocyanines, quinaeridones and other types of dyes—polynuclear hydrocarbons—can withstand temperatures greater than 300° C, and only sublime slowly. If lower temperatures only are required there are hundreds of possible compounds.

It is impossible, however, to use columns packed with pure organic crystals: crystals of most compounds have

Fig. 1. Collision efficiency,  $(y/a)^2$ , versus the droplet radius ratio,  $(b/a)$ , for several values of the larger radius,  $a$ . —, Present results; ---, Hocking (ref. 4). The arrowheads at the points where Hocking's curves touch the bottom of the figure indicate that his curves go to zero at these points.

probability that two colliding droplets will coalesce. The available evidence suggests that coalescence probability is near unity for small cloud droplets<sup>10</sup>, but the question merits further investigation. Probably the most important reservation about our results comes from our use of time-independent Stokes hydrodynamics. Further improvement awaits a more general solution for fluid flow around two spheres.

Recent experimental studies of small droplet collection efficiencies (collision followed by coalescence) are summarized in the paper of Woods and Mason<sup>10</sup>. They were able to set an approximate upper limit experimentally on collection efficiencies for droplets with radii 17–19  $\mu$  interacting with droplets of radii 10–14  $\mu$ . Their limit of 0.1 (expressed according to our definition of a "collision efficiency") does not disagree with our findings, for we predict a finite collision efficiency of about 0.1 for this case. Our findings are also in qualitative agreement with their observation of finite collection efficiencies for  $(b/a) \leq 0.1$ .

Fig. 1. Analysis of a mixture of polynuclear aromatic hydrocarbons. The column was 1 m long with an internal diameter of 2 mm, and was packed with 1 per cent copper phthalocyanine on graphitized carbon black Sterling M T (Cabot). Temperature 265° C. Carrier gas was hydrogen, with an outlet velocity of 25 cm/sec. (1) Naphthalene; (2) diphenyl; (3) 1-methylnaphthalene; (4) 2-methylnaphthalene; (5) acenaphthene; (6) fluorene; (7) phenanthrene; (8) anthracene.

no mechanical stability; their surface area is very small, which gives very small column efficiency and loadability, as shown by the previous results with crystallized copper amine complexes and several pure phthalic derivatives used as column packing<sup>6-9</sup>.

A solid support with a function similar to that of a catalyst is needed. In gas-solid chromatography, however, it is impossible for the solid support to be completely inert, and we can only try to minimize its influence. Because surface homogeneity is essential graphitized thermal carbon black is much better than 'Chromosorb' for the analysis of polar compounds, as shown by the results obtained with 'Chromosorb' coated with benzophenone<sup>10,11</sup> and copper amine complexes<sup>12</sup>.

Excellent chromatographic results, however, can be obtained with anthraquinone<sup>13</sup> or copper phthalocyanine (Fig. 1) coated on graphitized carbon black. With the latter compound high efficiency has been obtained for various phenols<sup>14</sup>, aniline and nitrobenzene.

The high retention of anthracene relative to phenanthrene (1-16 at 265° C) is also unusual as is the high specificity to xylene isomers, which is much larger than the specificity of uncoated carbon black. The column is stable at 300° C for several weeks at least.

Results obtained with columns of other metal phthalocyanines are similar to previous ones<sup>15</sup>, but with a higher specificity, better thermal stability and more efficiency.

### Rate of H-abstraction by OH from Hydrocarbons

FLASH photolysis of mixtures of water and argon can produce hydroxyl radicals with a spectroscopically detectable lifetime sufficient to allow kinetic investigations to be carried out. This was achieved by Black and Porter<sup>1</sup> and Greiner<sup>2,3</sup> with a vacuum ultra-violet flash photolysis apparatus; in our case a standard apparatus was modified by using a flash lamp and a reaction vessel made of Spectrosil quartz (which transmits ultra-violet radiation down to 1620 Å (ref. 4)) and by flowing dried nitrogen through the reflector for about 1 h before and during each experiment to displace atmospheric oxygen and water vapour. Water was used as the precursor of hydroxyl radicals because H-abstraction by OH cannot affect the OH concentration, whereas H-abstraction from any other substrate results in rapid OH-decay. Furthermore, the system is simple, because radiation absorbed by the first absorption region of water vapour (1400-1850 Å) causes only one photochemical reaction<sup>1,5,6</sup>.

The following reactions of OH can then occur

Black and Porter<sup>1</sup> determined third order rate constants in various gases for reactions (1) and (2) at room temperature. The relative values for these rate constants are valid, but the absolute values are low because they were based on  $k_1 + 2k_2 = 1,400 \text{ mm}^{-2} \text{ sec}^{-1}$ , obtained by Oldenberg and Rieke<sup>7</sup>, who used an electrical discharge through water as the source of hydroxyl radicals in a flow system. Kaufman and Del Greco<sup>8</sup> have shown that such a discharge is a poor source of OH, as the observed OH was produced not only in the discharge, but throughout the length of the flow system, probably by the reactions  $\text{H} + \text{O}_2 + \text{M} \rightarrow \text{HO}_2 + \text{M}$  and  $\text{H} + \text{HO}_2 \rightarrow 2\text{OH}$ . Absolute rate constants for reactions (1) and (2) have recently been obtained by Caldwell and Back<sup>9</sup> by comparing the rates of these reactions with the rate of reaction (3), as determined by Del Greco and Kaufman<sup>10</sup>. Bearing in mind that the correction factor derived by Caldwell and Back<sup>9</sup> is too high by a factor of 2, because the rate constant  $k_3$  was defined differently by Black and Porter<sup>1</sup> and Del Greco and Kaufman<sup>10</sup>, it is possible to calculate the overall rate constant for the decay of OH by reactions (1)-(3) after flash photolysis of mixtures of water and argon at room temperature.

We have found that flash photolysis of 8 mm H<sub>2</sub>O/300 mm Ar mixtures produced OH which underwent second order decay with a detectable lifetime of greater than 2 msec (see Fig. 1). The relative concentrations of OH were determined from OH spectral intensities, using a calibration curve prepared by the conventional two path length method<sup>11</sup>. From the gradient of a second order plot and the calculated total rate constant at 25° C

$$\{k_1(\text{Ar}) + 2k_2(\text{Ar})\} [\text{Ar}] + \{k_1(\text{H}_2\text{O}) + 2k_2(\text{H}_2\text{O})\} [\text{H}_2\text{O}] + 2k_3 = 2.2 \times 10^{10} \text{ l. mole}^{-1} \text{ sec}^{-1} \quad (i)$$

the OH concentration at 100 μsec was determined as  $5.5 \times 10^{-7} \text{ mole l.}^{-1}$ . The decay of hydroxyl radicals was studied as a function of temperature in the range 25°-150° C

Fig. 1. Decay of OH after flash photolysis of H<sub>2</sub>O (8 mm) and Ar (300 mm) at 23° C.

and the resultant Arrhenius plot of the overall rate constant was found to be curved. The "activation energy" was approximately  $-2$  kcal/mole at  $25^\circ\text{C}$  and between  $-1$  and  $0$  kcal/mole at  $150^\circ\text{C}$ . The curvature of this plot arises because of the opposition of reactions (1) and (2), which have negative activation energies, and reaction (3), which has a positive activation energy,  $E_3 = 1.0 \pm 0.5$  kcal/mole<sup>12</sup>. The relative magnitudes of the various terms in equation (i) show that the contribution from the third order reactions (1) and (2) to the overall decay rate at  $25^\circ\text{C}$  is 93 per cent, whereas at  $150^\circ\text{C}$  reactions (1) and (2) are relatively less important, though still predominant as shown by the negative temperature coefficient.

These results characterize the water/argon system, and so it is now possible to investigate the reaction of hydroxyl radicals with certain hydrocarbons by photolysing  $\text{RH}/\text{H}_2\text{O}/\text{Ar}$  mixtures. We wish to report here an estimate of the rate constant for the reaction

The addition of less than 1 mm  $\text{C}_2\text{H}_6$  to 8 mm  $\text{H}_2\text{O}/300$  mm Ar mixtures at room temperature resulted in a greatly increased rate of OH decay which was close to first order. Reactions of radicals derived from ethane are excluded because ethane does not absorb light above  $1620 \text{ \AA}$  (ref. 13), the limit of Spectrosil transmission<sup>4</sup>.

The decay of OH is therefore adequately described by the kinetic equation

$$-\frac{d[\text{OH}]}{dt} = k_1[\text{OH}][\text{C}_2\text{H}_6] + \left\{ k_1(\text{Ar}) + 2k_2(\text{Ar}) \right\} [\text{Ar}] + \left\{ k_1(\text{H}_2\text{O}) + 2k_2(\text{H}_2\text{O}) \right\} [\text{H}_2\text{O}] + 2k_3 [\text{OH}]^2$$

The results were plotted in the form  $-d \ln[\text{OH}]/dt$  v.  $[\text{OH}]$ . Fig. 2 shows such a plot for the decay of OH at  $25^\circ\text{C}$ . Because the rate constant for the decay of OH by reactions (1)–(3) at  $25^\circ\text{C}$  had already been calculated as  $2.2 \times 10^{10} \text{ l. mole}^{-1} \text{ sec}^{-1}$ , see equation (i), insertion of this value for the gradient in Fig. 2 reduced the error in determining the intercept. Similar plots were constructed for the decay of OH in  $\text{C}_2\text{H}_6/\text{H}_2\text{O}/\text{Ar}$  mixtures in the temperature range  $25^\circ\text{--}150^\circ\text{C}$ . At each temperature, the previously determined rate constant for the decay of OH by reactions (1)–(3) was inserted as the gradient. The values of  $k_4$ , obtained from the intercepts of these plots, gave a linear Arrhenius plot and  $k_4$  was determined as

$$\log_{10} k_4 = (11.1 \pm 0.7) - (3,600 \pm 600)/2.303 \text{ RT l. mole}^{-1} \text{ sec}^{-1}$$

Similar but less numerous experiments on the methane/water/argon system led to an approximate estimate of the rate constant for the corresponding reaction

These values for  $k_4$  and  $k_5$  are significantly different from those reported by Avramenko and Kolesnikova<sup>14</sup>,

Fig. 2.  $-\frac{d \ln [\text{OH}]}{dt}$  plotted against  $[\text{OH}]$  for a mixture of 0.4 mm  $\text{C}_2\text{H}_6$ , 8 mm  $\text{H}_2\text{O}$  and 300 mm Ar at  $25^\circ\text{C}$ .

$\log_{10} k_4 = 11.1 - 5,500/2.303 \text{ RT l. mole}^{-1} \text{ sec}^{-1}$  and  $\log_{10} k_5 = 11.4 - 8,300/2.303 \text{ RT l. mole}^{-1} \text{ sec}^{-1}$ . They used, however, an electrical discharge through water as the source of OH radicals, a system which has been criticized by Kaufman and Del Greco<sup>8</sup>. On the other hand, the values at room temperature obtained by Greiner<sup>2,3</sup>,  $k_4 = 1.76 \times 10^{11} \text{ l. mole}^{-1} \text{ sec}^{-1}$  and  $k_5 = 5.3 \times 10^9 \text{ l. mole}^{-1} \text{ sec}^{-1}$ , are 40 per cent and 55 per cent lower than the results presented here.

## BIOCHEMISTRY

### Counter-current Distribution of Rapidly Labelled RNA from Rats treated with Hormones

WE have failed to confirm the report<sup>1</sup> that the injection of several hormones into rats is followed by rapid and specific alterations in the profile obtained by counter-current fractionation of "rapidly labelled RNA" from the liver. We consider that the alterations of profile described could have resulted from slight differences in the procedures for isolating RNA from experimental and control rats. In our work, we have used double labelling to eliminate the possibility of such differences: animals treated with hormones received a tritium precursor while control animals received a carbon-14 precursor and the livers were combined before isolation and fractionation of RNA.

Counter-current distribution was performed over fifty or eighty exchanges in a hand operated machine containing 1.5 ml. of each phase of solvent system 150/12.5, essentially as described by Kidson and Kirby<sup>1</sup>.  $^{14}\text{C}$  and  $^3\text{H}$  in the fractions were counted simultaneously in a Beckman liquid scintillation spectrometer.

Fig. 1 shows the radioactivity profiles of the labelled RNA isolated by the method of Kidson, Kirby and Ralph<sup>2</sup> from the livers of two rats, one of which had been given insulin and  $^3\text{H}$ -orotic acid and the other  $^{14}\text{C}$ -orotic acid without insulin. The tritium and carbon-14 counts have been plotted on scales that give the same area under each profile. There are no essential differences between the two profiles, and there was none in another similar experiment, or in experiments in which hydrocortisone (5 mg) or thyroxine (30  $\mu\text{g}$ ) were injected 50 or 35 min respectively before death and in which labelled orotic acid was injected 20 min before death.

In further experiments, liver slices were incubated in Ringer-bicarbonate buffer<sup>3</sup> with a hormone and  $^3\text{H}$ -adenine, while control slices were incubated with  $^{14}\text{C}$ -adenine without hormone, and the labelled RNA isolated by Method II of Kirby<sup>4</sup>. Fig. 2 shows a typical

experiment in which there are again no differences between the two profiles, although the labelled RNA has not travelled so far along the apparatus as that in Fig. 1. Similar profiles were obtained in six similar experiments in which corticosterone (500  $\mu$ g), oestradiol (50  $\mu$ g), or 3,3',5-triiodothyronine (50  $\mu$ g) was added for 30 min.

The movement of the rapidly labelled RNA can be expressed on a linear scale between 0 and 1 by the following "index of travel". The tube is found where one-half of the radioactivity in the apparatus is in tubes later than itself. The number of this tube is divided by the total number of exchanges. In eight experiments in which the RNA was isolated as in Fig. 1 (ref. 2), the mean index of travel was  $0.36 \pm 0.020$  (S.E.M.). In six experiments in which the RNA was isolated as in Fig. 2 (ref. 4), the mean was  $0.22 \pm 0.008$ . Thus it is clear that large changes in profile can result from a slightly altered method of preparation. Hence, smaller changes could well result from smaller and unavoidable differences in preparation between experimental and control rats.

The labelled RNA in Fig. 1 probably moves more rapidly than that in Fig. 2 because it is degraded more by an intrinsic ribonuclease. Thus when material prepared as in Fig. 2 was stored at 2°C for some weeks its index of travel increased from 0.19 to 0.33. Also, predigestion with pancreatic ribonuclease (10  $\mu$ g for 60 min at 37°C) increased the index for both materials to about 0.52. The material of Fig. 1 contains DNA but little ribosomal RNA while that of Fig. 2 contains ribosomal

RNA but little DNA. Association of the rapidly labelled RNA with DNA or ribosomal RNA, however, does not seem to account for the different rates of movement. Thus the rates were unaltered by adding calf thymus DNA to the material of Fig. 2 or by adding ribosomal RNA to that of Fig. 1 or predigesting it with deoxyribonuclease (ribonuclease-free).

### Insulin in the Cerebrospinal Fluid

STUDIES involving injection of labelled insulin have been interpreted as evidence that insulin does not pass into brain<sup>1,2</sup> or cerebrospinal fluid (CSF)<sup>3</sup>. Neither was any significant amount of insulin detected in human CSF using the rat adipose tissue bioassay technique<sup>3,4</sup>. We have reinvestigated the question of whether insulin passes the blood-CSF barrier using the more sensitive and specific radioimmunoassay technique.

Experiments were carried out on male and female dogs (10–15 kg) which had been fasted for 18–20 h and anaesthetized with sodium pentobarbital (30 mg/kg, intravenously). Samples of cerebrospinal fluid (1.5 ml.) were taken from the cisterna magna through a No. 22 spinal needle, which was left in place when the concentrations of insulin in the CSF were followed over a period of time. Blood samples were taken from the jugular vein through a polyethylene catheter. Crystalline beef insulin and glucose were infused into the saphenous vein. Concentrations of insulin in the plasma and CSF were determined by an adaptation of the radioimmunoassay of Yalow and Berson<sup>5</sup> to the double-antibody immunoassay method of Morgan and Lazarow<sup>6</sup>. Because we anticipated that the concentration of insulin in the CSF in the basal state would be very low, larger samples were taken of CSF (0.4 ml.) than of plasma (0.05 ml.) for the assay. In this way, the absolute amount of insulin in each assay tube was usually greater for CSF than for plasma.

Insulin was infused at 0.2 or 1.0  $\mu$ /kg/h. Glucose was also infused, at rates which either just prevented hypoglycaemia (about 750 mg/kg/h for 0.2  $\mu$ /kg/h of insulin) or produced hyperglycaemia (0.9–1.5 g/kg/h for both the high and low insulin dosage). All dogs had a normal basal concentration of plasma glucose ( $109 \pm 13$  mg per cent).

Insulin was found in the cerebrospinal fluid of all twenty-two normal dogs examined after treatment (Table 1). The average concentration of insulin in the CSF was 3  $\mu$ /ml., or 27 per cent of the average concentration of plasma insulin (11  $\mu$ /ml.) observed in these animals. When concentrations of plasma insulin were increased by intravenous infusion of insulin, the CSF insulin values rose between two- and seventy-fold. Although the greatest increases in CSF insulin were obtained when

Fig. 1. Counter-current distribution profile of rapidly labelled RNA from livers of control rats and rats treated with insulin. One rat received insulin (1 mg in 0.5 ml. of 0.003 normal HCl) intraperitoneally 35 min before death followed by <sup>3</sup>H-uric acid (200  $\mu$ c.; 0.22  $\mu$ mole in 0.45 ml. of 0.15 molar NaCl) 15 min later; the other control rat received HCl alone 35 min before death, followed by <sup>14</sup>C-uric acid (10  $\mu$ c.; 0.22  $\mu$ mole) 15 min later. Livers of the two rats were combined before RNA isolation<sup>2</sup>. ○ — ○, Carbon-14 counts (control); ● — ●, tritium counts (insulin treated).

Fig. 2. Profiles of rapidly labelled RNA from control slices of rat liver and slices incubated with insulin. One sample of slices (1 g) was incubated at 37°C for 1 h under oxygen (95 per cent) and carbon dioxide (5 per cent) in Ringer-bicarbonate buffer (10 ml.) containing glucose (30 mg) and insulin (50  $\mu$ g); <sup>3</sup>H-adenine (200  $\mu$ c., 0.35  $\mu$ mole) was added for the last 30 min. The control slices were treated identically except that no hormone was added and <sup>14</sup>C-adenine (10  $\mu$ c., 0.35  $\mu$ mole) replaced <sup>3</sup>H-adenine. The slices were combined before RNA isolation<sup>4</sup>. ○ — ○, Carbon-14 counts (control); ● — ●, tritium counts (with insulin).

Table 1. CONCENTRATION OF INSULIN IN PLASMA AND CEREBROSPINAL FLUID OF DOGS

	Insulin concentration (mean $\pm$ S.E.M.)	
	Plasma	CSF
	$11 \pm 1.2$ $\mu$ /ml.	$3 \pm 0.3$ $\mu$ /ml.
	(N = 22)	

plasma insulin values were raised to 1,000–2,000  $\mu\text{U}/\text{ml.}$ , even in the presence of plasma insulin concentrations in the more physiological range of 150–300  $\mu\text{U}/\text{ml.}$ , the CSF insulin concentration increased up to ten-fold (Fig. 1).

The concentration of plasma glucose did not appear to affect the passage of insulin from plasma to CSF, and although very high concentrations of plasma insulin were maintained for several hours, the CSF concentration of insulin did not increase proportionally (Fig. 2). This suggests that insulin passes into the CSF by way of a saturable transport system rather than by passive diffusion.

The reports that insulin penetrates only slightly, if at all, into the brain and CSF, have been based either on the detection of radioactivity after injection of labelled insulin or on the measurement of "insulin like activity" using the adipose tissue bioassay technique. Both these approaches have limitations. In one study<sup>2</sup> the concentration of radioactivity in brain 15 min after intravenous injection of insulin labelled with iodine-131 was lowest of any tissue examined with the exception of erythrocytes. Skeletal muscle and adipose tissue, however, both of which are sensitive to insulin, had only slightly greater amounts of radioactivity. Insignificant amounts of radioactivity were found in lumbar CSF up to 90 min after intravenous injection of labelled insulin<sup>3</sup>. These studies are difficult to interpret as evidence either for or against the passage of insulin across the blood-brain barrier. Considering the rapid metabolism of insulin<sup>5</sup> and its slow passage across the blood-CSF barrier as shown here, measurable amounts of labelled insulin are not likely to be found in the brain or CSF after a single injection.

In studies on CSF, Mahon *et al.*<sup>3</sup> used the rat adipose tissue bioassay technique to determine "insulin like activity" (ILA). They reported an average serum ILA of 371  $\mu\text{U}/\text{ml.}$  in five subjects, with less than 31  $\mu\text{U}/\text{ml.}$  in the CSF. This concentration was the lowest point on their standard curve. Schrader and Weinges<sup>4</sup> found serum concentrations of ILA averaging 320  $\mu\text{U}/\text{ml.}$  and

Fig. 1. Effect of infusion of intravenous insulin on insulin concentration in plasma (—) and CSF (---).  $\circ$ , Values obtained during infusion of 0.2  $\text{U}/\text{kg}/\text{h}$ ;  $\blacktriangle$ , values obtained during infusion of 1  $\text{U}/\text{kg}/\text{h}$ . Insulin concentration is plotted on a logarithmic scale.

Fig. 2. Relationship between plasma (white columns) and CSF (hatched columns) insulin concentrations at three concentrations of plasma insulin. A represents the basal state, B and C the situation 4 h after insulin infusions of 0.2 and 1  $\text{U}/\text{kg}/\text{h}$ , respectively.

less than 10  $\mu\text{U}/\text{ml.}$  of ILA in the CSF in ten metabolically normal subjects. Although the adipose tissue bioassay may be useful in studies of metabolism, it lacks the specificity and sensitivity of the radioimmunoassay. The ILA in the cerebrospinal fluid in the studies referred to represents less than 3 per cent<sup>4</sup> and 8 per cent<sup>3</sup> of the serum ILA. Our value of 3  $\mu\text{U}/\text{ml.}$  for the average CSF insulin concentration, although small in absolute terms, nevertheless represents a substantial fraction (27 per cent) of the true plasma insulin concentration.

This work also reveals that concentrations of CSF insulin increase after an increase in plasma insulin. The entry of insulin would appear to be quite slow, however, judging from the 3–4 h required for insulin levels to stabilize in the CSF during continuous intravenous infusion of insulin (Fig. 1). Although these experiments indicate that insulin is able to cross the blood-CSF barrier (and presumably also the blood-brain barrier), the physiological significance of this remains to be elucidated.

### Distribution of Acid Glycosaminoglycans in Human Articular Cartilage

THERE is evidence<sup>1,2</sup> that the distributions of chondroitin sulphate and keratansulphate in both articular and costal cartilage are different and change with age. The concentration of keratansulphate has been shown to increase with distance from the periphery of the cartilage using 'Alcian Blue' (8GX, I.C.I. Ltd.) in graded concen-

trations of magnesium chloride, according to the "critical electrolyte concentration" technique<sup>3</sup>, with or without hyaluronidase digestion. In mature human articular cartilage, chondroitin sulphate is predominantly territorial while keratansulphate is characteristically interterritorial, except in the deepest zones (adjacent to the calcified layer) of older tissue, where keratansulphate is localized close to the chondrocyte.

It is necessary to compare these histochemical findings with biochemical measurements of the relevant materials. The superficial, middle and deep zones of articular cartilage are easily separable by sectioning tangential to the articular surface, and because, histochemically, the concentrations of chondroitin sulphate and keratansulphate vary considerably between these layers, it seemed worthwhile to analyse them by micro-biochemical methods. Macroscopically normal articular cartilage from human post-mortem femoral condyles was cut tangentially into sections about 0.2 mm thick, each section being about 15 mg wet weight. The tissue was digested at 65°C with papain<sup>4</sup> and polyanions were precipitated with 1 per cent cetyl pyridinium chloride (CPC) at 0.35 molar sodium chloride. The CPC complex was dissociated with either 2 molar sodium chloride or 4 normal hydrochloric acid, and CPC was removed by chloroform extraction<sup>5</sup>. Uronic acid was determined by the borate modification of the Dische carbazole method<sup>6</sup>, and hexose by the method of Dische<sup>7</sup>, on samples of the polysaccharide solution. Ratios of glucosamine to galactosamine were determined on 4 normal hydrochloric acid hydrolysates (100°C for 8 h) of the polysaccharide, by the method of Scott<sup>8</sup>, using naphthyl isothiocyanate. Sections 10 µm thick of tissue adjacent to that used for quantitative analysis were stained in 0.1 per cent w/v 'Alcian Blue' in 0.4 molar and 0.9 molar magnesium chloride<sup>1</sup>.

Table 1. HUMAN POST-MORTEM ARTICULAR CARTILAGE

Depth from surface (ratio to total depth)	Uronic acid as glucuronic lactone (% dry wt.)	Hexose as galactose (% dry wt.)	Molar ratio: hexose/hexose + uronic acid	Molar ratio: glucosamine/glucosamine + galactosamine
0.1	0.41	0.20	0.32	0.32
0.3	1.51	0.77	0.32	0.18
0.4	1.91	0.87	0.29	0.24
0.6	2.07	1.13	0.33	0.33
0.7	2.07	1.34	0.38	—
0.8	1.80	1.43	0.42	0.32
0.9	1.76	2.30	0.53	0.34
0.95	1.28	2.08	0.59	0.41

Medial femoral condyle. Male aged 31 yr. Analytical values for successive tangential sections.

Table 2. HUMAN POST-MORTEM ARTICULAR CARTILAGE

Region in cartilage	Uronic acid as glucuronic lactone (% dry wt.)	Hexose as galactose (% dry wt.)	Molar ratio: hexose/hexose + uronic acid
Superficial zone (SZ) (<0.25 mm from articular surface)	0.77 ± 0.30	0.45 ± 0.20	0.34 ± 0.064
Middle zone (MZ)	2.13 ± 0.60	1.46 ± 0.54	0.39 ± 0.042
	Difference from SZ: $t = 5.0, P < 0.001$	Difference from SZ: $F = 18.0, P < 0.01$	
Deep zone (DZ) (<0.20 mm from calcified layer)	1.25 ± 0.61	1.72 ± 0.60	0.56 ± 0.070
	Difference from MZ: $t = 2.53, P < 0.05$	Difference from MZ: $t = 5.3, P < 0.001$	

Mean values ± 1 standard deviation.

Medial femoral condyle. Mean values for superficial, middle and deep zones in six adult cases aged 31–78 yr.

The results of a representative case are shown in Table 1, and mean values for six adult specimens are shown in Table 2. The histochemical findings (see Fig. 1A and B) are supported by the present biochemical investigations. (1) Uronic acid (representative of chondroitin sulphate) is maximal in the middle zone, while hexose (representative of keratansulphate) increases with distance from the articular surface. (2) The ratios hexose: hexose + uronic acid and glucosamine: glucosamine + galactosamine both rise sharply in the deep zone.

Glucosamine and hexose are less reliable indicators of keratansulphate than are galactosamine and uronic acid of chondroitin sulphate. Thus galactose and xylose are present in the linkage region of chondroitin sulphate to protein<sup>9</sup> while the exact composition of keratansulphate is uncertain<sup>10</sup>. Precipitation of the CPC complexes at 0.35 molar sodium chloride probably eliminates severe contamination by non-sulphated polyanions while minimizing losses of low molecular weight acid glycosaminoglycan.

Fig. 1. A, Human articular cartilage. Medial femoral condyle. Aged 31 yr. 0.1 per cent 'Alcian Blue' at 0.4 molar magnesium chloride, pH 5.7. Staining attributed to chondroitin sulphate and keratansulphate. ( $\times 50$ .) B, as A but stained at 0.9 molar magnesium chloride. Staining attributed to high molecular weight keratansulphate; note increase with depth from articular surface. ( $\times 50$ .)

Szirmai *et al.*<sup>11</sup> found a similar pattern of distribution in horse nasal cartilage, apparently with much less keratansulphate. The various types of hyaline cartilage appear to differ in the proportion of keratansulphate in the total glycosaminoglycan content. Thus human costal cartilage has a higher proportion of keratansulphate<sup>12,13</sup> than either horse nasal<sup>11</sup> or human articular cartilage. It is possible that the differences in the composition of these skeletal elements may be associated with differences in their physical properties—for example, permeability.

In adult articular cartilage, the variation of keratansulphate distribution with depth from the joint surface is similar in form to that in costal and horse nasal cartilage with respect to distance from the perichondrium. There is evidence that the synovial fluid is the principal source of nutrition of adult articular cartilage<sup>14</sup>. If this is so, the distribution of keratansulphate in this tissue is in agreement with the speculation made by Stockwell<sup>1</sup> that an increase in the distance from a source of oxygen supply is a principal determining factor for an increase in the ratio of keratansulphate to total acid glycosaminoglycan.

This appears to be the first time that a relatively specific histochemical staining technique for acid glycosaminoglycans has been correlated with the results of microchemical analysis. The two sets of data are compatible

and therefore substantiate the claims made for the histochemical method.

## Changes in Nucleic Acid Metabolism of Tumour Cells under High Pressure Oxygen

THE radiosensitizing effect of oxygen<sup>1-6</sup> has been extensively studied not only in radiobiology but also in clinical radiotherapy, but knowledge of the biological action of high pressure oxygen *per se* is rather scanty. We have examined the effects of high pressure oxygen on the nucleic acid metabolism of Yoshida ascites hepatoma cells *in vitro* and Ehrlich ascites tumour cells *in vivo*.

Yoshida ascites hepatoma cells (AH 130) were inoculated into the peritoneal cavity of male rats of the Donryu strain weighing 200 g. On the seventh day after inoculation, ascites tumour cells were collected, washed in phosphate buffered saline and suspended in 10 volumes of a tissue culture medium consisting of lactalbumin hydrolysate, yeast extract and 10 per cent calf serum. Cell suspensions were pressurized in a small oxygen chamber and irradiated with a deep therapy machine, 300 kV, General Electric 'Maxitron', operated at 20 m.amp, filtered through 2.0 mm copper, which resulted in a half value layer of 1.77 mm copper and a dose rate of 240 r./min at a distance of 35 cm. After irradiation, tritiated thymidine (thymidine-methyl-T, 5 c./mmole) or <sup>14</sup>C-thymidine (thymidine-2-<sup>14</sup>C, 35 mc./mmole) plus tritiated uridine (uridine-5-T, 3c./mmole) were added, high pressure oxygen or nitrogen was again introduced and the cells were incubated for 30 min at 37° C with constant shaking. After incubation 1/10 volumes of cold 50 per cent trichloroacetic acid were added and nucleic acid fractions were separated according to the method of Schmidt and Thannhauser<sup>7</sup>. The radioactivity of the nucleic acid fractions was determined by a liquid scintillation spectrometer using a dioxane-toluene phosphor<sup>8</sup>. DNA was measured according to the method of Burton<sup>9</sup> and RNA according to Dische<sup>10</sup>.

Table 1 shows the effects of pressurization on the *in vitro* incorporation of tritiated thymidine into DNA of the ascites hepatoma, and Table 2 shows the effects of irradiation under high pressure oxygen on the *in vitro* incorporation of <sup>14</sup>C-thymidine and tritiated uridine into DNA and RNA of the ascites hepatoma cells. The effects of irradiation under high pressure oxygen were slightly greater than those of irradiation in air when the enhancement of incorporation by high pressure oxygen *per se* was taken into account.

Similar experiments have also been carried out *in vivo*. Because of the limited size of the oxygen chamber, we

used mice as the experimental animals. Ehrlich ascites tumour cells were inoculated into the peritoneal cavity of ddD strain male mice of 25 g body weight. On the eighth day after inoculation, all the animals were given an intraperitoneal injection of 25 µc. of tritiated thymidine. Experimental animals were put into the chamber and high pressure oxygen was introduced. The animals were exposed to high pressure oxygen for about 50 min and then were killed exactly 60 min after the injection of tritiated thymidine. Ascites cells were collected and the specific activity of DNA was measured by the same method as before.

Table 1. EFFECTS OF EXPOSURE TO HIGH PRESSURE OXYGEN AND NITROGEN ON THE INCORPORATION OF TRITIATED THYMIDINE INTO DNA OF THE ASCITES HEPATOMA CELLS *in vitro*

	Specific activity (c.p.m. × 10 <sup>-3</sup> /mg DNA)	Per cent of control
Control (in air)	301	100
Oxygen, 1 atmosphere	371	123
Oxygen, 3 atmospheres	363	121
Oxygen, 5 atmospheres	365	121
Nitrogen, 3 atmospheres	317	105
Nitrogen, 5 atmospheres	293	97

Cells were incubated for 30 min at 37° C with 1 µc./ml. of tritiated thymidine under different atmospheric conditions. Mean of two experiments.

Table 2. EFFECTS OF EXPOSURE TO HIGH PRESSURE OXYGEN ON THE INCORPORATION OF <sup>14</sup>C-THYMIDINE AND TRITIATED URIDINE INTO DNA AND RNA OF THE ASCITES HEPATOMA CELLS *in vitro*

	<sup>14</sup> C-TMP incorp. (c.p.m. × 10 <sup>-3</sup> /mg DNA)	Per cent of control	<sup>3</sup> H-UMP incorp. (c.p.m. × 10 <sup>-3</sup> /mg RNA)	Per cent of control
Control (in air)	329	100	184	100
Oxygen, 3 atmospheres	409	124	189	103
X-ray (in air), 2,000 r.	257	78	190	103
Oxygen, 3 atmospheres, X-ray, 2,000 r.	260	79	199	105
X-ray (in air), 4,000 r.	260	79	187	99
Oxygen, 3 atmospheres, X-ray, 4,000 r.	196	60	171	91

After irradiation in air or under high pressure oxygen at 3 atmospheres, cells were incubated under the same atmospheric conditions in the presence of 0.1 µc./ml. of <sup>14</sup>C-thymidine and 1.0 µc./ml. of tritiated uridine for 30 min at 37° C.

Mean of two experiments.

Table 3. EFFECTS OF BREATHING HIGH PRESSURE OXYGEN OR IRRADIATION UNDER HIGH PRESSURE OXYGEN ON THE INCORPORATION OF TRITIATED THYMIDINE INTO DNA OF EHRlich ASCITES TUMOUR CELLS *in vivo*

	Specific activity (c.p.m. × 10 <sup>-3</sup> /mg DNA)	Per cent of control
<i>a</i>		
Control (in air)	111.4	100
Oxygen, 1 atmosphere	148.3	133
Oxygen, 3 atmospheres	145.0	130
<i>b</i>		
X-ray, 1,000 r. (in air)	55.2	50
Oxygen, 1 atmosphere, X-ray, 1,000 r.	44.6	40
Oxygen, 3 atmospheres, X-ray, 1,000 r.	29.8	27

*a*, Immediately after the injection of tritiated thymidine (25 µc), animals were exposed to high pressure oxygen for about 50 min, and were killed exactly 60 min after the injection.

*b*, After irradiation under different atmospheric conditions, tritiated thymidine (25 µc.) was injected intraperitoneally and animals were left in air for 60 min and then killed.

Mean of two experiments.

The upper half of Table 3 shows the effects of exposure to high pressure oxygen on the incorporation of tritiated thymidine into DNA of Ehrlich ascites tumour cells *in vivo*. The results are in accordance with those obtained *in vitro*.

In another experiment, animals were exposed to high pressure oxygen for 30 min and a whole body irradiation of 1,000 r. was then given under the same conditions as the *in vitro* experiments except that the dose rate was 65 r./min and the distance 70 cm. After irradiation, 25 µc. of tritiated thymidine was injected and the animals were killed 60 min later. The results are shown in the lower half of Table 3. Irradiation under high pressure oxygen produced a greater inhibition of DNA synthesis as compared with irradiation in air.

Several authors have reported toxic effects of high pressure oxygen on mammalian cells both *in vitro*<sup>11</sup> and *in vivo*<sup>12-15</sup>. Regression of experimental tumours which had been exposed to high pressure oxygen was

observed<sup>12-15</sup>. High pressure oxygen may alter the state of oxygenation of ascites tumour cells, thereby producing changes in the metabolism of the cell, but the reason for, and possible significance of, the increased incorporation of radioactive precursors into DNA exposed to high pressure oxygen both *in vitro* and *in vivo* are not yet clear.

This work was partly supported by a grant from the Ministry of Education, Japan.

### Effect of Cysteine on Acetylcholine Synthesis

CHOLINE acetyltransferase (choline acetylase; acetyl-CoA: choline O-acetyltransferase, *EC* 2.3.1.6) (ChA) is a sulphhydryl enzyme responsible for the synthesis of acetylcholine (ACh) in nervous and other tissues. Early attempts to purify ChA from rat brain and calf caudate nucleus showed that this enzyme is unstable and attempts were made to protect it by addition of cysteine to the medium. It was observed, however, that high concentrations of cysteine decreased the synthesis of ACh. Similar findings were recently reported by Morris, Hebb and Bull<sup>1</sup> in Torpedo Marmorata and rabbit brain extracts. They attributed the decreased synthesis of ACh to the inhibition of ChA by cysteine. Subsequently, Morris<sup>2</sup> studied the effect of a number of sulphhydryl compounds on ChA activity. He demonstrated that their mode of action was not directly on ChA but that they acted by depletion of the acetyl-CoA in the system. We have been able to produce evidence to support Morris's suggestion that the reaction involved is a spontaneous transacetylation between acetyl-CoA and cysteine. This mechanism presumably applies to the other sulphhydryl compounds which he studied.

In our investigations, the source of ChA used was a 100,000g supernatant of homogenate of rat cerebral cortex diluted 1:30 with distilled water. ChA activity was assayed by a modification of the radioactive method of McCaman and Hunt<sup>3</sup> and the electrophoretic method described here. All cysteine solutions were prepared from the free base immediately before use and adjusted to pH 7.7 for addition to the ChA assay medium. Addition of cysteine to the assay in concentrations above  $10^{-3}$  molar produced inhibition of ACh production (Fig. 1).

To examine the reaction products in the presence of cysteine the protein was removed by trichloroacetic

Fig. 1. The formation of *S*-acetylcysteine from cysteine and acetyl-CoA in the absence (○) and presence (●) of brain extract containing choline acetyl transferase. The inhibition of acetylcholine production in the complete incubation medium (x) is also shown.

acid precipitation and the supernatant was subjected to horizontal paper electrophoresis at 500 V in formic acid, acetic acid, water (1:3:36) (ref. 4). Using an 'Atomic Accessories' paper strip scanner, three radioactive spots were observed. Cysteine was located by staining with ninhydrin. The mobilities of the various components relative to acetyl-CoA are shown in Table 1. Spot 1 could be identified as unreacted acetyl-CoA by showing its mobility to be identical to that of acetyl-CoA applied directly to the paper. Spot 4 was of identical mobility to acetyl-1-<sup>14</sup>C choline and to non-radioactive ACh stained by exposure to iodine vapour. Spot 3 showed the mobility of cysteine. Incubation of acetyl-1-<sup>14</sup>C CoA and cysteine without rat brain homogenate produced only spots 1 and 2 after electrophoresis and strip scanning, and spot 3 on ninhydrin staining.

Table 1. RELATIVE ELECTROPHORETIC MOBILITIES OF SOME COMPOUNDS STUDIED

Spot No.	Compound	Relative cathodal mobility*
1	Acetyl-CoA	1.0
2	<i>S</i> -acetylcysteine	1.3
3	Cysteine	1.7
4	Acetylcholine	2.4

The spots are numbered in order of increasing cathodal mobility.  
\* The mobility of acetyl-CoA is taken as 1.0.

The most likely position of transfer of the <sup>14</sup>C acetyl group of acetyl CoA is to the free sulphhydryl of cysteine. When acetyl CoA was incubated with  $8 \times 10^{-3}$  molar cysteine for 60 min at room temperature at pH 9.0 virtually all the radioactivity was found in spot 2 after electrophoresis. At pH 8.0 about 50 per cent of the radioactivity was found in spot 2. The *pK* value of the sulphhydryl group of cysteine is about 8.1.

Spot 2 has a mobility different from that of *N*-acetyl cysteine stained with ninhydrin. *N*-acetyl cysteine, used in place of cysteine, inhibited ACh production in the enzyme preparation and gave rise to a radioactive spot following electrophoresis, in both the enzyme and non-enzyme incubation, different in mobility from spot 2 and presumed to be *S*-*N*-diacetyl cysteine. When cysteine was replaced by either *S*-methylcysteine or *S*-ethylcysteine, no radioactive spot other than acetyl-CoA was seen after electrophoresis of the non-enzyme incubation. These compounds did not inhibit the enzyme synthesis of acetylcholine by ChA. No radioactive spot other than acetyl-CoA and acetylcholine was seen after electrophoresis of the enzyme incubation.

It may therefore be concluded that cysteine causes apparent inhibition of ChA by consumption of the acetyl-CoA substrate by non-enzyme transacetylation. The rate of *S*-acetyl cysteine formation, both in the presence of enzyme and the complete incubation mixture, and in a mixture of acetyl-CoA and cysteine (Fig. 1), paralleled the reduction in the rate of ACh formation.

### Use of Urine to Serum Fluoride Concentration Ratios to confirm Serum Fluoride Analyses

IN 1966 I published<sup>1</sup> results showing that the normal concentration of fluoride in human serum is about one-tenth the generally accepted value—that of Singer and Armstrong. Part of the evidence supporting my results was the “at least five-fold discrepancy” that could be shown in their data<sup>2</sup> which is most easily explained by an error in the measurement of the serum fluoride. The discrepancy involves the ratio of urine to plasma fluoride concentrations when determined by fluorine-18 as compared with stable fluoride analyses. Because the concentration of fluoride in urine is well established in contrast to that in serum where analysis is much more difficult, it is reasonable to question the latter when there is a discrepancy. Singer and Armstrong<sup>3</sup>, however, in their recent rebuttal, think that I came to erroneous conclusions because I directed attention to only two of their analyses, which they now consider aberrant.

In summarizing the data as a whole they calculate that the average concentration of fluoride in the urine from one subject (C.H.C.) was 90  $\mu$ molar (1.7 p.p.m.) and from the other (W.D.A.), 179  $\mu$ molar (3.4 p.p.m.). They state that these concentrations are reasonable because I indicated that up to 150  $\mu$ molar (3 p.p.m.)<sup>1</sup> might be expected in the two samples where there was a very concentrated urine. Such a comparison completely overlooks the effect of the flow rate of urine on the expected concentration of fluoride. In the case of subject C.H.C., 1,888 ml. of urine was collected in 321 min, or 5.9 ml./min, in contrast to the 0.42 and 0.57 ml./min of the two “aberrant” samples. If the rate of flow of urine had no effect on clearance of fluoride from the blood then there would be a direct inverse relationship between concentration and rate of flow. Because the average rate of flow is increased ten-fold over the “aberrant” samples, the expected concentration in the urine for the samples as a whole would be one-tenth as much, or up to 15  $\mu$ molar (0.3 p.p.m.) rather than 150  $\mu$ molar (3.0 p.p.m.). In subject C.H.C., increasing the rate of flow twenty-fold doubled the clearance of fluorine-18, so there would be some increase in the expected concentration, but not to more than 23  $\mu$ molar (0.43 p.p.m.).

My original estimate of up to 150  $\mu$ molar (3.0 p.p.m.) fluoride for the two “aberrant” samples was based on observations<sup>4</sup> of persons drinking slightly different amounts of water than those used by Carlson *et al.*<sup>2</sup>. In order to substantiate better the expected urine fluoride concentration in the conditions used by Carlson, Armstrong and Singer, I ingested fluoride and water in the same pattern and collected 1,025 ml. of urine in 255 min or 4.0 ml./min. After thoroughly mixing the urine, five samples were analysed by Singer and Armstrong's

method<sup>5</sup> and  $21 \pm 1.5$   $\mu$ molar (0.40 p.p.m.) fluoride were found. The urine collected before any water was ingested showed  $78 \pm 8$   $\mu$ molar (1.47 p.p.m.) fluoride by the same analysis. Analysis of the same samples by my method gave mean values within 3 per cent of those analysed by Singer and Armstrong's method.

If my flow rate had been the same as that of subject C.H.C. then the urine fluoride concentration would have been lower, possibly as low as 14  $\mu$ molar (0.27 p.p.m.). Thus a four- to six-fold discrepancy exists between their calculated concentration (90  $\mu$ molar) and what I measured. This does not differ much from the “at least five-fold discrepancy” that I originally pointed out using just the two “aberrant” samples. No data on the volume of urine are given for the other subject (W.D.A.) so a comparable analysis cannot be made, but there would appear to be at least as great a discrepancy, for the concentration as calculated by Singer and Armstrong is twice as great as that for C.H.C. with the same range of urine flow rates. As indicated, the most logical explanation of this discrepancy is to assume that their serum fluoride values are in error. Certainly, they are not measuring what the kidney sees as fluoride.

There is a simple way to show what the normal serum fluoride should be in humans drinking fluoridated water. The average data for clearance of fluorine-18 for all Singer and Armstrong's samples with a flow rate of less than 2 ml./min, which involves four samples for each subject, are 56 and 49 ml. plasma cleared/min for the two subjects. If a person is excreting 50  $\mu$ molar (1 p.p.m.) fluoride in his urine at a flow rate of 1 ml./min then the plasma fluoride concentration must be 0.9–1.0  $\mu$ molar (0.018 to 0.02 p.p.m.), which is very close to the 0.7  $\mu$ molar I reported.

The inability of Singer and Armstrong<sup>5</sup> to reproduce my fusion data certainly cannot be taken as a refutation of my findings<sup>1</sup>. First, they fused sodium hydroxide rather than converting it to the carbonate-chloride salt. This makes a difference in the fusion temperature because pure sodium hydroxide fuses at 318°C while the carbonate fuses at 851°C. Second, they only examined serum from one individual and a single individual cannot be assumed to be representative of normal.

The accurate determination of the ratio of fluoride in the urine to serum by means of fluorine-18 has made it possible to confirm measurements of serum fluoride concentration of only 0.1  $\mu$ molar (0.002 p.p.m.) in pups that have been raised on a milk diet. Extension of this principle makes it possible to estimate serum fluoride concentrations as low as 0.01  $\mu$ molar, if the need should arise.

### Traumatic Acid : an Accelerator of Abscission in Cotton Explants

WE have been investigating the physiology of bud abscission induced by the feeding action of lygus bugs, *Lygus hesperus* Knight, because explants are used for biological assays<sup>1</sup>. In this bioassay, various extracts are applied in agar to the stumps of the cotyledonary petioles and the time for 50 per cent of the petioles to abscise is used for comparative purposes. In the course of these experi-

ments in which lygus bugs were fed a water extract made from lyophilized 'Kentucky Wonder' green beans, *Phaseolus vulgaris*, we discovered that the bean extract itself contained something which would greatly accelerate abscission of the explants. Many substances are known to accelerate abscission<sup>2</sup>; especially active is the plant hormone abscisin II (ref. 3). Physiologically, however, the cotton explants react quite differently to bean extract and abscisin II. With abscisin II, no well defined separation layer is formed<sup>4</sup> and little colour change occurs in the petioles before abscission. When the extract from 0.1 mg of dried beans was applied to each petiole, a pronounced separation layer was present after 24 h and the distal 3 mm of the petioles had turned brownish. (We used explants having petioles 6 mm long in contrast to the petioles 3 mm long used by Addicott *et al.*<sup>1</sup>) Abscission induced by bean extract was physiologically similar to that caused by gibberellic acid ( $GA_3$ ), in which a separation layer is formed accompanied by an increase in cell number<sup>5</sup>. With both  $GA_3$  and bean extract but not with abscisin II, a hyaline layer appeared in the abscission zone 12–24 h before the formation of the separation layer.

Fig. 1. Abscission of cotyledonary petioles of cotton explants in response to (1) traumatic acid (TA), applied at the rates of 20, 10, 5 and 1  $\mu$ g/abscission zone; (2) gibberellic acid ( $GA_3$ , 0.01  $\mu$ g/zone); (3) water extract from 0.1 mg lyophilized green beans; (4) controls (agar only); and (5) a mixture of 10  $\mu$ g TA plus 0.15  $\mu$ g indoleacetic acid (IAA) per zone.

Subtle yet significant differences exist in the reactions caused by  $GA_3$  and bean extract. Bean extract caused separation within 24 h, a browning of the distal portion of the petioles, few if any tyloses and proliferation of the cells in the protective layer after separation had occurred. After 48 h this proliferation of cells appeared as an undifferentiated cellular growth similar to callous tissue and arose from both the stump region and proximal surface of the separated petiole.  $GA_3$  induced separation after 48 h (none occurred after 24 h) but caused no browning of the petiole tips. It resulted in significant tylose formation<sup>5</sup> with no tissue growth following separation.

F. T. Addicott (personal communication) observed that these effects were like those of the wound hormone, traumatic acid (TA), which stimulates callus growth and was first isolated from 'Kentucky Wonder' beans<sup>6,7</sup>. Forty milligrams of commercially obtained TA were dissolved in 1 ml. of warm ethanol. This solution was then

mixed with 4 ml. of warm water, followed by the addition of 5 ml. of 3 per cent hot agar solution. This formed a suspension of TA in agar which was taken up in a syringe and 5  $\mu$ l. of the cooled suspension (containing 20  $\mu$ g traumatic acid) was applied to the tips of the cotyledonary petioles. Appropriate dilutions were made to yield concentrations of 20, 10, 5 and 1  $\mu$ g/abscission zone. Each concentration was tested at least three times using a minimum of twenty explants/concentration. The results (Fig. 1) show that all concentrations tested, except 1  $\mu$ g/zone, accelerated abscission in comparison to the controls. Ten micrograms of TA/zone accelerated abscission about as much as 0.01  $\mu$ g of  $GA_3$ . The abscission accelerating effects of TA can be significantly reduced by including 0.15  $\mu$ g of indoleacetic acid (IAA)/abscission zone (Fig. 1). A histological examination of paraffin sections stained with safranin fast green revealed no detectable difference between petioles treated with TA or bean extract. With TA, the first cellular changes associated with abscission were detected after 18 h, a slight amount of separation was evident at 24 h and separation was usually completed by 48 h.

### Specificity of the Kober Reaction

THE specificity of the Kober<sup>1,2</sup> reaction for oestrogen assay has been studied as part of a general investigation of the mechanisms of steroid acid colour reactions. Exactly what constitutes a positive Kober reaction has never been defined; in this work, a Kober positive steroid is regarded as one which produces pink chromogen absorbing maximally in the 500–555 m $\mu$  region by the Brown<sup>3,4</sup> or Itrich<sup>5</sup>–Bradshaw<sup>6</sup> procedures. This chromogen we have designated  $\chi_4$  because at least three other chromogens absorbing at shorter wavelengths are produced by the Kober reaction with various oestrane derivatives. On this basis, from a study of 116 relevant steroids, the following features of the steroid molecule were found to be simultaneously necessary if the steroid is to give a positive Kober reaction. An oxygen function (carbonyl or hydroxyl) is essential at either C16 or C17 and is permissible at both. The only exceptions are the  $\Delta^{16}$ -steroid discussed later and 16-oxoestrone; oestrone-16 is only feebly positive. Of the fifteen possible combinations of oxygen function at C16 and/or C17, thirteen have been tested and all except the two just mentioned are strongly positive and give a pink chromogen with  $\epsilon_{\max}$  of 30,000 to 60,000.

The oestrogen with a C16–C17 double bond and no ring D oxygen function is strongly positive, but if ring D is saturated and possesses no oxygen function the oestrane derivative is Kober negative. This supports Boscott's<sup>7</sup> suggestion that the mechanism of the reaction involves dehydration at the C16–C17 positions as the initial step.

If this is accompanied by protonation and rearrangement of the double bond and angular methyl group at C13, as has frequently been observed with steroids reacting in acidic conditions<sup>8</sup>, a carbonium ion is produced which is capable of undergoing resonance by a hyperconjugation which involves several adjacent tertiary carbon sites and is represented by structure I.

An oxygen function (hydroxyl or methoxyl) must be present in ring A.

The steroid must possess an aromatic ring A. Androstane derivatives with a saturated ring A are Kober negative. Provided there is a C17 oxygen function in the molecule, 19-norandrogens with 4-en-3-one groups are feebly Kober positive, while androsta-1,4-dien-3-ones are strongly positive. It is suggested that the latter compounds undergo the dienone-phenol rearrangement, the 19-norandrogens dehydrogenation at C1-C2 and then rearrangement to the phenol structure. Experimental support for this theory has been obtained by measurements in the ultra-violet region.

Absence of the angular methyl group at C13 does not block the first stage of reaction—formation of the yellow chromogen  $\chi_3$ , which absorbs maximally at 450–500 m $\mu$ —but the conversion of  $\chi_3$  to  $\chi_4$  in the second stage is inhibited in the absence of the methyl group.

A yellow chromogen ( $\chi_2$ ) absorbing in the region 400–440 m $\mu$  is frequently formed as a product of the Kober reaction and appears to be derived from  $\chi_3$  as an alternative to its conversion into  $\chi_4$ .  $\chi_1$  is a chromogen absorbing at 350–370 m $\mu$  formed at either stage of either procedure from some of the oestrane derivatives examined.

### Artefact of Hydrolysis of Glucosamine Derivatives

AN unusual amino sugar derivative has been reported in acid hydrolysates of the cell wall of *Penicillium notatum*<sup>1,2</sup>, and we report here the isolation of an apparently identical compound in acid hydrolysates of pure *N*-acetyl glucosamine.

*N*-acetyl glucosamine (100 mg) was heated in 10 ml. of 4 normal hydrochloric acid at 100° C for 20 h in a silicone greased, evacuated hydrolysis tube. The material

remaining after hydrolysis was recovered by evaporation of the centrifuged solution over phosphorus pentoxide and potassium hydroxide in a vacuum desiccator previously purged with nitrogen. This procedure is identical to that described for hydrolysis of the cell walls of *P. notatum*<sup>2</sup>.

Chromatography of the product on Whatman 3 MM paper using *n*-butanol, acetic acid and water (4:1:5) showed traces of a compound at an *R* glucose value of 1.65. After chromatography the area corresponding to this spot was eluted and just less than 1 mg of material was isolated. The compound gave a positive reaction to the silver nitrate<sup>3</sup>, aniline phosphate<sup>4</sup>, ninhydrin and Elson-Morgan sprays<sup>4</sup>, had the same *R* glucose values in *n*-butanol, pyridine and water (6:4:3) as the previously reported compound, and co-chromatographed with it in *n*-butanol, acetic acid and water (4:1:5) and *n*-butanol, ethanol and water (4:1:1).

Acid hydrolysis of the compound in 2 normal hydrochloric acid at 100° C gave glucosamine, identified as described before<sup>1,2</sup>. *N*-acetylation of the compound gave an *N*-acetyl derivative which co-chromatographed with the previously reported *N*-acetylated derivative in *n*-butanol, acetic acid and water (4:1:5) and *n*-butanol, ethanol and water (4:1:1).

An apparently similar compound can be detected in acid hydrolysates of lobster chitin and of the chitinous cell walls of *Penicillium roquefortii* and *Penicillium patulum*, but whereas it is produced in easily detectable amounts from the cell walls of the *Penicillium* species only traces can be produced from the other sources, including *N*-acetyl glucosamine.

The amino sugar derivative previously reported is therefore probably an artefact of acid hydrolysis of *N*-acetyl glucosamine or its derivatives. The extreme acid lability of the compound may mean that the aniline phosphate and Elson-Morgan reactions are spurious and caused by acid hydrolysis to glucosamine. No structural data are available on the small amounts of materials isolated. The compound is being described because other workers may detect it in hydrolysates of glucosamine containing polysaccharides.

We thank the Medical Research Council of Canada for a grant.

### Role of Cyclic 3',5'-Adenosine Monophosphate in the Release of Growth Hormone *in vitro*

CYCLIC 3',5'-adenosine monophosphate (3',5'-AMP) may be involved in the synthesis or release of several hormones. Corticotropin increases the concentration of cyclic 3',5'-AMP in adrenal cortex<sup>1</sup>, and cyclic 3',5'-AMP stimulates the synthesis of adrenal corticosteroids<sup>2</sup>. Luteinizing hormone increases the concentration of cyclic 3',5'-AMP in beef corpus luteum<sup>3</sup>, and cyclic 3',5'-AMP stimulates the synthesis of progesterone<sup>4</sup>. Theophylline (1,3-dimethyl-xanthine), which increases the intracellular concentration of cyclic 3',5'-AMP by inhibition of cyclic nucleotide diesterase<sup>5</sup>, increases the secretion of insulin *in vivo*<sup>6</sup>. Glucagon and epinephrine, which may affect the rate of synthesis of cyclic 3',5'-AMP<sup>7</sup>, also influence the release of insulin<sup>8</sup>. The suggestion that cyclic 3',5'-

AMP participates in the release of other peptide hormones<sup>6</sup> led me to investigate the effects of theophylline, epinephrine and glucagon on the release of growth hormone *in vitro*. I have already described a system for the study of the release of growth hormone using radio-immunoassay<sup>10</sup>.

Pituitary glands were obtained from heifers within 5 min of the death of the animal. The diaphragma sellae was dissected from the pituitary and the posterior lobe and the stalk removed. The anterior lobe was washed at 37° C in bicarbonate buffered salt solution<sup>11</sup> which had been gassed with a mixture of oxygen and carbon dioxide (95:5) and which contained bovine plasma albumin (2 mg/ml.) and glucose (1 mg/ml.), and sectioned in a Stadie-Riggs microtome. Slices were washed, and incubated at 37° C in 20 ml. of the same medium during transfer to the laboratory. They were then divided along the mid-line (so that one half served as a control for the other) and incubated with shaking in 5 ml. bicarbonate medium at 37° C for 30 min. The slices were then transferred to 5 ml. bicarbonate medium containing either epinephrine (200 µg/ml.), glucagon (5 µg/ml.) or theophylline (6.7 mmolar), and incubated with shaking at 37° C for 2 h. At intervals of 30 min, 100 µl. samples were removed and diluted in 10 ml. of phosphate buffer (40 mmolar phosphate, pH 7.4) containing albumin (1 mg/ml.) and thiomersal (0.25 mg/ml.). Growth hormone concentrations were determined by immunoassay<sup>10</sup>.

Table 1. EFFECT OF GLUCAGON, EPINEPHRINE AND THEOPHYLLINE ON THE RELEASE OF GROWTH HORMONE

Medium	30 min	60 min	90 min	120 min
Glucagon (5 µg/ml.)	—	103 ± 7%	—	107 ± 7% (11)
Epinephrine (200 µg/ml.)	—	94 ± 22%	—	86 ± 16% (8)
Theophylline (6.7 mmolar)	137 ± 8%*	140 ± 10%*	124 ± 6%*	122 ± 7% (35)†

Slices were incubated in 5 ml. bicarbonate buffered medium containing bovine plasma albumin (2 mg/ml.) and glucose (1 mg/ml.). The output in the presence of glucagon, epinephrine or theophylline was expressed as a percentage of the output by the paired control slice, and the mean and standard error are given. Figures in parentheses give the number of slices: five to six slices were obtained from each pituitary.

\*  $P < 0.001$ .

†  $P < 0.01$ .

As shown in Table 1, glucagon and epinephrine did not alter the rate of output of growth hormone, but theophylline increased the rate significantly ( $P < 0.001$ ). The mean stimulation by theophylline (31 per cent) was of similar magnitude to the stimulation observed in this system with hypothalamic extracts<sup>10</sup>. These data suggest that release of growth hormone is stimulated by cyclic 3',5'-AMP, and that pituitary  $\alpha$ -cell adenylyl cyclase is not stimulated by either glucagon or epinephrine. Stimulation of adenylyl cyclase is a possible mechanism for the effect of the hypothalamic growth hormone releasing factor.

This work was supported by a grant from the British Diabetic Association to Professor P. J. Randle whom I also thank for advice.

## Effect of $\gamma$ -Rays on the Action of an Enzyme

LITTLE is known about the effects of high energy radiation on the mechanism of enzyme action. Charlesby<sup>1</sup> investigated the decrease of activity of alcohol dehydrogenase irradiated with  $\alpha$ - and  $\gamma$ -rays and found a relatively high resistance. We have been interested, however, in the effects on the reaction of enzymes such as alterations in reaction rates, specificity and structure of products. We chose to use dextran sucrose because this enzyme is available in relatively pure preparations<sup>2</sup> and its reaction mechanism is well known from this kind of kinetic work<sup>3</sup>. It is of advantage that dextran sucrose catalyses a poly reaction and the values of the molecular weights of the products are a further parameter of the reaction. Dextran sucrose from *Leuconostoc mesenteroides* B 512F has been used, converting sucrose into fructose and high polymer dextran. The irradiations were carried out with a cobalt-60 source of about 20,000 c. First results showed that the radiation resistance of the enzyme depends a great deal on the purity of the preparation. In our experiments the enzyme concentration was between 12 and 50  $\mu$ /ml. and irradiation usually lasted for 1 h.

The decrease in the activity of the enzyme in relation to the dose of irradiation is shown in Fig. 1. The resistance of the enzyme is very high, 800 krad being necessary for a 50 per cent reduction of activity, and the enzyme is completely destroyed by 2.5 Mrad. Because of the high radiation resistance we were able to use a convenient range of radiation doses.

In the first series of experiments, we studied the dependence of the reaction rates at different substrate concentrations (5, 10 and 15 per cent) and doses of irradiation. In all cases a decrease in the reaction rate was observed with an increase in the dose of irradiation. At low substrate concentrations and with small doses of radiation the reaction is more strongly inhibited in relation to the deactivation of the enzyme. With higher doses of radiation, however, the reverse effect was observed (Fig. 1). It is interesting that the reaction rate of the dextran formation in the 15 per cent substrate solution is faster than in the solutions of lower concentrations. In our next experiment, we determined the reaction rate with and without irradiation (Fig. 2). A 5 per cent substrate solution was used and enough enzyme was added for a 100 per cent conversion within 3 h. The reaction took place under irradiation for the first and the third half hour, and in these periods the reaction rate was depressed. In the intervals without irradiation, however, the reaction rate was about as fast as in the blank experiments.

The results of all our experiments can be explained by the reaction mechanism of the enzyme we proposed earlier<sup>4</sup>. In this mechanism the dextran chain is propagated by an insertion type poly reaction. The enzyme and the growing chain form a relatively stable complex. Within one growing cycle the substrate reacts bifunction-

Fig. 1. Substrate concentrations: 4, 15 per cent; 3, 5 per cent; 2, 10 per cent. 1, Enzyme activity.

Fig. 2. 1, First radiation period; 2, second radiation period.

ally with this complex forming a Michaelis complex. The latter reacts with liberation of a molecule of fructose and the polymer chain adjacent to the enzyme is lengthened

where  $S$  is sucrose,  $F$  is fructose,  $E$  is enzyme and  $P_n$  is polymer dextran.

Considerations of the molecular mechanism<sup>4</sup> indicated that for the stability of the complexes the polymer chain must be connected to the enzyme at several sites along the chain. In pure enzyme preparations the free form exists. We assume that the adjacent polymer chain has a stabilizing influence and increases the resistance of the enzyme to radiation. The other results can be explained if the Michaelis equilibrium (1) is displaced in the direction  $EP_n + S$ . In this case the maximum rate is then reached only at higher substrate concentrations and an increase of the rate would be expected within a range in which the non-irradiated reaction is already at a maximum. Displacement of equilibrium can also be the reason for the strong inhibition with low radiation doses, for this effect would be expected to be bigger at lower substrate concentrations. This agrees with our experiments. Similarly, the experiments with the alternating irradiation periods can be interpreted as follows. The concentration of the  $ESP_n$  complex is decreased by the irradiation and therefore also the reaction rate ( $v = k_2 [ESP_n]$ ).

The interaction of the radiations on the Michaelis complex which affect the displacement of the equilibrium are not easy to interpret. Possibly oscillations of rather slow frequencies are induced by the irradiation with the result that the substrate molecule cannot be so strongly attached to the enzyme complex. The Michaelis complex then loses stability in favour of the enzyme complex. With this model the protection effect of the adjacent chain can be understood because the polymer chain is a stabilizing factor of the secondary structure of the enzyme.

If all this is true then radiation can also affect the secondary structure of enzymes, causing alterations in the elementary steps in the reaction. Such effects would lead to a fully reversible inhibition, which cannot be explained by changes in the primary structure of enzymes.

## New Pyrimidine Pathway involved in the Biosynthesis of the Pyrimidine of Thiamine

OUR studies with mutants of *Salmonella typhimurium* LT2 have revealed that the pyrimidine moiety of thiamine is synthesized by a new biosynthetic route using intermediates from the purine biosynthetic pathway. Radioactive labelling has indicated that the conventional nucleic acid pyrimidine biosynthetic pathway is not used for biosynthesis of the pyrimidine of thiamine. David, Estramareix and Hirshfeld<sup>1</sup> showed that <sup>14</sup>C-formate was incorporated into the C-4 of the pyrimidine moiety of thiamine while the C-4 of nucleic acid pyrimidines was derived from aspartate. Moreover, neither <sup>14</sup>C-aspartate nor <sup>14</sup>C-uracil, which are precursors of nucleic acid pyrimidines, was incorporated into the pyrimidine of thiamine<sup>2,3</sup>.

The finding of the new pyrimidine pathway originated with the isolation and study of single site mutants of *S. typhimurium* LT2 which had a double growth requirement for a purine plus the pyrimidine moiety of thiamine (called ath mutants in distinction from simple purine requirers called Ad mutants). Such ath mutants have been previously used in genetic studies by Yura<sup>4</sup>. A study of the distribution of ath and Ad mutants in relation to the purine biosynthetic pathway revealed that all non-leaky mutations before aminoimidazole ribonucleotide (AIR) were ath mutants and, except for one group, all mutations after AIR were Ad mutants. The mutants of the exceptional ath group, which were blocked after 4-aminoimidazole-5-carboxamide ribonucleotide (AICAR) and which seemed identical to the mutants of the ath B group in the classification of Yura<sup>4</sup>, were shown, however, to be only phenotypically like ath mutants. The ath-like character seemed to result from the production of an inhibitor of pyrimidine moiety biosynthesis. If this inhibitor was washed free they formed large amounts of the pyrimidine until the inhibitor again accumulated.

The location of all true ath mutations on the purine pathway was therefore prior to AIR and this suggested the hypothesis that the early part of the biosynthetic pathway of the pyrimidine moiety of thiamine might be common to the early part of the purine biosynthetic pathway and that AIR was the last common intermediate.

Confirmation of this hypothesis was obtained from <sup>14</sup>C-labelling experiments. Using a mutant of *S. typhimurium* LT2 which, because of its inability to join the pyrimidine and thiazole moieties of thiamine, excreted the pyrimidine moiety into the medium, it was found that radioactivity from both carbon atoms of glycine was incorporated into the pyrimidine moiety. When experiments of this sort were done with mutants which were also auxotrophic for glycine, then pyrimidine moiety biosynthesis was strictly dependent on the presence of added glycine, and <sup>14</sup>C was incorporated from both carbon atoms of glycine with little or no dilution of specific activity. This indicated that, just as for purine biosynthesis, both carbon atoms of glycine were directly incorporated into the pyrimidine of thiamine.

The hypothesis was also confirmed by finding that the ribonucleoside form of AIR (AIR<sub>s</sub>) could satisfy both the requirement for a purine and the pyrimidine moiety of thiamine in an ath mutant. Normally, purine intermediates excreted by mutants (with the exception of 4-amino-5-imidazole carboxamide) cannot be re-utilized for purine synthesis by mutants blocked earlier on the purine pathway<sup>5</sup>. An ath mutant was isolated, however, which was able to use AIR<sub>s</sub> (rigorously purified) in place of its purine and pyrimidine moiety requirements. The AIR<sub>s</sub>, moreover, removed the glycine requirement for pyrimidine synthesis for derivatives of this mutant which require glycine.

The final test of the hypothesis was the conversion of <sup>14</sup>C-labelled AIR<sub>s</sub> to labelled pyrimidine moiety. A mutant able to use AIR<sub>s</sub> and which also excreted the

Fig. 1. Simplified scheme of the purine biosynthetic pathway showing the proposed branch leading to the pyrimidine moiety of thiamine. PRPP, 5-phosphoribosyl-1-pyrophosphate; AIR, 4-aminoimidazole ribonucleotide; AICAR, 4-amino-5-imidazole carboxamide ribonucleotide; IMP, inosine-5'-monophosphate; AMP, adenosine-5'-monophosphate; GMP, guanosine-5'-monophosphate.

pyrimidine moiety into the medium was found to convert chromatographically pure  $^{14}\text{C}$ -labelled AIR<sub>8</sub> into the pyrimidine moiety of thiamine with virtually no dilution of specific activity. This provided strong evidence that this purine intermediate is also an intermediate in the biosynthesis of the pyrimidine of thiamine.

Thiamine, which is known to repress the overall biosynthesis of the pyrimidine of thiamine<sup>6</sup>, was also found to repress the conversion of radioactive AIR<sub>8</sub> to radioactive pyrimidine moiety. This result indicates that the thiamine repression site is localized between AIR and the pyrimidine.

It is concluded that the pyrimidine moiety of thiamine is synthesized from the purine intermediate AIR and this pathway is subject to repressive control by thiamine (Fig. 1). Although AIR<sub>8</sub> was the compound excreted and absorbed, it must have been derived from AIR (the ribonucleotide form) and we therefore suggest that AIR is the actual branch point intermediate.

### Ascorbic Acid in Steroidogenesis

THE adrenal glands contain the highest concentration of ascorbic acid of any tissue in the body. Changes in the concentrations of ascorbic acid and cholesterol are related to steroid secretion in the adrenal<sup>1</sup>. Although it has been suggested that ascorbic acid might play a primary part in steroidogenesis<sup>2</sup>, its physiological role in the adrenal has not been established.

It has been suggested that ascorbic acid has been involved in the electron transport system in porcine adrenal microsomes<sup>3</sup> as well as in the  $\beta$ -ol-dehydrogenase action in rat adrenal<sup>4</sup>. If such were the case in the *in vivo* system, one would expect ascorbic acid in the adrenal to facilitate production and release of steroid in con-

ditions in which the adrenals are stimulated. No such direct *in vivo* evidence is available at this time. On the contrary, accumulated indirect evidence points to an inhibitory role for ascorbic acid. A different and new hypothesis is offered here to explain some of the recent findings in the literature with regard to the role of ascorbic acid in steroidogenesis. Three lines of evidence support this hypothesis. The high concentration of ascorbate in the adrenal in the resting state exerts a "braking influence" on steroid biosynthesis. This inhibition is chiefly effected through the adrenal hydroxylase systems. Under the condition of adrenocorticotrophic hormone (ACTH) stimulation, the adrenal releases a considerable amount of ascorbate, thus reversing hydroxylase inhibition with resulting facilitation of steroidogenesis.

Lipscomb and Nelson<sup>5</sup>, using a rat adrenal vein cannulation method, demonstrated a temporal relationship between the release of ascorbic acid and steroids *in vivo*. They showed that ascorbic acid release precedes corticoid output, that concentrations of ascorbic acid in the adrenal vein effluent fall as steroid levels are rising and that no significant ascorbic acid release was observed in the absence of steroid release.

Studies in scorbutic guinea-pigs, in which progressive reduction of adrenal ascorbate was produced, indicated that no steroid inhibition occurred<sup>6</sup>. In fact, some transient stimulation of steroid production was noted in the early part of the deficiency state.

Rosenfeld<sup>7</sup>, using the perfused beef adrenal gland preparation, studied steroid biogenesis under conditions where the glands were devoid of ascorbic acid. The addition of ACTH to these preparations stimulated steroidogenesis in spite of lack of ascorbic acid in blood and adrenals.

Hayano *et al.*<sup>8</sup> demonstrated an inhibitory effect of ascorbate on steroid  $11\beta$ -hydroxylase of beef adrenal *in vitro*. The concentration of ascorbic acid in these preparations, however, was high. Recently, I have been able to demonstrate the same inhibitory phenomenon on this enzyme with a lesser amount of ascorbic acid<sup>9</sup>.

Cooper and Rosenthal showed that C-21 hydroxylase of beef adrenal is also inhibited by catalytic amounts of ascorbate<sup>10</sup>. This inhibition is associated with lipid peroxidation<sup>11</sup> and arachidonate reduction in phospholipid fraction of beef adrenal microsomes<sup>12</sup>.

Recent studies indicate that ascorbic acid released from the adrenal could be recovered quantitatively in the adrenal vein effluent<sup>13</sup>. The recovered compound is not ascorbic acid but other metabolic products of ascorbic acid, that is, dehydroascorbic acid or diketogulonic acid<sup>14,15</sup>.

Although the exact mechanism for the function of ascorbate is not known, it is possible that ascorbate in the adrenal may lead to rearrangement of the lipids and cholesterol esters. Ascorbate is a known catalyst for lipid peroxidation and is an inhibitor of another microsomal enzyme, gulonolactone oxidase, in rat liver microsomes<sup>16</sup>. The alteration of unsaturated fatty acid composition could conceivably lead to inhibition of steroidogenesis through alteration of steroid sulphhydryl complex ( $-\text{SH}-\text{C.M.S.}$ ) which has recently been postulated for steroid hydroxylase system<sup>17</sup>. Furthermore, it has recently been shown that addition of ACTH to the adrenal preparations of rats, sheep, and calves causes increase in free fatty acid content of adrenal<sup>18</sup>. It is tempting to suggest that in circumstances in which the availability of free fatty acids in the adrenal is increased, the production of cholesters of polyunsaturated fatty acids, which are known to be preferentially incorporated into steroids<sup>19</sup>, may predominate. In such conditions, a high concentration of ascorbic acid may prove deleterious to steroidogenesis through peroxidation of unsaturated lipids unless ascorbic acid is released from the adrenal before fatty acid accumulation.

If the hypothesis that the high concentration of ascorbate in the adrenal prevents steroidogenesis is correct

and that during stress or stimulation with ACTH the adrenal must first release the bulk of its ascorbate before stimulation can commence, with experimental intervention it may be possible to maintain high concentrations of adrenal ascorbate in the treated animal and demonstrate inhibition of steroidogenesis; this information is not available in the literature.

## IMMUNOLOGY

### N- and C-terminal Sequences of a Heavy Chain Disease Protein and its Genetic Implications

A VARIANT of myeloma has been described<sup>1,2</sup>; it is known as heavy chain disease, and is characterized by the presence of a homogeneous serum and urinary protein bearing only the antigenic determinants associated with the heavy or  $\gamma$ -chain of human IgG immunoglobulin. Five such cases have been described, but the protein of two patients, Zu<sup>1</sup> and Cr<sup>2,3</sup>, have been more extensively investigated because of the availability of material and appear to share common structural features. The proteins are symmetrical dimers, stabilized by disulphide bonds, with molecular weights in the range of 50,000–55,000. Peptide maps reveal they contain the Fc portion of the heavy chain as a chief structural unit<sup>3</sup>. This conclusion is supported by the content of carbohydrate<sup>3</sup>, the presence of Gm specificities<sup>4</sup>, and biological activities<sup>5,6</sup> of these proteins, properties also attributed to the C-terminal half of the heavy chain.

The sequences of the C-terminal octadecapeptide of a  $\gamma_{2b}$  pathological IgG immunoglobulin and normal human IgG immunoglobulin have been reported<sup>7,8</sup> as shown in Fig. 1. A C-terminal octadecapeptide of homologous but not identical sequence was established for the urinary heavy chain disease protein of the patient Zu and a 7S myeloma protein, both of the  $\gamma_{2c}$  sub-class, as shown in

Fig. 1 (refs. 9 and 10). This observation provides chemical evidence that the biosynthesis of the Zu protein proceeded to a termination which has a corollary in intact heavy chain and infers that the cistron transcribed in the biosynthesis of the C-terminal region of myeloma proteins and this variant were structurally identical.

In both Zu and Cr antigenic identity has been demonstrated between the serum and respective urinary heavy chain disease protein of each individual, and in the case of Cr Franklin<sup>3</sup> has reported similar molecular weights, amino-acid and carbohydrate compositions for both the urinary and serum heavy chain disease proteins. These observations imply that passage of the proteins through the kidney was not accompanied by detectable degradation. Furthermore the serum of Cr was shown to be devoid of unusual proteolytic activity toward normal IgG, and the half life of administered <sup>131</sup>I-IgG was within the lower normal limits in this patient<sup>3</sup>. Although no evidence of unusual proteolytic activity was observed, the possible formation of the 3-6S serum heavy chain disease protein by fragmentation of an unusually fragile 7S precursor cannot be ruled out. The presence of Fc'-like material in normal urine<sup>11,12</sup> demonstrates the *in vivo* formation of such fragments and their ability to be excreted by the kidney.

The presence of a mixed N-terminal sequence would strongly support the degradative origin of the protein, and so I have investigated the N-terminus of the heavy chain disease protein of Zu. Totally reduced and alkylated Zu protein was treated with 2,4-dinitrofluorobenzene in a solution of potassium bicarbonate and guanidine hydrochloride<sup>13</sup>. After hydrolysis of the DNP-protein in 6 normal hydrochloric acid at 110° C for 18 h only DNP-Val and DNP-Leu (0.03 mole and 0.04 mole/26,000 g of protein respectively, uncorrected) were identified in the ether soluble phase and  $\epsilon$ -DNP-lysine (7.5 moles/26,000 g of protein, uncorrected) in the water soluble phase. No DNP-cysteic acid was observed in the acid hydrolysate of unreduced dinitrophenylated Zu protein which had subsequently been oxidized with performic acid<sup>14</sup>. Because of the destruction of DNP-glycine, DNP-proline and DNP-tryptophan during acid hydrolysis, and the difficulty in identifying *bis*-DNP-histidine, the N-terminus of the Zu protein was also examined by the cyanate method as described by Stark and Smyth<sup>15</sup>. By this procedure glycine, alanine and aspartic acid (0.05 mole, 0.03 mole and 0.08 mole/26,000 g of protein, respectively) were found, as well as valine and leucine (0.04 mole and 0.08 mole/26,000 g of protein, respectively). The significance of the glycine and alanine is difficult to assess, as the artefactual formation of these amino-acids has been observed in the conditions described<sup>15</sup>. Possibly the presence of aspartic acid here represents the release of a small amount of an aspartic-glycopeptide, for dinitrophenylation had not revealed aspartic acid as an N-terminal residue. Thus it would appear that no dominant free N-terminal amino-acid residue could be established for the Zu heavy chain disease protein, nor could the N-terminus be accounted for by the summation of various N-terminal residues.

Press *et al.*<sup>7</sup> have reported the identification of a pyroglutamic acid (PCA) blocked N-terminus on the heavy chain of a  $\gamma_{2b}$  pathological human IgG immunoglobulin. The tripeptide PCA-Val-Thr was isolated from a 'Pronase' digest of the heavy chain, and this sequence has been extended using the cyanogen bromide fragments of the chain<sup>7,16</sup>. A limited heterogeneity of PCA blocked N-terminal sequences also have been identified on the heavy chain of normal rabbit IgG immuno-

globulin<sup>17</sup>, which include PCA-Glu, PCA-Ser-Leu and PCA-Ser-Val. The Zu heavy chain disease protein was examined for a blocked N-terminus in the same manner as described by Press *et al.*<sup>7</sup> for their immunoglobulin and by Ikenaka, Bammerlin, Kaufmann and Schmid for orosomucoid<sup>18</sup>. A 'Pronase' digest of 50 mg of totally reduced and alkylated Zu protein was run down a column of 'Dowex 50' ( $\times 2$ ; H<sup>+</sup> form), and the unabsorbed peptides eluted with water; the eluate was concentrated and subjected to high voltage paper electrophoresis at pH 3.5. A ninhydrin stain was negative, but staining by the hypochlorite/starch-iodide technique revealed a neutral and an acidic band, the latter of which migrated with a mobility of 0.70 relative to synthetic PCA-Val used as a marker. Both bands were eluted, hydrolysed and analysed on the amino-acid analyser. The neutral band was found to contain aspartic acid, threonine, serine and hexosamine, and probably represented a glycopeptide. The acidic band contained glutamic acid and valine in a molar ratio of 1.97 to 1.00; the yield of tripeptide at this stage was 0.6 mole/26,000 g of Zu heavy chain disease protein. The acidic peptide was digested with carboxypeptidase A at pH 8.0 overnight at 25°C, and the digest electrophoresed on paper at pH 6.5. The hypochlorite/starch-iodide stain revealed an acidic and a neutral band, but only the neutral band gave a positive staining reaction with ninhydrin. On hydrolysis only glutamic acid was found in the neutral band, which therefore must have been present as glutamine in the original tripeptide. The acidic peptide possessed the same mobility as the synthetic PCA-Val marker when subjected to high voltage paper electrophoresis at pH 6.5, 3.5 and 1.9 and the same  $R_F$  on paper chromatography in butanol-acetic acid-water (4:1:5), and on hydrolysis and analysis yielded glutamic acid and valine in equimolar quantities. Hydrazinolysis of the dipeptide released only valine, establishing the N-terminus of the Zu heavy chain disease protein as PCA-Val-Gln. This same tripeptide has been identified as the N-terminus of one, and only one, of the fragments obtained by cyanogen bromide cleavage of the Zu protein.

It seems unlikely that this unique N-terminal sequence should arise from enzyme degradation of a precursor molecule, because this would predicate the selective cleavage leading to the new N-terminal glutamic acid or glutamine residue with subsequent cyclization to PCA. But obviously this possibility cannot be excluded. In view of the close homology to the N-terminus reported for a pathological human IgG (Fig. 2A) and the recent report

that 20–40 per cent of the IgG molecules of pooled normal human serum have the N-terminal sequence PCA-Val-Glu(NH<sub>2</sub>) on the heavy chain<sup>19</sup>, a more intriguing interpretation suggests itself. Perhaps, following the site of initiation of the  $\gamma$  chain, the cistron corresponding to the chief portion of the Fd area of the chain has been deleted, biosynthesis recommencing in the Fc area of the chain (Fig. 2B). The deletion of the Fd area and the heavy-light disulphide bond may partly account for the lack of light chain associated with the heavy chain disease protein, the persisting unutilized light chain suppressing the further production of light chain such that no significant quantity of circulating free light chain is observed. An alternative hypothesis has been put forth by Askonas and Williamson<sup>20</sup> proposing the transposition of the initiation site to a new position in the interior of the cistron by a mutation which permits an internal codon to be read as an initiator codon (Fig. 2C). A distinction between these alternatives may be possible if an extended homology of the N-terminal sequence of the Zu heavy chain disease

protein and 7S myeloma can be established, and a switch point to the Fc structure identified.

I thank Professor R. R. Porter for advice and Professor E. F. Osserman for his interest as well as gifts of the Zu protein. This work was supported in part by a US Public Health Service Fellowship.

## PATHOLOGY

### Metabolism of Tritium Labelled Dopamine in Schizophrenic Patients

THE metabolism of dopamine has been of interest in research on schizophrenia since Friedhoff and Van Winkle<sup>1</sup> announced that they had found 3,4-dimethoxyphenylethylamine (DMPEA) in the urine of schizophrenic patients but not in the urine of normal persons.

In 1963 they<sup>2</sup> administered labelled dopamine, the presumed precursor of DMPEA, to schizophrenic patients and reported that they found DMPEA, and 4-hydroxy-3-methoxyphenylethylamine and the two corresponding acetic acids excreted in the urine.

Later investigations<sup>3,4</sup> have, however, shown that their original method for identification of DMPEA was not specific. Several substances such as *p*-tyramine<sup>5</sup>, bacterial intestinal products<sup>6</sup> and drug metabolites<sup>4</sup> may interfere with the identification of DMPEA in the different analytical methods.

This uncertainty has led us to infuse tritium labelled dopamine in schizophrenic patients in the same way as Friedhoff and Van Winkle in order to study the metabolic conversion of dopamine.

The material consists of one normal control and four chronic schizophrenic patients, whose main symptoms were severe withdrawal, hallucinations and delusions. They had all been in hospital for many years and were on maintenance therapy with phenothiazines. The treatment was stopped 22–80 days before the investigation.

The patients were in bed and fasting during the investigation. At 9 a.m. they voided and labelled dopamine dissolved in 10 ml. of physiological sodium chloride solution was injected intravenously, the injection time being 2.5 min. Immediately after the injection they drank 400 ml. water. The urine produced for the next 3 h was collected.

The injected dopamine was 3,4-dihydroxyphenylethyl-2-<sup>3</sup>H-amine, specific activity 1.84 c/mmol. The amount injected was 176  $\mu$ C. dopamine-<sup>3</sup>H + 0.0146 mg dopamine.

The collected urine samples were investigated for the following acids: 3,4-dimethoxyphenylethylacetic acid (DMPAA), homovanillic acid (HVA) and vanilmandelic acid (VMA), and for the following amines: 3,4-dimethoxyphenylethylamine (DMPEA), 4-hydroxy-3-methoxyphenylethylamine (HMPA) and normetanephrine (NM).

One sixth of the collected urine was used for estimation of the acids, and to this part of the urine was added unlabelled carrier material: 600  $\mu$ g of DMPAA and HVA, and 300  $\mu$ g of VMA.

The acids were isolated on paper chromatograms as described by Armstrong *et al.*<sup>7</sup>. The spots were localized by scanning in shortwave ultra-violet light, cut out and extracted with ethanol and the amount of tritium in the extract was estimated in a liquid scintillation counter. To the rest of the urine which was used for the estimation of the amines 250  $\mu$ g of unlabelled carrier substance of each of the three amines were added.

The occurrence of the amines was investigated in both hydrolysed and unhydrolysed urine. The urine samples were subjected to three fractionations following each other: chromatography through a 'Dowex' column, one way paper chromatography of eluates from the column and two way thin-layer chromatography of eluates of the spots on the paper chromatogram as described by Faurbye and Pind<sup>8</sup>.

The thin-layer chromatograms were developed by ninhydrin spraying, the spots with the three amines were scraped off and extracted with ethanol, and the tritium content of the ethanol solution estimated in the liquid scintillation counter.

The recovery of the amines was between 64 and 86 per cent, and the values in Table 1 are corrected to 100 per cent recovery. The method allows estimation of labelled substances containing about 0.06 parts per thousand of administered tritium in both hydrolysed and unhydrolysed urine.

Table 1 shows that there is no difference between the control and the schizophrenics. The excretion of DMPEA, if any, must have been less than 0.06 parts per thousand of the administered labelled material.

The radioactivity extracted from the DMPAA spots was so slight that it was significant in only two of the schizophrenics. Whether this weak radioactivity was

caused by DMPAA or another substance at the same place in the chromatogram is not known.

The obtained pattern of dopamine metabolites indicates that the main metabolite of dopamine is HVA (4-hydroxy-3-methoxyphenylacetic acid), and it seems likely that the DMPAA found in our experiment was formed by 4-methoxylation of HVA. Friedhoff and Van Winkle<sup>1,2</sup> have suggested that there is another pathway through DMPEA to DMPAA. The occurrence of dimethoxylation has been confirmed by Kuehl *et al.*<sup>9</sup>, who demonstrated the presence of DMPAA in both schizophrenic and normal urine in about equal amounts.

## Carcinogenicity of the Herbicide Maleic Hydrazide

MALEIC hydrazide, 1,2-dihydropyridazine-3,6-dione, was synthesized in 1947 (ref. 1) and has since become an important herbicide with uses including inhibition of sprouting in vegetables and stored root crops, prevention of sucker production in tobacco plants and growth control of grass, and foliage<sup>2</sup>. Maleic hydrazide is claimed to be selectively toxic to plants but not to bacteria, fungi, rodents or dogs<sup>3</sup>; it is, however, mutagenic to *Drosophila melanogaster*<sup>4</sup> and *Bacillus megatherium*<sup>5</sup>, it reduces the fertility of pea aphids<sup>6</sup>, and produces cytotoxicity, mitotic inhibition and unbalanced growth in cultured mammalian cells<sup>7</sup>. The finding that maleic hydrazide induced breakage of heterochromatin besides mitotic inhibition in *Vicia faba*<sup>8</sup> prompted this warning: "Since nearly all chromosome-breaking agents have so far proved to be cancer-producing as well, we must hope that the agricultural use of this new agent will not be encouraged before suitable tests are made." Later tests claimed to show that maleic hydrazide is non-carcinogenic<sup>9</sup>. This conclusion seems at variance with the data on which it was based; for example, after weekly injections of 5 mg of maleic hydrazide as the diethanolamine salt during 14 months, an "unusually high" incidence of local sarcomas, in three out of fifty-two rats at risk with none in controls, was noted<sup>9</sup>. In other experiments, a total of 260 mg of maleic hydrazide in arachis oil was injected subcutaneously during 65

weeks, and three local sarcomas, one with a hepatoma, developed in three of six rats; it was concluded that the herbicide was clearly carcinogenic<sup>10</sup>.

We report here a high incidence of remote tumours, hepatomas, after subcutaneous injections of maleic hydrazide in infant mice. Swiss mice (*ICR/Ha*) were injected subcutaneously with aqueous solutions or tricapylin suspensions of maleic hydrazide as the free acid, batch No. Q5199 containing about 0.4 per cent hydrazine as an impurity, or with solvent in volumes of 0.1, 0.1, 0.2 and 0.2 ml. at 1, 7, 14 and 21 days following birth, respectively. (MH is the usual commercial formulation marketed by US Rubber and is stated to contain 42 per cent inert ingredients and 58 per cent diethanolamine salt of maleic hydrazide, equivalent to 30 per cent of this herbicide. MH-30 contained about 0.07 per cent hydrazine with respect to maleic hydrazide.) Results are shown in Table 1. Details of injection techniques, animal care and autopsy procedures have been described before<sup>11,12</sup>. Of the mice, 97 per cent based on numbers at risk at weaning were autopsied; the remainder were autolysed or cannibalized. Experiments stopped when mice reached 49–51 weeks old (49+).

Mortality before weaning was generally limited to the first 3 days of life and was high after injections of 5 or 10 mg of maleic hydrazide on day 1, 55 per cent and 100 per cent respectively, in contrast with controls, 14 per cent (Table 1). After weaning, substantial sex differences in survival developed because of a non-specific syndrome of obstructive uropathy the incidence of which, based on numbers of males alive at weaning and subsequently autopsied, was high in all groups. In controls it was 38 per cent, and 57 per cent and 52 per cent respectively in groups given 3 and 55 mg of the herbicide. Relative to controls, there was evidence of limited weight loss (about 5 per cent) in mice at 49+ weeks in the maleic hydrazide suspension group.

Numerous hepatomas were noted at the termination of experiments in males receiving a total dose of 55 mg of maleic hydrazide compared with controls; the incidences of hepatomas, based on mice alive at 49+ weeks, are 73 per cent for the suspension of maleic hydrazide versus 8 per cent for the solvent controls (Table 2). These differences are very significant, continuity-corrected  $\chi^2 = 24.27$ ,  $P < 0.000001$ ; analysis of variance to take possible litter influences into account, because tumours were not randomly distributed between various litters, yields similar significance,  $F(1, 23) = 33.86$ ,  $P < 0.00001$ . The hepatomas were solitary or multiple, ranging in size from the microscopic to larger than the normal liver, and were generally of the classical trabecular type with conspicuous hyaline

inclusion bodies. No metastases were noted. The high incidence of hepatomas in the maleic hydrazide suspension group, and to a lesser extent the lower incidence of tumours in the maleic hydrazide solution group, was associated with numerous atypia in the livers of the remaining non-tumour bearing male mice. These atypia featured zonal necroses and histiocytic infiltrations, nuclear and cytoplasmic inclusion bodies, increased cytoplasmic basophilia and cellular pleomorphism. If the advanced atypia, as possible pre-neoplastic lesions, are grouped with the hepatomas, then differences between test and control groups are further emphasized. Of the other tumours (Table 2), it may be noted that one fibrosarcoma developed in each of the maleic hydrazide groups in contrast with none in controls.

These data clearly indicate the high carcinogenicity of maleic hydrazide for male mice. The total dosage bringing about liver tumours in the suspension group was 55 mg; the four individual doses, of 5, 10, 20 and 20 mg, are equivalent to 2,500, 2,000, 1,000 and 667 mg/kg on days 1, 7, 14 and 21, if the corresponding animal weights are approximated as 2, 5, 10 and 15 g respectively.

While human populations in general are continuously exposed to maleic hydrazide, it is difficult to compute the level of this exposure. It can be assumed that each day an adult male ingests approximately 1.5 mg of maleic hydrazide from potatoes and onions and inhales 0.27 mg from forty cigarettes, assuming residues of 10 p.p.m. in potatoes<sup>13</sup> and onions and 132 p.p.m. in tobacco of which 6.7 per cent is found in smoke<sup>14,15</sup>. A resulting annual exposure to about 630 mg of maleic hydrazide is some twelve times greater than doses found here to be very carcinogenic. Additionally, it may be noted that because an adult man weighs about 3,000 times more than an adult mouse, on an mg/kg basis, this factor should be applied to the 55 mg of maleic hydrazide given as a carcinogenic dose to a mouse. Many drugs, however, on an mg/kg basis, are more toxic in man than mouse, generally by a factor of 10–15 (ref. 16), so that the 3,000-fold factor becomes reduced to about 200. Thus based on FDA tolerances of 50 p.p.m. (ref. 17), about five times greater than residues generally found, human ingestion of maleic hydrazide from potatoes alone would reach concentrations comparable with the dose of 55 mg carcinogenic to a mouse in about 4.5 yr. Protection in man, however, might be afforded by certain offsetting factors; much human exposure to maleic hydrazide is in the diets of children or adults, in contrast to the present experiments where suspensions of the compound were administered parenterally to infant mice. Intestinal absorption, however, seems high; after an oral dose of 100 mg/kg in rabbits, 43–62

per cent can be recovered from urine within 48 h<sup>9</sup>. The importance of the age factor is questionable, for root crops are common baby foods.

It seems unlikely that maleic hydrazide presents a high carcinogenic hazard; but the risks are the result of the ubiquity of the herbicide and the progressive exposure of entire populations. Such hazards can only be justified if applicable to very small population samples, particularly if there is justification such as unmatched therapeutic benefits. It would thus seem appropriate to reduce tolerance levels of maleic hydrazide or ban its use, except when human exposure can be minimized.

The complete absence of pulmonary carcinomas and multiple adenomas in these experiments makes it improbable that the carcinogenicity of maleic hydrazide is caused by a presumptive ring scission *in vivo* to yield hydrazine or to trace contamination with this compound which is a potent lung carcinogen in several species of rats and mice, although also hepatocarcinogenic in *CBA* mice<sup>18</sup>. We do not yet know whether the carcinogenicity of maleic hydrazide depends on modification of nucleic acid synthesis, as demonstrated in plants<sup>19,20</sup> and cultured mammalian cells<sup>7</sup> or on other unrelated mechanisms.

This work was supported by a US Public Health Service Research grant. We thank the Naugatuck Chemical Division of US Rubber for the sample of maleic hydrazide.

## CYTOLOGY

### Inhibition of DNA Synthesis of Target Cells *in vitro* by Sensitized Lymphocytes

SEVERAL experimental systems have been developed to test the cytotoxic effect of sensitized lymphocytes on target cells *in vitro*<sup>1-7</sup>. In a previous report<sup>8</sup> we presented evidence for the inhibitory effect of lymphocytes on DNA

synthesis in the target cells. Although this effect is strongest for the sensitized lymphocytes, the fact that it is also shown by the non-sensitized lymphoid cells casts some doubt as to its specificity. A further examination of this phenomenon was therefore undertaken.

The experimental methods have been described elsewhere<sup>8</sup>. Briefly, monolayer cultures were made with mouse cells of embryo or of sarcomas induced by methylcholanthrene and maintained by serial transplantation. Twenty-four to forty-eight hours later, a known number of cells from the peripheral lymph nodes of allogeneic mice sensitized by the subcutaneous inoculation of either the tumour cells or the splenic cells of normal mice were added to the target cells. Lymph node cells of untreated allogeneic or syngeneic mice served as controls. After a further 16-24 h of incubation, 0.1  $\mu$ Ci of thymidine-2-<sup>14</sup>C was added to each culture tube. The target cells, together with the added lymphocytes, were collected 4-68 h, 24 h or less in 85 per cent of experiments; after the addition of thymidine, they were washed with Hanks' salt solution, dissolved in formic acid and then dried on a planchet. Their radioactivity was measured by a thin windowed Geiger-Müller tube. The radioactivity was confined to the nuclear portion, indicating participation in the DNA synthesis by the labelled thymidine, as shown in autoradiographs prepared from parallel experiments labelled with tritiated thymidine. In prolonged incubation, there must have been some degradation of thymidine. This factor was probably insignificant in view of the continued incorporation of labelled material into cells in such cultures. Furthermore, in most of the experiments the incubation period was rather short, 24 h or less in 85 per cent and 12 h or less in 37 per cent of experiments.

The sources of allogeneic lymphocytes for (AXDBA/2)*F*<sub>1</sub> (H2<sup>a</sup>XH2<sup>a</sup>) target cells were C57BL (H2<sup>b</sup>), A.SW (H2<sup>s</sup>), ABY(H2<sup>b</sup>) and A.CA(H2<sup>f</sup>) mice, for A.CA target cells were ABY and A.SW mice, for C57BL target cells were A.CA and (AXADBA/2)*F*<sub>1</sub> mice, for ABY target cells were A.CA, A.SW and A(H2<sup>a</sup>) mice and for A target cells were ABY mice. A total of thirty-nine groups of experiments were performed. In some the target cells

Fig. 1. Inhibition indices Syn/None calculated from the radioactivities of target cells after incubation with thymidine-2-<sup>14</sup>C for various periods of time. The lymphocytes were added to the target cells 16-24 h earlier. The experiments in which the old culture medium was replaced by fresh medium is indicated by a circle.

Fig. 2. Inhibition indices Imm./All. The experiments in which the old medium was replaced by fresh medium is indicated by a circle.

were collected after incubation with thymidine for various lengths of time. Thus in such cases there were several separate experiments within the same group. There were seventy-two individual experiments. Allogeneic lymphocytes were always used, but syngeneic cells were used in only sixty-two experiments. The lymphocytes to target cell ratio varied from 2:1 to 100:1; in 67 per cent of the experiments, however, it was between 5:1 and 10:1.

Radioactivities were measured in c.p.m. In order to evaluate the specificity of the lymphocytic effect, the results were expressed in terms of inhibition indices. The inhibition index Imm./All. is calculated as follows: the radioactivity of target cells treated with sensitized allogeneic lymphocytes was subtracted from the corresponding value of target cells treated with non-sensitized allogeneic cells and divided by the latter. It indicates the effect of sensitization. The inhibition index All./Syn. is calculated from the radioactivity of target cells treated with allogeneic or syngeneic lymphocytes of normal mice and indicates the effect of histoincompatibility. The inhibition index Syn./None, using the radioactivity of untreated target cells as control, indicates the non-specific effect of syngeneic lymphocytes.

All lymphocytes, irrespective of their sources, showed an inhibitory effect on DNA synthesis in the target cells. The lymphoid cells of normal syngeneic mice exhibited the least effect. Even with these cells the inhibition was strong (Fig. 1), corresponding roughly with the duration of incubation and with the number of lymphocytes. After the old medium was replaced by fresh culture medium at the time of addition of thymidine, this inhibition was largely eliminated; in some instances the target cells treated with lymphocytes grew even better than the untreated target cells (Fig. 1), indicating an exaggerated recovery from the lymphocytic effect.

The sensitized lymphoid cells from the allogeneic mice showed the greatest inhibition. It was more pronounced than the inhibition by non-sensitized allogeneic cells in 60 or 83 per cent of seventy-two experiments (Fig. 2). In ten experiments, however, the inhibition index was 0.20 or less and in six other experiments it was between 0 and -0.20. These sixteen experiments were considered inconclusive. In six others (8 per cent of the experiments) the inhibition index was less than -0.20, suggestive of either inadequate sensitization or excessive toxicity of normal lymphocytes. In fifty experiments (70 per cent), the inhibition index was over 0.20. The percentage of positive experiments increased to eighty-six when the old culture medium was replaced by a fresh one, as was done in seven experiments. There is no apparent correlation between the inhibition indices and the duration of culture. These results might be interpreted as indicative of the effect of sensitization and a manifestation of immune reaction.

In sixty-two experiments, the radioactivity of target cells treated with allogeneic lymphocytes from normal mice was compared with that obtained with syngeneic cells. The results (Fig. 3) indicated a higher degree of inhibition by the allogeneic cells and the degree of inhibition corresponded to some extent with the duration of incubation. In thirty-six experiments (58 per cent) the inhibition indices were within the range of 0.20 and -0.20, however. In only nineteen experiments (31 per cent) were the indices over 0.20, possibly the result of histoincompatibility. The interpretation is by no means certain, however, because by changing to fresh medium this effect was eliminated.

Because the radioactivity was measured on all the cells in the same culture, part of it must be in the lymphocytes. The mouse lymphocytes did not proliferate well, however,

Fig. 3. Inhibition indices All./Syn. The experiments in which the old medium was replaced by fresh medium is indicated by a circle.

in this system, either incubated alone or with the target cells (especially in culture of long duration) and accounted for less than 5 per cent of the total radioactivity<sup>8</sup>. A significant amount of radioactivity in the lymphocytes would obscure its inhibitory effect on the target cells and this may well be the cause of the apparent lack of inhibition in some of the short term cultures.

The results of these experiments indicate a universal inhibitory effect of lymphocytes on the synthesis of DNA in the target cells. The non-specific inhibition by normal lymphocytes appears to be affected by the condition of the culture medium, whereas the inhibition by sensitized lymphoid cells appears to be cell bound. Whether the non-specific effect is the result of competition between the utilization of isotope labelled thymidine and the utilization of DNA or its derivatives released from the lymphocytes requires further investigation.

This investigation was supported by the US National Cancer Institute, the Swedish Cancer Society and the Damon Runyon Memorial Fund.

### Splitting Line of Bacterial Spore

THE mechanisms involved in the germination of bacterial spores have been studied extensively from the biochemical and morphological points of view<sup>1,2</sup>. Details of morphological changes occurring during germination, however, have not yet been demonstrated clearly. It is not known whether or not, when a new vegetative cell emerges from the spore, the spore coat splits by some specific mechanism.

During electron microscopic studies of the structure of the spore coat of *Bacillus subtilis* we found that there was a fissure on laminated layers of the spore coat. We thought that the spore coat might split at the site of the fissure, when a vegetative cell emerges.

Spores of *Bacillus subtilis* Marburg strain, collected from a nutrient broth culture, were sectioned with an ultra-microtome and observed with a JEM-7 type electron microscope. Procedure was as follows: the spores were fixed with osmium tetroxide, embedded in epoxy resin and sectioned. Photographs of the cross section are shown in Figs. 1 and 2, of which the latter shows an enlarged picture of a fissure in the laminated layers illustrated in Fig. 1.

The intact spore was slightly disrupted in a cell disintegrator with fine glass beads to remove the contents of the spore. The spore coat thus prepared retains its initial shape and is more transparent, and more clearly shows its surface structure, as compared with the intact

spore. One of such direct images of the spore coat is shown in Fig. 3, and reveals the presence of an equatorial band opaque to electrons on the surface of the spores.

Fig. 1 indicates that the spore coat is composed of three layers: a membranous outermost layer, an electron opaque outer layer, and an inner laminated layer. We think, however, that these layers are made up of essentially the same material; the difference in appearance between them seems to result from some artefact produced during fixation.

As reported before<sup>3</sup>, we have shown by electron diffraction that the spore coat lamellae of *Bacillus subtilis* are single crystals. It is also known that the spore coats of bacilli are mainly proteins<sup>4,5</sup>. These facts suggest that the spore coat which wraps the cortex and core is composed of about fifteen lamellae, and that each of the lamellae is a thin single crystal of structural protein. Each lamella is about 33 Å thick.

If this conception is correct, it seems unlikely or impossible that various kinds of organic or inorganic substances

Fig. 1. Cross section of the spore of *Bacillus subtilis*, showing the outer layer structure of the spore coat with a fissure.

Fig. 2. Enlarged picture of the fissure in the laminated layers illustrated in Fig. 1.

Fig. 3. Direct image of the partially disrupted spore of *Bacillus subtilis*. The electron opaque band is seen on the spore surface.

permeate through these crystal lamellae of the spore coat. It is, however, well known that water, amino-acids (especially L-alanine) and other substances actually penetrate into the spore core, and that dipicolinic acid is discharged from the spore in the early stage of germination. There must be therefore some passage through which these substances were carried into or out of the spore, and it seems not unreasonable to consider that the fissure of the laminated layer of the spore coat which is shown in Fig. 2 serves for the passage of these substances.

As for the swelling of the spore during germination, Rousseau *et al.*<sup>2</sup> found that an increase in volume of the spore was caused by the swelling of the cortex and core, and at the same time as these spore contents were swelling an expansive force was delivered to the spore coat. From the mechanical point of view, the part of the spore coat least resistant to this force is undoubtedly where the laminated layer is fissured. The electron opaque band, shown in Fig. 3, seems to have a ridge in the direction of the principal equator. We think that this ridge corresponds to the fissure shown in the cross section. Along this fissured and ridged line, the spore coat may split by mechanical pressure and allows the vegetative cell to emerge. Pictures resembling ours have been obtained by several investigators with spores of *Bacillus megaterium*<sup>5,6</sup>. We suppose therefore that such lines of splitting usually exist in the spores of bacteria belonging to the genus *Bacillus*.

We thank Dr Michio Oikawa, of Japan Electron Optics Laboratory Co., Ltd., for preparing the specimen. This work was supported in part by a research grant from the Ministry of Education, Japan.

## Genetic Recombination in Germinated Oospores of *Phytophthora infestans*

THE sexual process of the heterothallic fungus, *Phytophthora infestans* (Mont.) De Bary, in Mexico<sup>1,2</sup> has long been suspected of being an important source of variation in the pathogenesis of new isolates to resistant varieties of potato<sup>3</sup>. Although various investigators<sup>2-6</sup> have reported a low percentage of germination of oospores from controlled crosses in the laboratory, there is little information about the role of sexuality. In some of our experiments as much as 64.0 per cent of the oospores germinated. In this communication, we will briefly describe the variation in pathogenesis and compatibility type of progeny from single germinated oospores.

Oospores were produced by pairing strains of the fungus of different pathogenicity and compatibility type on unclarified V-8 juice agar (V-8A), clarified V-8 juice agar (CV-8A), or CV-8A fortified with  $\beta$ -sitosterol, and incubating in darkness at 18°C. Plates containing oospores were refrigerated at 4°C for between 13 and 45 days. Oospores were separated from the agar by passage through a fine plastic sieve and from mycelium by allowing the oospores to settle in water and decanting off the supernatant. Clonal cultures from single oospores germinated in double-distilled water under diffuse fluorescent light were established by incubating germ-sporangia on tomato juice (5.0 per cent)-vancomycin (200 p.p.m.)-agar (TVA)<sup>7</sup> at 20°C. Germ-sporangia germinated directly to produce germ-mycelia. The percentage germination was determined by observing 500 or more oospores/sample. The pathogenicity of thirty of these cultures was determined by inoculating foliage of differential varieties of potato, employing a detached leaf technique in Petri dishes. Compatibility type of clonal cultures was determined by crossing them with two strains of known compatibility type, 445 (A2) and 473 (A1).

The production and germination of oospores were partially dependent on the substrate, for example, more oospores were produced on V-8A than on CV-8A, but when 0.3 mg of  $\beta$ -sitosterol was added to 15 ml. of CV-8A, the number of oospores produced was as great as on V-8A.

Germination of oospores produced on CV-8A, V-8A, and CV-8A supplemented with  $\beta$ -sitosterol (0.3 mg/15 ml. of medium), exposed to light for 1 h a day for 8 days, and then refrigerated at 4°C for 13 days was 20 per cent, 30 per cent and 34 per cent, respectively. In a further experiment, 48 per cent of the oospores produced on CV-8A plus 0.45 mg of  $\beta$ -sitosterol, exposed to fluorescent light for 1.5 h daily for 8 days, and refrigerated at 4°C for 45 days germinated. In another experiment, 64 per cent of the oospores formed on V-8A fortified with 0.3 mg of  $\beta$ -sitosterol germinated.

When oospores were obtained from isolates 445  $\times$  473 or from 477  $\times$  473 grown on CV-8A plus 0.45 mg of  $\beta$ -sitosterol and refrigerated for 45 days at 4°C, approximately 48 per cent germinated, but when oospores were obtained from 60A  $\times$  63B only 6 per cent germinated. This suggests that there is probably a genetically controlled tendency for oospores from different crosses to germinate. Considering possible evolutionary processes, this sort of variation might be expected. Perhaps isolates such as 60A  $\times$  63B might produce more persistent oospores in nature than those producing readily germinable oospores. This concept warrants more study and should contribute to a greater understanding of the epidemiology of late blight. For genetic studies of this genus, however, it is important to select isolates with as high a potential to germinate as possible so that selected clonal isolates from single oospores will represent a normal population.

When leaves of differential varieties of potato were inoculated with clonal isolates from single oospores, pathogenic races different from the parental isolates were identified, suggesting that genetic recombination occurred. From the cross 445 (race 0)  $\times$  473 (race 1, 2, 3, 4) race 1,

race 2, race 3, race 4, race 1, 3, race 1, 4, race 1, 3, 4, and race 2, 3, 4 were identified by their ability to infect varieties of potatoes with corresponding single dominant genes. Thus new races may arise through the sexual stage of the fungus in Mexico, the only country in the world where two sexual compatibility types are known<sup>1,2,9,10</sup>. In compatibility tests twenty-three cultures from single oospores were A1 and only six were A2, indicating that the inheritance of compatibility factors depends on a more complex mechanism than that of a single pair of alleles. In addition to variation in pathogenicity and compatibility, variation in rate of mycelial growth, type and colour of mycelium, and amount of sporulation was also manifested by clonal cultures on CV-8A.

No segregation among progeny from any single oospore was noted. This suggests that only one genotype is present in each single oospore culture and agrees with the findings of Galindo<sup>11,12</sup> and Satour<sup>8</sup>.

Oospores, apparently parthenogenic, were produced in an unpaired culture by the isolate 445. Progeny from germ-mycelia derived from four of these oospores showed the same pathogenic character and compatibility type as the parental isolate 445 (race 0, A2) suggesting that parthenogenic oospores may not be a source of variation.

This study confirms previous reports<sup>2,6,10</sup> that genetic recombination does occur in the sexual cycle of *P. infestans* and that this process is an important factor influencing the appearance of new pathogenic races of the fungus.

## PHYSIOLOGY

### Electroretinographic "Threshold" in the Isolated Rabbit Retina

BASED on Sickel's technique<sup>1</sup> in the isolated frog retina a perfusion method has been developed during the last few years to keep the isolated warm blooded retina alive. By this method the negative *a*-wave and positive *b*-wave of the electroretinogram can be preserved<sup>2-4</sup>, and the isolated retina of the rabbit can be used to study physical and chemical effects. The preparation has always been assumed to retain normal light sensitivity, and we have tested this assumption.

The retinas of twelve rabbits were prepared in deep red light, freed of pigment epithelium and perfused by a technique described before<sup>2</sup>. The retinas were then tested with standard light flashes (0.05 lm/m<sup>2</sup> intensity and 0.1 sec duration). Two of the twenty-one retinas prepared produced an electroretinogram amplitude of less than 150  $\mu$ V and were discarded. In the remaining nineteen retinas the standard amplitude of the electroretinogram was between 150 and 650  $\mu$ V ( $372 \pm 130$   $\mu$ V).

After recording the electroretinographic response to a single standard flash, the responses to repeated weak stimuli were added by computer (CAT 1000; 120 responses to each intensity; stimulus duration 0.3 sec; stimulus interval 6 sec; white light of 3,200 °K). A suprathreshold reaction was assumed if the average amplitude of a response was more than 1  $\mu$ V. The threshold was lower than  $5 \times 10^{-5}$  lm/m<sup>2</sup> in all retinas. In fifteen retinas the threshold was lower than  $3 \times 10^{-5}$  lm/m<sup>2</sup>, and in twelve retinas it was lower than  $1 \times 10^{-5}$  lm/m<sup>2</sup>. No response was obtained with a stimulus intensity of less than  $1 \times 10^{-6}$  lm/m<sup>2</sup> (Fig. 1).

The tests were repeated after light adaptation of the retina (5 min, 50 lm/m<sup>2</sup>). In these conditions the electroretinogram was strongly reduced showing that the positive response was not an artefact (Fig. 1).

The isolated retina therefore seems to be fairly sensitive to light. Direct comparison with the electroretinogram of the intact animal is difficult because the signal to noise ratio is much lower without isolation. A luminance of 1 cd/m<sup>2</sup> in the stimulus field produces a retinal illumination of approximately  $0.24 \pm 0.08$  lm/m<sup>2</sup> ( $n=6$ ) in the dilated rabbit's eye (for a pupil of diameter 10 mm). In a sensitive isolated preparation  $4 \times 10^{-6}$  lm/m<sup>2</sup> is sufficient to elicit an electroretinogram (Fig. 1); this retinal illumination would correspond to a luminance of  $17 \times 10^{-6}$  cd/m<sup>2</sup>. The brightness threshold of the rabbit is unknown; it may be mentioned, however, that the brightness threshold in man was found to be  $0.85 \times 10^{-6}$  cd/m<sup>2</sup> (ref. 5). Our results with the rabbit are slightly more than 1 log unit higher. The electroretinogram "threshold" of the isolated frog retina was measured with monochromatic light (507 m $\mu$ ): with  $5.68 \times 10^{-14}$  W/cm<sup>2</sup> it was found to be slightly more than 1 log unit higher than the human brightness threshold<sup>6</sup>.

The relationship between the amplitudes of stimulus and the electroretinogram response has been found to be very similar in the isolated retina of the rabbit and in the intact animal<sup>7</sup>. The low electroretinogram "threshold" described in the present study also supports the assumption that the light sensitivity of the isolated preparation is nearly normal.

Fig. 1. Electroretinograms evoked from the isolated perfused rabbit retina with flashes of light (0.1 or 0.3 sec). Single responses ( $N=1$ ) and summated responses ( $N=120$ ). Intensity of retinal illumination is given in lm/m<sup>2</sup> (= lux). LA: Light adaptation (after 5 min illumination with 50 lm/m<sup>2</sup>). Negativity downwards. The electroretinogram threshold is somewhere between the first and the second record in the left row. In the summated responses a small negative stimulus artefact can be seen.

## Electrical Potential across the Rat Small Intestine stimulated by Adenosine Triphosphate

TRANSPORT processes in the small intestine are dependent on energy which suggests the participation, directly or indirectly, of adenosine triphosphate (ATP). No evidence has, however, been produced that exogenous ATP can influence intestinal transport processes, which may well result from the difficulty of getting the unstable ATP molecule to the correct place in the cellular organization before its hydrolysis occurs. A way around this difficulty is offered by the study of electrical potentials in the intestine, which are known to be associated with intestinal transfer of various substances. Potential changes can be measured within a few minutes of setting up the intestinal preparation, and appear within seconds after addition of transferable substances. They therefore appear to offer an ideal method for studying the effect of ATP on intestinal transfer.

The electrical potential was recorded across the wall of rat intestine<sup>1</sup>. Experiments were carried out in pairs, using two adjacent 6 cm sacs from the everted mid-jejunum, bathed in 30 ml. of bicarbonate saline<sup>2</sup>. In this preparation substances can be added to the mucosal fluid in which the sac is suspended, and this can easily be changed for a fresh solution. Sacs were incubated for 15 min before ATP was added, and the following results were obtained.

Addition of 1 mmolar ATP to the mucosal fluid caused a rise in potential after 15 sec, which reached a peak in 60–70 sec and fell to the original level after about 6 min. The mean potential increase was 2.85 ( $\pm 0.20$ ) mV, the serosal side being positive. This change is considerably larger than that obtained from addition of transportable hexoses or amino-acids at the same concentration. A concentration of 0.1 mmolar caused a potential of about 1.6 mV and even 0.01 mmolar produced a potential of 0.6 mV; hexose and amino-acid at a concentration of 0.01 mmolar had no detectable effect on the potential. After the initial response to 1 mmolar ATP subsequent addition of ATP produced a much smaller response.

Addition of AMP or ADP (1 mmolar) produced much smaller effects, which suggests that ATP is specific and probably supplies energy for an ionic transport process. (A slight contamination of the AMP and ADP with ATP could be responsible for these changes.)

We also studied a number of inhibitors, with the following results. Phlorrhizin ( $2 \times 10^{-4}$  molar) had no effect on the ability of ATP to stimulate the potential. This is of interest in relation to the conclusion<sup>3</sup> that although phlorrhizin inhibits the stimulation of fluid transport by mucosal glucose it does not affect the coupling of hexose metabolism to fluid transport.

Addition of 2:4-dinitrophenol ( $2 \times 10^{-4}$  molar) prevented the development of a potential by ATP. The

transfer potential caused by galactose was found to be inhibited by 2:4-dinitrophenol<sup>1</sup> and the present observation raises the question whether DNP uncouples the action of ATP in generating the potential, as distinct from uncoupling the generation of ATP by oxidative phosphorylation.

Ouabain ( $10^{-3}$  molar) in the serosal fluid caused approximately 50 per cent inhibition of the potential generated by ATP but had no effect when present in the mucosal fluid. This is of interest in connexion with the well known inhibitory effect of ouabain on the sodium pump, which depends on membrane ATPase activity.

The effect of ionic environment was studied by replacing the sodium chloride in the bathing fluids by mannitol, choline chloride or potassium chloride, thereby reducing the concentration of sodium to 25 mequiv./l. Sacs were pre-incubated 20 min before the addition of 1 mmolar ATP.

Replacement with potassium chloride prevented the potential which is stimulated by ATP, but replacement with mannitol or choline chloride increased the ATP potential to about 6 mV. This is of interest in relation to the finding that replacement of sodium chloride with potassium chloride abolished the hexose transfer potential but replacement with mannitol did not<sup>4</sup>. We are unable at the moment to offer an explanation for the stimulation of the ATP potential in the presence of mannitol or choline chloride, but it may be related to alteration in the ratios of sodium to potassium in the system.

In the presence of galactose, ATP caused an increase in potential identical to that in the absence of galactose—that is, 2 mmolar galactose gives a potential of 2 mV, whereas 2 mmolar galactose together with 1 mmolar ATP gives 5 mV. In the presence of glucose (2 mmolar), however, a smaller increase (1.5 mV) is observed when ATP is added.

These results show that ATP in low concentrations stimulates the potential across the rat small intestine, and are in keeping with the action of ATP on a sodium pump. The experiments seem to provide the first demonstration that utilization of ATP plays a direct part in the intestinal transfer process.

## Effect of Lithium on the Uptake of Noradrenaline by Synaptosomes

THERE is indirect evidence of a relationship between serious disorders of mood, such as mania and depression, and amines, particularly noradrenaline<sup>1,2</sup>. This is based in part on the observation that two classes of drugs which deplete the brain of noradrenaline (reserpine and alpha-methyl-DOPA), acting through different mechanisms, can cause depression in some patients. The imipramine class of drugs and the monoamine oxidase inhibitors have been shown in controlled studies to benefit many clinical depressions. The monoamine oxidase inhibitors have been found to block an important breakdown pathway of

noradrenaline<sup>1</sup>, while the imipramine type drugs block the re-uptake of noradrenaline into the adrenergic tissues<sup>1</sup>. It has been suggested that both classes of drugs increase "functional" noradrenaline at the receptor sites, and that this effect is related to their antidepressant actions.

Well controlled studies indicate that lithium is a highly effective treatment for mania<sup>3,4</sup>. There is evidence that lithium maintenance treatment can prevent the recurrence of manic or depressive episodes in patients with a history of recurrent mania, depression or both<sup>5,6</sup>. Depression may be associated with altered metabolism of noradrenaline and function, and depression and mania are clinically related, and so it seemed reasonable to investigate whether chronic lithium administration would modify the function of noradrenaline. The hypothesis tested is whether or not lithium pretreatment would affect the uptake of noradrenaline by isolated nerve endings.

A group of eighteen Sprague-Dawley rats were given 2 mequiv of lithium carbonate in their food each day, while 11 untreated animals were maintained as controls in similar conditions. This dosage was sufficient to maintain serum lithium levels between 1 and 2 mequiv./l. The treatment period varied between 5 and 7 days because a similar time is required for improvement to occur with the clinical use of lithium in mania.

The nerve endings "synaptosomes" were prepared by the subcellular fractionation technique of Whittaker<sup>7</sup>. The animals were decapitated and the brains were quickly removed, chilled, weighed, and then ground in nine volumes of 0.32 molar sucrose in a special homogenizer. The homogenate was centrifuged at 900*g* for 15 min to remove the nuclei as a pellet, and the supernatant was centrifuged at 17,000*g* for 30 min, leaving the microsomes in the supernatant and the myelin, synaptosomes, and mitochondria in the pellet. The pellet fraction was resuspended in 8 ml. of 0.32 molar sucrose, layered on a discontinuous sucrose gradient with 8 ml. layers of 1.2 molar and 0.8 molar sucrose and centrifuged at 50,000*g* for 90 min. The synaptosomal fraction (middle) was then recovered with a special tube-slicing device (Beckman Instruments) and diluted to 52 ml. with Krebs bicarbonate buffer<sup>8</sup>.

Tritiated noradrenaline, 0.2  $\mu$ c. (*dl*-noradrenaline-7-<sup>3</sup>H acetate, New England Nuclear Corp.) was added without carrier to the buffered nerve ending fraction, resulting in a final concentration of noradrenaline in the incubation medium of 1.2  $\mu$ g/ml. The synaptosomal fraction from each animal was divided into eight parts (6 ml. each), providing samples which were usually run in duplicate for four periods of incubation (0, 4, 8, 12 min) at 37° C. All samples were then centrifuged at 100,000*g* for 10 min, washed with 8 ml. of buffer and recentrifuged. The resulting pellets were extracted with 0.25 ml. of 0.4 normal perchloric acid and centrifuged at 50,000*g* for 10 min, 0.2 ml. of aliquot being transferred to a scintillation mixture for counting. (The mixture consisted of: 10 ml. toluene; 4 ml. of ethanol containing 0.4 per cent 2,5-diphenyloxyazole; and 0.01 per cent 1,4-bis-2-(phenol-oxazyl)-benzene.)

The quenching for each sample was observed with an external Beta monitor in a Model 4000 Packard scintillation spectrometer. The addition of the perchloric acid extract from our samples gave essentially the same quenching as perchloric acid alone—about 20 per cent. The range of quenching between the individual samples was only 3–4 per cent. Paper chromatography of the perchloric acid extracts in a butanol:acetic acid:water system (25:4:10) revealed that 90 per cent of the radioactivity travelled with an authentic noradrenaline carrier, indicating that most of the radioactivity was due to noradrenaline rather than breakdown products of noradrenaline. Concentrations of lithium in blood and tissue were determined by atomic absorption (Perkin-Elmer Model 303), with lithium carbonate as the reference compound.

Fig. 1 shows the uptake of noradrenaline by the synaptosome fraction after incubation at 37° C for 0, 4, 8

Table 1. NET UPTAKE OF NORADRENALINE BY SYNAPTOSOMES WITH AND WITHOUT LITHIUM PRETREATMENT

Incubation period* (min)	Net uptake and method error (c.p.m.)				Net uptake minus zero uptake/time period		Uptake increase with lithium pretreatment (per cent)
	Control Net uptake	Method error† (per cent)	Lithium pretreatment Net uptake	Method error† (per cent)	Control	Lithium	
0	2,144	10.5	2,600	4.2	—	—	—
4	7,357	6.4	9,431	5.6	5,213	6,831	31
8	13,993	4.8	17,978	6.7	11,849	15,378	30
12	20,326	2.8	25,219	5.1	18,182	22,619	24

\* The differences between time periods 0–4, 4–8, and 8–12 min were significant at the 0.0001 level for both lithium and controls.

† The percentage method error was calculated by dividing the mean difference between duplicate measurements by the net uptake for a given time period. For the twenty earlier experiments samples were run in duplicate. The latter nine experiments were not run in duplicate for the method variance was considerably smaller than the variance between animals.

and 12 min. Chronic lithium pretreatment increases the net uptake by approximately 30 per cent at 8 and 12 min (see Table 1). This increase in net uptake in the lithium pretreated rats is significant at the 4 (0.02), 8 (0.001) and 12 (0.001) min periods (*t*-test based on mean of duplicate determinations). On each experimental day control rats were compared with one or two rats pretreated with lithium, and so a comparison between lithium and control can be made for each day. In every case the mean lithium value for that day showed greater uptake than the control value, a finding itself significant at the 0.002 level for each period (Wilcoxon signed-ranks test).

The concentration of noradrenaline in the incubating medium was about 6,200 c.p.m./0.1 ml., whereas the concentration in the synaptosomal fraction after 12 min incubation was approximately 60,000 c.p.m./0.1 ml. This ten-fold increase in concentration of the synaptosomal fraction over the medium would argue against simple diffusion as the sole explanation for the results. When small amounts of lithium, ranging from 0.5 to 5 mequiv./l., were added to the incubation medium, no increase in uptake by the synaptosomes was observed in the control animals or the animals treated with lithium. Lithium levels in the serum were 1 to 2 mequiv./l., and in the whole brain were 0.5 mequiv./kg. Lithium concentrations in the synaptosomes and microsomes were 16 per cent and 10 per

Fig. 1. Uptake of noradrenaline by synaptosomes isolated from lithium and control animals.  $\Delta$ — $\Delta$ , Treated;  $\bullet$ — $\bullet$ , control; S.E.M., standard error of the mean for all the lithium and control samples at the four time periods. The numbers of animals used in determination of each point for 0, 4, 8, and 12 min were eighteen, seventeen, eighteen, seventeen and eleven, eleven, ten, nine, respectively, for treated and untreated animals.

cent of the whole tissue levels, whereas only 5.8 per cent and 2.5 per cent, respectively, were found in the myelin and mitochondria.

Synaptosomes isolated from the brains of rats pretreated with lithium have been shown to take up noradrenaline against a concentration gradient to a significantly greater extent than control animals. That this effect may be due to the lithium directly is consistent with the findings of relatively high concentrations of lithium in the synaptosomes. The mechanism by which lithium increases net "uptake" in this system, however, is not yet clear. It may alter the membrane directly, interact with an enzyme and/or transport mechanism, deplete endogenous norepinephrine levels, affect adrenergic binding sites or interact with cations as they affect amine uptake<sup>9-13</sup>.

The use of the synaptosomal fraction has the advantage of providing a system consisting primarily of nerve endings, and hence reduces the possibility that non-specific diffusion, binding or uptake by other subcellular particles could obscure or confound small but real differences in synaptosomal uptake. In an *in vivo* experiment, Schanberg, Schildkraut and Kopin<sup>14</sup> found that acute lithium pretreatment altered the metabolism of tritiated noradrenaline in rat brain, increasing the ratio of deaminated to *o*-methylated metabolites. Our data suggest that these results could be explained if lithium pretreatment increased re-uptake of noradrenaline *in vivo*.

We have seen that the relative rates of release and re-uptake of noradrenaline at the central adrenergic nerve ending may be related to alterations in mood states<sup>1,15</sup>. The data reported here suggest a hypothesis for further study: that the therapeutic efficacy of lithium in mania may in part be a result of an increased re-uptake of noradrenaline, with a resultant decrease in the noradrenaline available for interaction with the receptor sites.

Electrolytes as well as noradrenaline have been implicated in mood disorders<sup>16-18</sup>. Furthermore, clinical evidence<sup>19</sup> suggests that mania and depression are not in all respects opposite, nor may biogenic amines and electrolytes be involved in any simple way. The experiments reported here describe an *in vitro* system for precise study of the inter-relationships between electrolytes and amine function—inter-relationships which may be important to the understanding of affective disease.

## Technetium-99m(V)-Citrate Complex for Estimation of Glomerular Filtration Rate

THE standard compound used for estimating the rate of glomerular filtration is inulin, but its chemical determination is tedious and time consuming. The technique for estimating the filtration rate with inulin requires constant infusion and serial urine collections. <sup>14</sup>C-carboxyl-, <sup>131</sup>I- and <sup>125</sup>I-allyl-inulin have been suggested, but chemical instability, cost and lack of rapid and simple methods of analysis have limited their use<sup>1-3</sup>. A compound labelled with a gamma emitting isotope and excreted entirely by glomerular filtration would make the study of renal function much easier, and <sup>131</sup>I- (also <sup>125</sup>I-) diatrizoate<sup>4,5</sup>, <sup>131</sup>I- (also <sup>125</sup>I-) iothalamate<sup>6</sup>, <sup>57</sup>Co-vitamin B<sub>12</sub> (refs. 7-9), and <sup>51</sup>Cr-ethylenediamine tetraacetate<sup>10</sup> have received attention. There are, however, disadvantages in using these labelled compounds for estimating the rate of glomerular filtration when successive examinations are attempted in the presence of poor or rapidly declining renal function. In these conditions, the radioactivity of plasma tends to increase to levels great enough to reduce the accuracy of the measurements, because of the relatively long half life of these nuclides. <sup>57</sup>Co-vitamin B<sub>12</sub> has two further disadvantages: it is appreciably bound to plasma protein<sup>11</sup>, and it has a long residence time in the liver so that its repeated use in a patient with seriously impaired renal function would be undesirable.

Yeh and Kriss<sup>12,13</sup> described physiological investigations with a new and easily synthesized compound, technetium-99m(V)-citrate complex. Distribution and scintiphographic studies indicated that the drug was rapidly excreted by the kidney as the intact complex. The physiological behaviour of the complex plus the favourable physical characteristics of technetium-99m (ref. 14), that is, its short physical half-life (6 h) and low gamma energy (140 KeV), encouraged us to study the mechanism of its renal excretion by both the single injection<sup>15</sup> and standard clearance techniques.

The renal clearances of <sup>131</sup>I-diatrizoate (specific activity about 200  $\mu$ c. <sup>131</sup>I/mg; each dog received 2  $\mu$ c. of <sup>131</sup>I/kg of body weight) and technetium-99m(V)-citrate complex were compared simultaneously in ten conscious dogs with weights of between 17 and 24 kg. (Technetium-99m(V)-citrate complex was prepared by the method of Yeh and Kriss<sup>12,13</sup>. To obtain better reduction of <sup>99</sup>Tc from +7 to +5 oxidation state, 1.5 normal hydrochloric acid was used. Subsequently the citrate concentration increased to 0.25 molar. The final product had specific activity 125-250  $\mu$ c./ml. depending on the age of the <sup>99m</sup>Tc generator, and consisted of citric acid of approximately 40 mg/ml. The purity of the material was examined by ascending paper radiochromatography. The free <sup>99m</sup>Tc-pertechnetate was less than 2 per cent. Each dog received 200-400  $\mu$ c. The compound did not bind to red blood cells. The animals had no acute toxic reactions and were observed for several weeks and none showed any late toxic effects.) After a single intravenous injection of a mixture of <sup>131</sup>I-diatrizoate and technetium-99m(V)-citrate complex, heparinized samples of venous blood were collected at 5-10 min intervals for 90-140 min. The counts of each isotope contained in 1 ml. of plasma were determined in a well-type scintillation counter, using appropriate gamma-ray energy discriminator settings. A sample of the injected dose was diluted and 1 ml. was analysed in the same manner. The clearances, distribution volumes and intercompartmental clearances were calculated by a computer, using the formulae derived by Sapirstein *et al.*<sup>16</sup> as applied to the plasma <sup>131</sup>I-diatrizoate disappearance curve by Blafox *et al.*<sup>17</sup>. They showed no statistical difference in glomerular filtration rates when simultaneously determined in dogs by the techniques of a single injection of <sup>131</sup>I-diatrizoate and the constant infusion of

Fig. 1. Plot of typical plasma disappearance rates of  $^{131}\text{I}$  (a) and  $^{99\text{m}}\text{Tc}$  (b) after a single intravenous injection of a mixture of  $^{131}\text{I}$ -diatrizoate and technetium-99m(V)-citrate complex. The curves are resolved by eye-fit into their two slopes,  $\lambda_1$  and  $\lambda_2$ , which results in their respective intercepts  $B$  and  $A$ .

creatinine. The computer was programmed to perform calculations based on the following equations

$$C = \frac{D \cdot \lambda_1 \cdot \lambda_2}{A \cdot \lambda_1 + B \cdot \lambda_2} \quad (1)$$

$$V_1 = \frac{D}{A + B} \quad (2)$$

$$\alpha = \frac{V_1(A \cdot \lambda_2 + B \cdot \lambda_1)}{A + B} - C \quad (3)$$

$$V_2 = \frac{\alpha \cdot C}{V_1 \cdot \lambda_1 \cdot \lambda_2} \quad (4)$$

where  $C$  is renal clearance;  $D$  is dose;  $A$  and  $B$  are the intercepts of the fast and slow components of the plasma disappearance curve;  $\lambda_2$  and  $\lambda_1$  are the slopes of the fast and slow components;  $V_1$  is the volume of compartment 1 into which doses were injected;  $\alpha$  is intercompartmental clearance; and  $V_2$  is the volume of compartment 2 which is made up of the rest of the apparent distribution volume. The terminal slope was taken from the plasma radioactivity between 40 and 80 min. The second slope was determined from the difference in a line drawn between the 40–80 min points and the plasma radioactivity between 5 and 25 min.

The renal clearances were also determined by plotting the plasma radioactivity against time on semilogarithmic paper and resolving the disappearance curve by eye-fit. Fig. 1 shows typical plasma disappearance curves from a single intravenous injection of a mixture of  $^{131}\text{I}$ -diatrizoate and technetium-99m(V)-citrate complex. The slopes of the curves are identical. The ratio of the renal clearance of  $^{131}\text{I}$ -diatrizoate : renal clearance of technetium-99m(V)-citrate complex for the ten dogs averaged  $1.003 \pm 0.002$  standard error (Fig. 2a). The coefficient of correlation between the clearance rates of the two compounds with this technique was 0.99. The calculated distribution volumes and intercompartmental clearances of the two compounds were also nearly identical (Table 1).

The renal clearances were also determined in a well hydrated dog under anaesthesia. The urine was collected by bladder catheter during ten 15 min periods. A priming dose of a mixture of  $^{131}\text{I}$ -diatrizoate and technetium-99m(V)-citrate complex was injected intravenously, followed by constant infusion of the mixture. A venous

blood sample was taken at the mid-point of each collection period. The radioactivity in 1 ml. of plasma and urine was determined. The renal clearance rates were calculated by the standard formula  $UV/P$ . In these conditions, the clearance rates of the two substances were identical (Fig. 2b).

The plasma disappearances of  $^{131}\text{I}$  and  $^{99\text{m}}\text{Tc}$  following a single intravenous injection of a mixture of  $^{131}\text{I}$ -diatrizoate and technetium-99m(V)-citrate complex were determined in one dog immediately after bilateral nephrectomy had been performed. The plasma disappearance curve of  $^{99\text{m}}\text{Tc}$  is shown in Fig. 3. The  $^{131}\text{I}$  plasma disappearance curve was quite similar. The slight decline observed after the initial mixing phase was most likely caused by excretion into the bile. Aspiration of the gall bladder 60–70 min after the injection revealed small amounts of both  $^{131}\text{I}$  and  $^{99\text{m}}\text{Tc}$  in the bile. The biliary concentration of the two nuclides as compared with their respective concentrations in the injection

mixture represented identical degrees of dilution. Inulin is also excreted in small quantities into the bile<sup>18</sup>. These observations suggest metabolic inertness and absence of other mechanisms of excretion.

Table 1. COMPARISON OF DISTRIBUTION VOLUMES AND INTERCOMPARTMENTAL CLEARANCES OF TECHNETIUM-99m(V)-CITRATE COMPLEX AND  $^{131}\text{I}$ -DIATRIZOATE

Dog No.	Weight (kg)	Technetium-99m(V)-citrate complex			$^{131}\text{I}$ -diatrizoate		
		$V_1$ (l.)	$V_2$ (l.)	inter-comp. clearance (ml./min)	$V_1$ (l.)	$V_2$ (l.)	inter-comp. clearance (ml./min)
1	16.8	2.75	40	0.80	2.68	43	0.88
2	20.5	3.40	112	1.91	3.36	108	1.94
3	21.8	3.99	69	1.77	4.03	74	1.68
4	21.4	2.49	84	1.60	2.44	90	1.62
5	31.4	3.45	111	1.82	3.55	118	1.69
6	16.8	2.66	37	1.08	2.81	46	0.92
7	21.4	2.93	99	1.78	3.04	92	1.71
8	18.2	3.83	112	2.27	3.78	121	2.34
9	24.5	4.50	153	2.25	4.37	146	2.07
10	24.1	3.54	189	2.73	3.68	164	2.59
Mean	21.7	3.36	101	1.80	3.37	100	1.74

$V_1$ , Volume of compartment 1 into which doses were injected;  $V_2$ , volume of compartment 2 which is made up of the rest of the apparent distribution volume.

The average calculated technetium-99m(V)-citrate complex and  $^{131}\text{I}$ -diatrizoate space in the ten dogs were 23.8 per cent and 23.5 per cent of body weight, respectively. These values are not significantly different from the inulin space of dogs reported by Gaudino *et al.*<sup>19</sup>. We consider it unlikely that the identical values for renal clearance of the two labelled compounds could have resulted from a fortuitous combination of filtration plus

Fig. 2. Correlations between the calculated renal clearances by the single injection technique in ten dogs (a), and the measured renal clearances by the constant infusion technique for ten clearance periods in one dog (b) of  $^{131}\text{I}$ -diatrizoate and technetium-99m(V)-citrate complex.

Fig. 3. Plot of plasma-disappearance rate of  $^{99m}\text{Tc}$  after injection of a mixture of  $^{131}\text{I}$ -diatrizoate and technetium- $^{99m}\text{(V)}$ -citrate complex in a dog immediately after bilateral nephrectomy. It is noted that the slopes  $\lambda_1$  and  $\lambda_2$  have common intercepts. The curve is corrected for decay during counting.

identical rates of tubular secretion and re-absorption of technetium- $^{99m}\text{(V)}$ -citrate complex.

Advances in the diagnosis and treatment of renal diseases and the need for a more precise tool to monitor the immunological reaction in clinical renal allotransplantation have stimulated interest in gamma emitting isotopes for the serial and simultaneous determinations of glomerular filtration rate and effective renal plasma flow<sup>20-22</sup>. It would be especially valuable to have techniques which would eliminate the need for collections of urine. The combination of  $^{131}\text{I}$ - (or  $^{125}\text{I}$ -) diatrizoate and  $^{125}\text{I}$ - (or  $^{131}\text{I}$ -) hippuran has been applied<sup>23,24</sup>, but the long half lives of these nuclides allow accumulation of plasma radioactivity in the presence of poor or rapidly declining renal function. Because of the short half life of  $^{99m}\text{Tc}$  and the physiological behaviour of the easily prepared technetium- $^{99m}\text{(V)}$ -citrate complex, the agent is well suited for repeatedly determining glomerular filtration rate by the single injection technique, especially when renal function is poor.

Our results suggest that technetium- $^{99m}\text{(V)}$ -citrate complex, like  $^{131}\text{I}$ -diatrizoate, fulfils the requirement necessary for a compound used for estimating glomerular filtration rate and should be valuable in the investigation of renal function.

We thank Dr Eugene Dong for assistance in setting up the computer programme and Mr Cornelis Ploeg and Mr Stephen Freese for technical assistance. This work was supported by grants from the US Public Health Service and the Milheim Foundation for Cancer Research. We thank Nuclear Consultants, Inc., for the gift of technetium- $^{99m}$ .

### Change in the Concentration of Lactic Acid in the Rat and Hamster Brain during Natural Sleep

Richter and Dawson<sup>1</sup> first reported that young rats killed by immersion in liquid nitrogen during natural sleep showed a decrease in the concentration of lactic acid in the brain when compared with control animals in the normal waking state, but experimental confirmation of this finding has not been published. Shimizu *et al.*<sup>2</sup> have recorded a failure to confirm it in experiments involving brief periods of sleep.

I have now reinvestigated the lactic acid content of the brain in small rodents under various physiological conditions and have confirmed the original observation that there is a significant decrease in the concentration of lactic acid in the brain during natural sleep.

Adult male Syrian hamsters and MRC  $T_1$  male albino rats between the ages of 10 and 60 days were used. The rats and hamsters were left undisturbed to sleep naturally for a period of at least 30 min before they were killed. The animals slept in a conical polythene container from which they were tipped after the required time into liquid nitrogen. When completely frozen, the heads were broken from the carcasses and kept in liquid nitrogen. The brains were chiselled free and homogenized at  $-10^\circ\text{C}$  in 6 ml. of 1 normal perchloric acid. The homogenate was kept at  $-25^\circ\text{C}$  overnight. On thawing, the homogenate was centrifuged at  $3,000g$  for 10 min in a bench centrifuge and the supernatant decanted. The residue was washed with 2 ml. of normal perchloric acid, centrifuged as before and the supernatant combined with the first. The acid extract was neutralized at  $4^\circ\text{C}$  with 12.5 normal potassium hydroxide. The solution was frozen and then allowed to thaw at  $4^\circ\text{C}$  to attain maximum precipitation of potassium perchlorate. When complete, the potassium perchlorate crystals were separated by centrifugation, washed with ice-cold water and discarded. The water wash was combined with the original extract and the whole made to 10 ml. Volumes of 200 and 400  $\mu\text{l}$ . were taken for the assay of lactic acid, which was measured enzymatically by a method based on that described by Bergmeyer<sup>3</sup>. The incubation mixture was 1 molar glycine buffer, pH 9.5, containing 2 mmolar DPN, 0.4 molar hydrazine sulphate and 5 mmolar EDTA.

Table 1. BRAIN LACTIC ACID CONCENTRATION DURING SLEEP

Animal	Control	Sleep	P
Rat, young (50 g)	1.46 ± 0.103 (24)	1.23 ± 0.108 (18)	0.05
adult (150 g)	3.14 ± 0.141 (30)	2.25 ± 0.173 (25)	0.0005
Hamster, adult (100 g)	3.11 ± 0.130 (35)	1.97 ± 0.086 (26)	0.0005

Results expressed as  $\mu\text{moles/g}$  of lactic acid  $\pm$  standard error of the mean. The number of animals is in parentheses.

In preliminary experiments it was found that the concentration of lactic acid in the rat brain changes with age from about 0.9  $\mu\text{moles/g}$  at 1 day old to the adult level of 3.14  $\mu\text{moles/g}$  at 35–40 days old. Some difficulty was experienced at first in inducing natural sleep in rats, because the experiments were carried out with adult rats weighing 150 g and I found that adult rats are very easily aroused. A difference between sleeping and waking animals was obtained with young rats of 50 g body weight, and this could also be shown in adult rats providing the rats were left to sleep undisturbed for at least 30 min. The same change could be shown in adult hamsters. Table 1 gives the results from such experiments. In the young rat the content of lactic acid in the brain decreased by 15 per cent during sleep, while in the adult it decreased by 28 per cent. The adult hamster showed a decrease of 36 per cent.

### "Afterpotential" in the Cochlear Response

THE existence of a maintained summing potential (SP) seen in the avian<sup>1</sup> and mammalian<sup>2</sup> cochleas during strong tonal stimulation is a well established phenomenon and can be explained in terms of non-linear movements of the cochlear transducer mechanism<sup>3</sup>. Transients are seen at the onset and termination of such stimuli and can be studied with the aid of averaging techniques<sup>4</sup>. These transients are also asymmetric, their mean values being represented as deflexions of the SP which are of the same polarity (negative-going) both at the onset and cessation of the tone burst. This is, of course, the result to be expected if the asymmetry of the transducer mechanism were such as to produce a negative SP.

This response is, however, seen only at rather short durations of stimulation (20–50 msec) (Fig. 1). If the length of the tone burst is increased to, say, 500 msec, the off-transient is obscured by a positive-going "slow-wave", the amplitude and duration of which are dependent on the duration of the preceding stimulus. The slowwave is unaffected by section of the middle ear muscles and presumably cannot therefore arise from a reflex of the middle ear. Both the negative transients and the positive slowwave are seen equally well in the cat,

Fig. 1. The summing and transient potentials recorded from the pigeon cochlea in response to 1,600 c/s tone bursts of (A) 20 msec and (B) 400 msec duration. Mammalian responses are similar. Upward deflexion represents relative positivity in the scala tympani ("negative summing potential"). Averages of 160 sweeps with dwell times of 5 and 10 msec/point, respectively. Calibration, 10  $\mu\text{V}$ .

guinea-pig and pigeon and whether recorded from the scala tympani or from the intact round window.

The negative-going transients are influenced by the times of rise and fall of the stimulus and are most marked when the stimulus rises abruptly to its full value in one half cycle of the stimulus. They are almost completely abolished when the rise time is of the order of 50 msec, although the precise values are dependent on other factors, such as intensity and frequency of stimulus. They thus have the properties of true system transients.

By contrast, the positive slowwave seems to be entirely uninfluenced by the rate of turn-off, and is affected solely by the amplitude and duration of the previous stimulus. I have been unable to devise any explanation of this potential in terms of the mechanics of the basilar membrane, and the only possible explanation seems to be that it is associated in some way with the hair cell generator mechanism. Stimulation of the olivo-cochlear bundle, although it influences the size of the whole electric response, does not selectively influence the positive slowwave, and it seems unlikely that the latter could be due to a delayed efferent volley. In any case, the recent observations by Fex<sup>5</sup> show that potentials produced by olivo-cochlear activity are of the opposite polarity to the response which we are observing. The similarity of shape and behaviour between this potential and the afterpotential seen in neurones following repetitive firing suggests that this wave may be of similar origin and may represent an afterpotential of the hair cells themselves or of the hypothetical afferent transmitter mechanism.

### Possible Role of Alveolar Surfactants in the Uptake of Inhaled Gases

MOST inhaled anaesthetic gases and many other physiologically important gases are non-polar and have very poor solubility in highly polar water. At a temperature of 37° C there is a water vapour pressure in the alveolar area of 47 mm mercury, which implies the presence of a water layer on the alveolar membrane. The polarity of this water forms a barrier to the migration of non-polar anaesthetic and other non-polar gases through the alveolar membrane.

Simple partition and diffusion mechanisms cannot possibly account for the profuse amounts of non-polar gas which are transported through lung tissue to the blood stream. We suggest here that solubilization through the formation of micelles is responsible for the rapidity of absorption. Solubilization<sup>1</sup> has been defined as the spontaneous dissolving of a normally water-insoluble substance by an aqueous solution of surfactant. This solubilization effect becomes significant when the amount of individual surfactant molecules in solution exceeds a critical concentration and the molecules aggregate to form groups called micelles. This concentration of surfactant molecules is referred to as the critical micelle concentration (CMC). Each surfactant has its own characteristic CMC.

The presence of surfactant material in the alveolar matrix has been demonstrated many times<sup>2–4</sup>. Bondurant and Miller<sup>5</sup> found a phospholipid, predominantly phosphatidylcholine (lecithin), in lung surface active material

Fig. 1. Inability of homogenized lung without surfactant to solubilize halothane as compared with the marked ability of crude lung surfactant, and 'Tween 80' (a synthetic surfactant at concentrations of 3 and 30 per cent), to absorb the gas. Addition of 30 per cent 'Tween 80' to lung homogenate shows marked absorption as compared with lung homogenate alone, but less absorption as compared with 30 per cent 'Tween 80' alone. x---x, Lung homogenate; ○—○, crude surfactant extract; Δ...Δ, lung homogenate with 30 per cent 'Tween 80'; ●...●, 3 per cent 'Tween 80'.

and Brown<sup>6</sup> isolated dipalmitoyl lecithin as a lung surfactant. The characteristics of the micelles formed by the lecithin surfactants have recently been reviewed<sup>7</sup>, and their ability to solubilize material insoluble in water has been discussed<sup>8</sup>. DePalma *et al.*<sup>9</sup> have proposed that lecithin is a necessary component of these complexes.

In order to test our hypothesis, we prepared surfactant material, using the method of Bondurant and Miller<sup>5</sup>, by instilling normal saline into the lungs of dogs, ventilating them and extracting the foamy solution by suction. This procedure was repeated several times until no more foamy fluid could be obtained. The lung was then homogenized in saline in a Waring blender, centrifuged and the supernatant separated from the homogenate. The supernatant was then tested in the same way as the crude surfactant material and the lung homogenate.

The materials obtained were placed individually in a modified tonometer (150 ml. capacity) which had an extraction port fitted with a rubber septum for sampling gas. Halothane vapour, 1 per cent in oxygen, was admitted into the chamber, closed off and 0.1 ml. samples of the gas were extracted at intervals of 1 min for 20 min.

The samples were analysed by gas chromatography (katharometer) and quantified by comparison with freshly prepared standards.

The result of these tests is graphically summarized in Figs. 1 and 2. Lung homogenate (dog or human), prepared in saline to render it more fluid, showed virtually no absorption of halothane gas. Crude surfactant extract absorbed the gas very rapidly reducing the concentration of halothane in the tonometer by 40 per cent in 3–4 min. The absorption pattern observed when lung surfactant was added to homogenized lung did not differ significantly from that of lung surfactant alone. Lung homogenate did not improve the ability of surfactant to solubilize the gas.

A synthetic surface active agent, 'Tween 80', was tested for comparison at concentrations of 3, 30 and 70 per cent, at which increasingly larger aggregations (micelles) occur, as demonstrated by the sudden increase of halothane absorption (Table 1). 'Tween 80' at 3 per cent (Fig. 2) and at 30 per cent (Fig. 1) showed absorption characteristics that paralleled those of lung surfactant. Because 'Tween 80' at 70 per cent forms a gel, no attempt was made to mix it with lung homogenate.

When plotting surface tension against area in a film balance using crude extracts of lung surfactants, an area of hysteresis is obtained<sup>3</sup>. The hysteresis loop occurs on expansion and contraction of the film by the migration of surfactant molecules to the surface in sufficient concentration to form micelles and then, on the reverse cycle, the

Fig. 2. Minced human lung without surfactant (○—○) shows very poor absorption of halothane vapour. Crude surfactant extracted from it (x---x) and minced lung with crude surfactant (Δ...Δ) demonstrate excellent absorption of gas. Surfactant alone is better than surfactant added to the minced lung.

Table 1. UPTAKE OF HALOTHANE BY 'TWEEN 80' IN VARIOUS CONCENTRATIONS

\* At these concentrations there was a sudden marked ability to solubilize gas demonstrating "critical micelle concentration" (CMC).

return of the micelles into the solution where the surfactant molecules disperse.

We have suggested that a circulation of surfactant molecules takes place between the alveolar cell and the alveolar surface lining with changes caused by respiration. Thus with inspiration, increased pressure exerted on the alveolar cell increases the membrane surface and thereby forces more surfactant to migrate to the surface, instantly causing the formation of micelles which can readily solubilize non-polar gas or inhaled anaesthetics in the quantities observed. With release of pressure on exhalation, these micelles find their way back into the subphase and disaggregate, releasing the anaesthetic or molecular gases to be absorbed by the blood stream.

The marked ability of both crude lung surfactant and a 30 per cent concentration of 'Tween 80' to absorb or solubilize halothane in the presence or absence of underlying lung homogenate is highly indicative of solubilization by micelles. It is not inconceivable that some similar mechanism may play a part in the uptake of molecular gases by the red blood cell and plasma proteins.

## HAEMATOLOGY

### Second Kininase in Human Blood Plasma

COHN fraction IV-1 of human plasma contains an enzyme, carboxypeptidase N, which inactivates bradykinin and kallidin<sup>1,2</sup> and also cleaves smaller substrates such as hippuryl-L-lysine (HLL)<sup>3</sup>. The kininase also has an esterase activity—it hydrolyses the ester substrate hippuryl-L-argininic acid (HLAa)<sup>4</sup>. For the sake of simplicity in this communication, we shall refer to this enzyme as kininase I.

During purification of human carboxypeptidase N, we noticed the presence in plasma of a second bradykininase (kininase II) (refs. 3 and 4). This enzyme preparation inactivated bradykinin, although it did not hydrolyse HLL. This report describes the characterization and partial purification of kininase II.

The starting material for the experiments was obtained by means of gel filtration of fresh, heparinized human plasma on a 'Sephadex G-200' column. The peptidase and esterase activities, as measured with HLL and HLAa substrates, were found in a single protein peak (Fig. 1). The bradykininase gave a broader activity maximum, however, than the carboxypeptidase. When this plasma protein fraction containing the bradykininase activity was adsorbed on a DEAE-'Sephadex A-50' column and eluted stepwise, two bradykininases were separated (Fig. 2).

The peak that was eluted with 0.3 molar sodium chloride contained carboxypeptidase N, which hydrolysed HLL,

HLAa and bradykinin. This kininase I inactivated bradykinin by breaking the carboxyl terminal Phe<sup>8</sup>-Arg<sup>9</sup> bond of the peptide.

The peak which emerged during elution with 0.15 molar sodium chloride contained kininase II. It did not cleave HLL and hydrolysed HLAa only slightly but inactivated bradykinin when tested on the isolated rat uterus (Fig. 2).

The site of attack of kininase II in the bradykinin peptide was found by the combined use of thin-layer chromatography and the dansyl (1-dimethyl-amino-naphthalene-5-sulphonyl chloride) fluorescent labelling technique of Prado *et al.*<sup>5</sup>, by descending paper chromatography and by means of peptide mapping<sup>2</sup>. Thin-layer chromatography was performed on glass plates coated with silica gel G in an *n*-butanol : acetic acid : water (4 : 1 : 5 or 50 : 1 : 50) solvent. Paper chromatography was done on Whatman 3MM paper in the same solvent. Peptide mapping was used as previously described<sup>2</sup>. The split products of the reaction of kininase II with the substrates were separated by means of these techniques. These

Fig. 1. 'Sephadex G-200' filtration of human plasma kininases. 15 ml. of fresh heparinized human plasma was filtered through a 3.5 × 46 cm. column. A 0.05 molar phosphate buffer, pH 7, containing 0.5 moles/l. of sodium chloride was the eluent. 5 ml. fractions were collected every 30 min. HLL, Hippuryl-L-lysine; HLAa, hippuryl-L-argininic acid. —●—, Protein; —□—, hydrolysis of bradykinin; —▲—, hydrolysis of HLL; —○—, hydrolysis of HLAa.

Fig. 2. Separation of the two kininases on a DEAE-'Sephadex A-50' column. 300 mg of protein obtained after gel filtration was purified on a 1 × 30 cm. column. Fractions were eluted step by step by increasing the concentration of sodium chloride in a 0.02 molar phosphate buffer, pH 6.8. 5 ml. was collected every 30 min. The activity eluted with 0.3 molar sodium chloride contains kininase I (carboxypeptidase N). Kininase II moved with the fraction that was eluted with 0.15 molar sodium chloride. HLL, Hippuryl-L-lysine. —●—, Protein; —□—, hydrolysis of bradykinin; —▲—, hydrolysis of HLL.

substrates were bradykinin and Ac-Ser-Pro-Phe-Arg-OH. The latter compound represents the carboxyl terminal tetrapeptide sequence in bradykinin. It was acetylated to avoid hydrolysis by unspecific aminopeptidases at the amino terminal end<sup>6</sup>. In the experiments using paper chromatography 0.68–1.58 mg enzyme protein was incubated with 1  $\mu$ mole of substrate in a 0.07 molar *tris* buffer, pH 7.4, for 16 h at 31° C. In the thin-layer chromatography studies 0.13–0.32 mg of enzyme protein was used with 0.2  $\mu$ mole of substrate.

Kininase II cleaved the Pro<sup>7</sup>-Phe<sup>8</sup> bond in bradykinin and in the smaller substrate; it thus removed a Phe-Arg dipeptide from the carboxyl terminal end. The identity of Phe-Arg, one of the split products, was established by comparing its  $R_F$  value with synthetic Phe-Arg, by eluting the reaction product from the thin-layer chromatography plate and hydrolysing it in 6 normal hydrochloric acid for 16 h or by reacting the split product with dansyl reagent and then hydrolysing it. The identity of the heptapeptide product of the reaction of bradykinin with kininase II was established by comparing its migration in peptide mapping with the heptapeptide obtained after digesting bradykinin with a mixture of carboxypeptidase A and B (ref. 6).

Kininase II did not act as a transferase because when Arg and Ac-Ser-Pro-Phe-OH were incubated with the enzyme, no Phe-Arg spot was observed after the incubation. Thus the enzyme did not transfer phenylalanine from the substrate to arginine to create the dipeptide. Kininase II preparations still contained a dipeptidase impurity which hydrolysed Phe-Arg on prolonged incubation.

Kininase II was further characterized in biological studies when the inactivation of bradykinin was measured on the isolated rat uterus. Here 0.1–0.3 mg protein of enzyme/ml. was incubated with 3.3  $\mu$ g of bradykinin in a 0.1 molar *tris*, pH 7.4, at room temperature. Samples were withdrawn every 5 min, diluted and assayed on the isolated organ.

Table 1. INHIBITION OF THE INACTIVATION\* OF BRADYKININ BY KININASE I AND II OF HUMAN PLASMA

Inhibitor	Concentration (moles/l.)	Relative degree of inhibition Kininase I	Kininase II
CdSO <sub>4</sub>	1 $\times 10^{-3}$	++	0
HgCl <sub>2</sub>	1 $\times 10^{-3}$	++	++
EDTA	3 $\times 10^{-3}$	++	++
1,10-Phenanthroline	1 $\times 10^{-3}$	++	++
$\epsilon$ -amino- <i>n</i> -caproic acid	3 $\times 10^{-3}$	+	0
H-Phe-Arg-OH	1 $\times 10^{-2}$	++	++
Arginine	3 $\times 10^{-3}$	++	0
Trasyolol	125 $\mu$ mol.	0/+	0

\* Inactivation of bradykinin was measured on the isolated rat uterus.

++, Complete inhibition; +, partial inhibition; 0, no inhibition.

Table 1 compares the inhibition of kininase I (carboxypeptidase N) and kininase II by various compounds. The data indicate that the pattern of inhibition for two kininases is different. Arginine,  $\epsilon$ -amino-*n*-caproic acid and cadmium sulphate inhibit kininase I only. Kininase II is remarkably resistant to cadmium sulphate, while kininase I is strongly inhibited by that compound. It was shown that the esterase activity of carboxypeptidase N is inhibited by 50 per cent by a  $2 \times 10^{-7}$  molar concentration of the metal<sup>4</sup>. Both kininases are inhibited by the dipeptide H-Phe-Arg-OH, by HgCl<sub>2</sub> and by chelating agents. Although kininase II acts as endopeptidase (peptidyl peptide hydrolase), it is inhibited by EDTA and by 1,10-phenanthroline which suggests the necessity of the presence of a metal co-factor in the enzyme. Trasyolol, the inhibitor of various proteolytic enzymes, was inactive with kininase II.

Kininase II has properties similar to those of a microsomal enzyme which we have isolated from the kidney of a pig<sup>6,7</sup>. This enzyme, named peptidase P, cleaves the same bond in bradykinin as does kininase II of blood plasma.

It has been suggested that components of the kallikrein-kinin system occur in two different forms in plasma.

Plasma of various origin contain two kininogens<sup>8,9</sup>, two kallikreins<sup>10,11</sup> and two kallikrein inhibitors<sup>12</sup>. Our findings indicate that there are also two kininases present in human plasma. Kininase I is carboxypeptidase N<sup>2,13</sup> which is inhibited differently from kininase II. Kininase I cleaves the Phe<sup>8</sup>-Arg<sup>9</sup> bond of bradykinin; kininase II inactivates the peptide by hydrolysing the Pro<sup>7</sup>-Phe<sup>8</sup> link.

## RADIOBIOLOGY

### Distant Mutagenic Effects of Ionizing Radiation in Mammals

WHEN plant and animal tissues are irradiated with X- and  $\gamma$ -rays, humoral factors are formed which may have a mutagenic effect<sup>1-7</sup>. Mutagenic factors have also been found in irradiated organic growth media<sup>1,8-10</sup>. Here we report the findings of an investigation of the mutagenic effect of humoral toxic factors which appear in mammalian tissues after X-ray irradiation.

*The first experiments.* CC57Br male mice, 2–3 months old, were irradiated with X-rays (1,500 r. at 30 r./min) while their heads were screened by means of a thick-walled lead hemisphere. Mice of the same strain, sex and age were taken as controls and either subjected to the same manipulations without irradiation or irradiated fully screened. In all, one hundred mice were used in this experiment<sup>2</sup>. Twenty-four hours after irradiation, the animals were killed and their corneas were fixed in Carnoy liquid and stained with Behmer haematoxylin. The frequency of anaphases and telophases with bridges and fragments in the corneal cells was estimated. When mice were irradiated with their heads screened, the frequency of corneal cells with chromosome aberrations increased seven times more than those of the control animals which were completely protected by the lead shields and ten times more than the intact group (see Fig. 1).

*The second experiments.* With a radiation dose of 1,500 r., the irradiated part of the body can be considered as a source of "reflected radiation" which acts along the longitudinal axis of the body through the screened head and delivers radiation to the cornea at a dose of  $\approx 10$  r. In

Table 1. MUTAGENIC ACTION OF THE EXTRACTS FROM TISSUES OF IRRADIATED ANIMALS

Experimental animals	Series of experiments	Animals	Cornea		Per cent of aberrant mitoses	Animals	Bone marrow		Per cent of aberrant mitoses
			Normal mitoses	Aberrant mitoses			Normal mitoses	Aberrant mitoses	
Non-inbred albino rats	Intact control	14	8,847	7	0.04 ± 0.02	14	3,673	173	4.6 ± 0.32
	Injection of the extract from the tissues of intact rats	23	15,806	21	0.09 ± 0.02	22	5,891	253	4.3 ± 0.36
	Injection of the extract from the tissues of irradiated animals	24	14,638	61	0.42 ± 0.03	24	6,470	378	5.8 ± 0.88
CC57Br male mice	Intact control	25	12,130	0	0	Double dose of extract			
	Injection of extract from brain tissues of intact mice	10	2,823	0	0	9	3,751	2	0.02 ± 0.03
	Injection of extract from brain tissues of irradiated mice	57	15,533	37	0.24 ± 0.08	10	1,747	8	0.35 ± 0.09

order to rule out the possibility of reflected irradiation, the following experiment was carried out. Non-inbred albino rats and CC57Br mice were irradiated with a dose of 1,500 r. Twenty-four hours later, the animals were killed and their bodies and brains minced in cold phosphate buffer (pH 7.3) (ref. 3). Extracts were then prepared in cold aqueous saline and injected intravenously into rats and intraperitoneally into mice. Control animals received extracts from non-irradiated donors. Twenty-four hours later the eyes of the animals were enucleated, and parts of the femur and tibia near the knee were also resected from the rats. From the material obtained in this way, preparations of cornea and bone marrow were made and the number of cells with chromosomal aberrations was counted. Table 1 shows that there is a significant increase in the number of cells with chromosomal aberrations in the bone marrow and cornea of mice which have been injected with extracts from the whole bodies

Table 2. EFFECT OF DIFFERENT DOSES OF IRRADIATION ON THE MUTAGENIC PROPERTIES OF THE BRAIN EXTRACT FROM MICE

Experimental variants	Animals	Normal mitoses	Aberrant mitoses	Per cent of aberrant mitoses	Per cent of animals with negative results
Extract from intact donors	10	2,823	0	0	100.0
Extract from the brain tissues of the irradiated mice in dose of					
750 r.	11	2,334	0	0	100.0
1,500 r.	57	15,533	37	0.24 ± 0.08	42.1
3,000 r.	11	2,208	5	0.21 ± 0.09	72.7

and from the brains of irradiated mice. Extracts from the liver, spleen, testes, jejunum, fatty tissue and blood of irradiated animals did not produce any significant mutagenic effect.

The selective mutagenic activity of the irradiated brain as compared with other organs does not seem to be

related to the chemical specificity of the cells of the central nervous system because extracts from the *in vitro* irradiated mouse brain had no visible effect on the chromosomes of the cells of recipient animals. This indicates the important part played by the metabolic processes of the whole organism in the formation of "radiotoxins".

The mutagenic effect increased when the dose of the extract injected was doubled. The mutagenic activity of the extract did not change when animals were irradiated with a dose of 3,000 r., and a dose of 750 r. had no effect at all (Table 2).

There was considerable variability in the response of animals to similar amounts of mutagen. The decrease in the mutagenic effect produced when extracts from different organs of irradiated animals were used instead of whole body extracts also varied considerably (Table 3).

*The third experiments.* In the experiments reported so far, the mutagenic effect of the saline tissue extracts from irradiated animals resulted from the interaction of mutagenic agents with a complex set of factors within the organism. It was thus of interest to study this phenomenon on a less complicated model, that is, on the chromosomes of human leucocyte cultures.

In these experiments<sup>4</sup>, we used the same concentration of extract calculated for 1 ml. of culture medium. The extract was passed through a bacterial filter and then introduced into the leucocyte culture at the sixtieth hour of growth, that is, almost at the end of the premitotic stage<sup>11</sup>. We have studied 362 metaphase plates of two women 23 and 32 years old and a man 27 years old, all of them with a normal karyotype. The experiment was divided into three parts: (1) intact control; (2) leucocytes

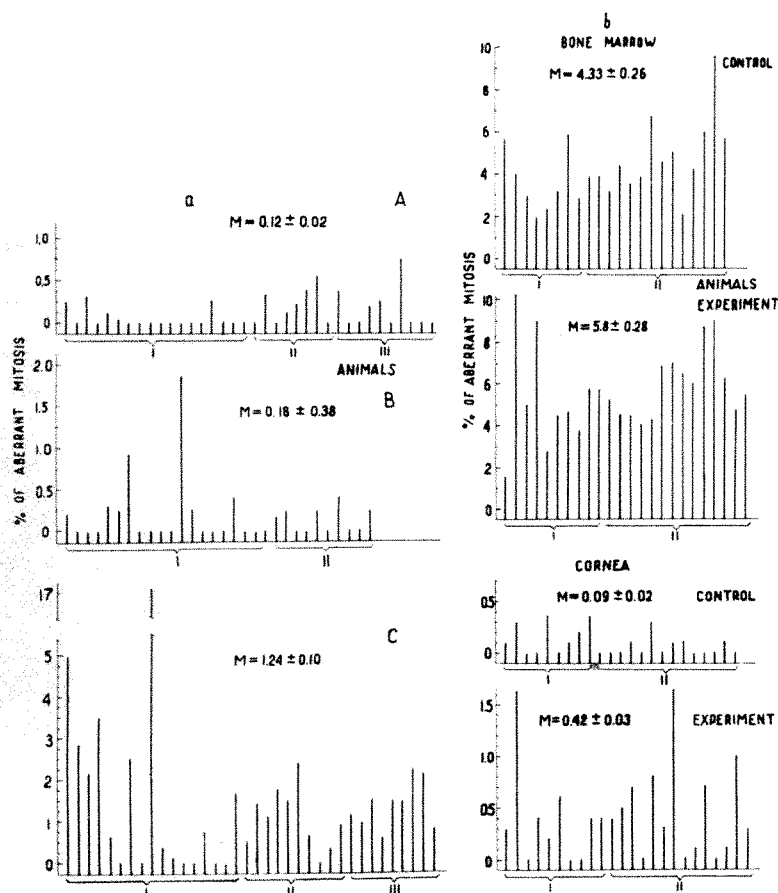

Fig. 1. Histogram of individual variability in the reaction of animals to the mutagenic action of the ionizing radiation. a, Screening of head. A, Intact control; B, screened control; C, screened head. b, Injection of salt-water extracts. I, II, III, Animal test groups.

Table 3. INCREASE IN DISAGREEMENT OF THE DATA FROM THE FIRST AND SECOND EXPERIMENTS (CORNEA)

Results/Method	Shielding of the head of mice	Extract from the whole bodies of irradiated rats	Extract from brain tissues of irradiated mice (1,500 r.)	Double dose of extract from brain tissues
Percentage of aberrant mitosis	1.24 ± 0.10	0.42 ± 0.03	0.24 ± 0.08	0.35 ± 0.09
Percentage of animals with negative results	20.0	25.0	42.1	72.8

Table 4. EFFECT OF BRAIN EXTRACT ON CHROMOSOMES OF LEUCOCYTES OF HUMAN PERIPHERAL BLOOD

Experimental variants	Number meta-phases	Chromosome aberrations					
		Aberrant metaphases		Acentric fragments		Dicentric	
		<i>M</i>	%	<i>M</i>	%	<i>M</i>	%
(1) Intact control	139	1	0.7	0	—	1	1.2
(2) Incubation of leucocytes with extract from intact mice tissue	123	7	5.7	6	4.8	1	0.8
(3) Incubation with extract from tissues of irradiated mice	100	13	13.0	12	12.0	1	1.0
$\chi^2 \geq 10.8$ ; $P = 0.999$ .							

$\chi^2 > 10.8$ ;  $P = 0.999$ .

incubated with intact mouse brain extract; (3) leucocytes incubated with the brain extract from mice which had been irradiated with 1,500 r. It can be seen from Table 4 that the frequency of spontaneous chromosome aberration in healthy donors was 0.7 per cent (out of 140 plates only one was found to have one dicentric). In experiment 2, 0.8 per cent of cells contained dicentrics and 4.8 per cent had acentric fragments. In experiment 3, the mutagenic effect of the tissue extract from irradiated animals was manifested by an increase to 13 per cent in the frequency of cells with chromosomal aberrations. These aberrations were mainly acentric fragments (12 per cent). All the aberrations in these experiments occurred in chromosomes and seemed to involve chromosomal breakages at secondary constrictions and in the region of the centromere—the heterochromatin nature of this tends to make them vulnerable to different extrinsic factors<sup>12-14</sup>.

Various hypotheses have been proposed to explain the mechanisms by which chromosomal breakages are formed after the irradiation of distant parts of the body. None of them can be considered proved, however, and the extension of this phenomenon is not yet clear.

In studying the leucocyte aneuploidy in our third experiment, we found that when the cells are incubated with extracts of irradiated tissues, hyperploid plates occur three times as frequently as in the intact control. The causes of this phenomenon are being studied.

## Effect of Previous X-irradiation on the Response of Brain to Injury

THE normal adult mammalian central nervous system shows no early or late morphological effects after a single dose of X-irradiation up to 1,000 rads<sup>1,2</sup> and even with doses of 2,000–4,000 rads there is a delay of many months before damage appears<sup>3,4</sup>.

In spite of this absence of morphological change after moderate doses of radiation we have shown that the cerebral glial reaction to injury is diminished after both small and larger doses (200–4,000 rads) and, furthermore, that this change seems to be independent of the time between irradiation and injury.

Brains of Sprague-Dawley rats, of both sexes, 3–4 months old were irradiated, under chloral anaesthesia (300 mg/kg intraperitoneally), to single doses of X-rays of 200–4,000 rads. Irradiation was given laterally to both cerebral hemispheres through a semi-circular port of diameter 18 mm, in 2.5 mm of lead shielding. Doses were given at 90–95 r./min, 220 kV, 15 mamp, with 0.5 mm of copper and 1.0 mm of aluminium as added filtration.

At intervals of between 3 days and 6 months after the irradiation a small superficial area of the brain was injured by freezing through the calvarium. This method was used because it gave regular results without the necessity of opening the skull and thereby avoiding the risk of infection. For this a cooling device was used which consisted of a copper tube, filled with a mixture of solid carbon dioxide and alcohol, at one end of which there was an applicator tube 3 mm in diameter. This tube was placed in contact with the exposed left parietal bone of the skull for a period of 15–20 min depending on the size of the animal. A single intraperitoneal injection of 1 per cent w/v trypan blue (0.5 ml./100 g body weight) was administered at the time of injury so that the exact location of the lesion was obvious when the brains were removed 1 week later.

The animals were killed 7 days after injury with an overdose of sodium pentobarbitone ('Nembutal'). The cerebral hemispheres were removed and fixed in 1 per cent acetic acid in 10 per cent formal saline. The slice of brain containing the centre of the lesion was slowly dehydrated in alcohols and embedded in paraffin wax. Sections 5  $\mu$  thick were cut and stained with Ehrlich's haematoxylin and eosin and mounted in the usual way.

The normal response to this freezing injury was necrosis followed by cell division and infiltration commencing at the periphery of the lesion. This was clearly marked at 3 days, and 7 days after the injury the saucer shaped area was uniformly populated with cells (Fig. 1). They were approximately 2.5 mm in diameter and 0.5–1.0 mm deep.

Fig. 1. Lesion on the left cerebral hemisphere of the brain of the rat, indicating the four areas (0.086 x 0.086 mm) used for cell counts, where the lesion is 0.5 mm thick.

Fig. 2. Cell counts/unit area of lesion, expressed as percentage of the controls, plotted against the dose of 220 kV X-rays.

To minimize subjective errors cell counts were made to the following standard procedure. Counts were always made in an area where the lesion was 0.5 mm thick. Using a squared graticule eyepiece and an oil immersion lens (magnification 1,050) cells were counted in four consecutive areas 0.086 × 0.086 mm, perpendicular to the surface (Fig. 1). The number of cells was estimated by counting to the nearest whole nucleus found within the graticule area.

Up to five consecutive serial sections of each lesion were mounted on a slide and of these a minimum of two sections were counted. The mean number of cells counted in each section for controls was 230.

The results, for rats irradiated 3 days before injury, are shown in Fig. 2. The numbers of cells/unit area are expressed as a percentage of the non-irradiated controls.

With selected doses we varied the period between irradiation and injury and observed a similar reduction in the cellular response, although so far the numbers of animals in these groups have been small (Table 1).

Exposure dose (r.)	Cell counts/unit area of lesion as percentage of control			
	Latent period between irradiation and injury			
	3 days	3 weeks	3 months	6 months
200	84.5 ± 1.4 (5)	84.3 ± 2.5 (3)	81.9 (2)	—
400	75.5 ± 1.6	—	—	68.5 (2)
2,000	61.1 ± 3.5 (5)	62.5 ± 2.5 (4)	58.5 (2)	62.5 (2)

Results are expressed as a percentage of controls, with standard errors when three or more animals were used. Figures in brackets indicate the number of animals used in each group.

The simplest explanation of this is that glial cells do not show radiation damage until they are stimulated to divide, when they either fail to divide or die. This "storing up" of radiation damage is possibly caused by the slow turnover of glial cells in normal conditions, so that replacement does not take place to any extent. Similar examples can be cited in such organs as the liver, skin and thyroid<sup>5-7</sup> where the radiation damage can be accelerated by the introduction of factors which influence the rate of mitotic activity. The observations<sup>8</sup> that the latent period before death after irradiation of the spinal cord could be greatly reduced by hypertension could have a similar basis.

The hypothesis that previously irradiated local glial cells die on attempting cell division is dependent on the assumption that most of the cells originate endogenously. The findings that a considerable number of the macrophages in brain lesions are haematogenous<sup>9</sup> seem to dis-

agree with our results. Thus further work is in progress to determine whether our results can be completely explained by a reduction in local glial cell proliferation, or whether some more complicated mechanism may be operating.

## BIOLOGY

### Paraquat and Sterility of Hen's Eggs

Dunachie and Fletcher's observation that paraquat at concentrations above a threshold level of 0.1–0.15 p.p.m. —about 5–7.5 µg/egg—is highly toxic to hen's eggs may seem alarming. As the second letter from ICI shows, however, in order to get 0.1 p.p.m. into an egg by feeding a fowl rather than with a syringe, it must be ingested at a concentration of 40 p.p.m., four times the concentration that ICI recommend for proper crop spraying.—Editor, *Nature*.

### Effect of Some Herbicides on the Hatching Rate of Hen's Eggs

In a previous communication<sup>1</sup> we gave hatching rates obtained after the injection, in various dosages, of a number of insecticides into hen's eggs, using the method of McLaughlin *et al.*<sup>2</sup>. The investigation has now been extended to test a number of herbicides.

Pesticides identified as contaminants in birds or their eggs in the wild have all been, so far as we are aware, organochlorine insecticides. Yet it has been found<sup>3</sup> that a number of herbicides show considerable persistence in the soil and should thus be susceptible to passage along a food chain and accumulation in animal tissues. As in our previous work, eggs have been treated in batches of twenty-five. Hatching rates, given in Table 1, have been expressed as percentages (rounded to the nearest 10 per cent) of controls, injected with solvent only. The solvent used has usually been acetone; occasionally the herbicide was brought into solution as the hydrochlorides and this has been indicated in the table. Aminotriazole and atrazine were injected in methanol; diquat, ioxynil and paraquat in water. The nomenclature of the compounds is that given in Woodford and Evans<sup>4</sup>.

In contrast with some of the insecticides, chiefly organophosphorous compounds, none of the herbicides tested produced deformities, though mecoprop, 2,4-DB, MCPA and MCPB, all chlorinated phenoxyacids, caused

Table 1

1. Dose given: 200 p.p.m. = 10 mg/egg (selected compounds only).

Percentage hatch	
100	Dalapon
90	Atrazine.HCl, chlorpropham
80	Mecoprop, dicamba, prometryne
50	2,4 D, TBA
30	Monolinuron, linuron
20	MCPA, MCPB
0	Desmetryne, dichlorprop

## 2. Dose given: 100 p.p.m. = 5 mg/egg (all compounds)

Percentage hatch	
100	Atrazine.HCl, chlorphencarb, dalapon, MABSC*, monolinuron, prometryne, simazine.HCl
90	Dicamba, TBA
80	Mecoprop, aminotriazole.HCl, chlorpropham
70	2,4 D, 2,4 DB, dichlorprop
60	Linuron
50	MCPA, MCPB, desmetryne
10	Diquat, prefix
0	Bromoxynil, DNOC, ioxynil, paraquat, pentachlorophenol

## 3. Dose given: 10 p.p.m. = 0.5 mg/egg (all compounds except prometryne and desmetryne).

Percentage hatch	
100	Aminotriazole.HCl, atrazine.HCl, chlorphencarb, chlorpropham, dalapon, ioxynil (10 per cent at 25 p.p.m.), linuron, MABSC*, MCPA, MCPB, monolinuron, prefix (50 per cent at 50 p.p.m.), simazine.HCl
90	2,4 D, dicamba, dichlorprop, mecoprop, TBA
80	2,4 D, pentachlorophenol (50 per cent at 50 p.p.m.)
70	Bromoxynil
30	DNOC (0 per cent at 20 p.p.m.; 80 per cent at 5 p.p.m.)
10	Diquat (60 per cent at 5 p.p.m.)
0	Paraquat (0 per cent at 0-25 p.p.m.; 40 per cent at 0-15 p.p.m.; 100 per cent at 0-1 p.p.m.)

\* Methyl-4-aminobenzene sulphonylcarbamate.

feather blanching. The most disturbing results are those for paraquat, which gives a heavy mortality even at 0-15 p.p.m., death occurring during the first day or two of development. By injecting a dose of 1 p.p.m. into separate batches at intervals after the commencement of incubation, we obtained a 20 per cent hatch at 2 and 4 days, but a hatch of 80 per cent and above thereafter, to the sixteenth day. When 10 p.p.m. was given on the tenth and fourteenth day, however, mortality in the later stages of development was heavy.

### Production and Viability of Eggs from Hens treated with Paraquat

IN the communication from Dunachie and Fletcher<sup>1</sup> it is shown that when paraquat is injected into fertile hen's eggs to give a final concentration greater than approximately 0.1 p.p.m. the subsequent rate of hatching was reduced. Because hens may eat food containing residues of paraquat from previous sprayings I made the following experiment to determine whether the amount of paraquat likely to be present would cause similar effects.

One hundred and fifty chickens, of a hybrid white leghorn strain, just past their period of maximum lay, were housed in six separate pens in one house on deep litter. Three of the pens each contained twenty-five control birds to which no treatment was given; the other three pens were similar except that the birds were given water containing 40 p.p.m. of paraquat as the dichloride salt. All the birds had free access to water and food, a record being kept of their weekly intakes. The treatment was continued for 14 days, after which time no paraquat was given to the treated group and data were collected for a further 14 days. The eggs which were laid were totalled daily, marked with the pen number and the day of laying, and stored. At the end of each week all the

eggs laid, with the exception of those cracked or misshapen, were transferred to the hatchery. A sample of three eggs per pen on alternate days was taken for analysis for paraquat by a modification of the method of Calderbank and Crowdy<sup>2</sup> and Calderbank and Yuen<sup>3</sup>. At the end of 18 days infertile eggs were rejected, their total and identification numbers being recorded. After 21 days the number of chicks hatched was counted and the unhatched eggs identified. The chicks were examined for abnormalities and then observed for a further 10 days.

Table 1. AVERAGE NUMBER OF EGGS LAID IN EACH PEN EACH WEEK

Period	Number of eggs (mean $\pm$ S.D.)	
	Control	Treated
Pre-experimental period	114 $\pm$ 12.5	106 $\pm$ 12
Week 1	96 $\pm$ 4	94 $\pm$ 15.5
Week 2	110 $\pm$ 9	93 $\pm$ 15
Week 3	107 $\pm$ 4	94 $\pm$ 13
Week 4	107 $\pm$ 4.5	110 $\pm$ 15

Table 2. ANALYSIS OF HATCHING RESULTS FROM EGGS

				No. hatched	No. abnormal eggs
				No. set (per cent)	No. set (per cent)
Week 1 and 2	Laid	Set	Fertile		
Control	619	522	483	88.4	17.2
Treated	561	465	414	83.5	24.3
Week 3 and 4					
Control	642	557	516	85.3	19.9
Treated	613	543	491	84.3	14.9

Table 1 shows the average weekly egg production of the treated and control groups. Although there was a fall in egg production during treatment the numbers of eggs produced by the treated group do not differ significantly from those of the controls. Table 2 gives the hatching results from the two groups in two periods of 14 days. The heading "abnormal eggs" includes those eggs which were infertile, did not hatch or produced an abnormal chick. While there is no difference between the hatchability of the two groups, there is a slight but significant difference ( $P = 0.02$ , Student's  $t$  test) between the numbers of abnormal eggs produced. The treatment appeared to have no significant effect on the food and water consumption of the hens nor the number or type of abnormality in the chicks. Fig. 1 shows that the amount of paraquat found in the eggs rises to about 0.1 p.p.m. and subsequently declines, being below the limits of detection 6 days after the cessation of treatment.

The maximum amounts of paraquat that have been found on food crops after proper spraying are 10 p.p.m., and normally the residues are much below this figure (ICI, internal report). Furthermore, experiments in this laboratory on other species indicate that a quantity of paraquat mixed with food is less toxic than the same amount given as a solution. Thus, although in this study with the concentrations used a small effect of paraquat on the chick embryo has been shown to occur, confirming the results of the Strathclyde workers, I feel that with the greatly reduced exposure of normal farming practice such an effect would be negligible and would be no hazard to poultry or consumers.

Fig. 1. The amount of paraquat found in eggs from hens given 40 p.p.m. paraquat in their drinking water (mean  $\pm$  S.E.). The treatment was stopped after the fourteenth day. The amount of paraquat in the control eggs was below the limit of detection (0.005 p.p.m.).

I thank Sterling Poultry Products, Ltd., for their co-operation in carrying out the laying trial, and Professor W. W. Fletcher and Mr J. F. Dunachie for telling me of their results before publication.

### Distribution of *Biomphalaria* Species in Sudan

INTESTINAL bilharzia (caused by the trematode *Schistosoma mansoni*) is transmitted by snails of the genus *Biomphalaria*. A survey has recently been conducted to determine the distribution of these snails in the Khartoum and Blue Nile provinces of Sudan.

The occurrence of *Biomphalaria alexandrina* (Ehrenberg) has until now been recorded only from Lower Egypt<sup>1</sup> but the present survey shows that this species is frequently present in Sudan. The distribution in the White Nile appears to extend from the dam at Jebel Aulia (50 km south of Khartoum) to at least as far south as Kosti (300 km south of Khartoum). High populations were found particularly among *Eichornia* (water hyacinth) plants and to a lesser extent in pump irrigation schemes. This species was also found on the west of the Gezira irrigation scheme (taking water from the Blue Nile) but its distribution east of this is uncertain.

*Biomphalaria sudanica* (Martens) also appears to have a wider distribution than formerly recognized. High populations of this species were found at Shambat, a pump scheme 8 km north of Khartoum on the main Nile, and at various points in the White Nile between Kosti and Khartoum. Previously<sup>2</sup>, it had been found no farther north than Kosti. *Biomphalaria pfeifferi* (Krauss), while common throughout the Gezira and pump schemes from the Blue Nile, was not found in the White Nile or its associated irrigation schemes.

It can be concluded from these observations that the distribution of the snails is changing rapidly. Presumably the northwards extension of the distribution of *B. sudanica* has been influenced by a similar extension of *Eichornia* since 1958 (ref. 3) but the reasons for the southwards movement of *B. alexandrina* are obscure. Measures to control bilharzia in Sudan will need to take the present complex distribution of snails into account and recognize that snails will rapidly move back into controlled areas.

### Effect of Carbon Monoxide on Metabolism of Insecticides *in vivo*

THERE have recently been several reports which indicate that the oxidative metabolism of drugs by liver microsomes involves a cytochrome-like pigment usually referred to as *P-450* (refs. 1 and 2). This pigment, which is characterized by the difference spectrum observed when microsomal suspensions reduced either with hydrosulphite or

Fig. 1. Effect of carbon monoxide and oxygen tension on formation of dieldrin in houseflies treated with aldrin. ○, Flies kept in air; ▽, flies kept in 40 per cent carbon monoxide, 20 per cent oxygen, 40 per cent nitrogen; □, flies kept in 90 per cent nitrogen, 10 per cent oxygen; △, flies kept in 90 per cent carbon monoxide, 10 per cent oxygen.

with NADPH are saturated with carbon monoxide, has recently been found in microsomes from the housefly *Musca domestica* (vicina strain)<sup>3</sup>. Furthermore, the inhibition by carbon monoxide of the epoxidation of aldrin and the partial reversal of this inhibition by light supports the view that *P-450* is involved in epoxidation by fly microsomes *in vitro*. Similar evidence has been produced to support the view that this pigment is involved in the metabolism of drugs by microsomes from rat liver<sup>2</sup>. Evidence for the role of a reaction in the metabolism of insecticides *in vivo* which is sensitive to carbon monoxide has not, however, been reported.

The relative affinities of carbon monoxide and oxygen to haemoglobin, *P-450* and cytochrome oxidase are 200:1, 1:1 and 1:10, respectively<sup>4</sup>. The housefly, in common with other insects, does not rely on haemoglobin for the transport of oxygen and so it is likely to survive in a mixture of carbon monoxide and oxygen which would inhibit reactions involving *P-450*. Thus it would seem that insects may be particularly suitable animals in which to examine the effect of carbon monoxide on the metabolism of foreign compounds *in vivo*. The epoxidation of the insecticide aldrin is a reaction which is well suited for this purpose because in the housefly there is little evidence of further metabolism of the epoxide (dieldrin)<sup>5</sup>.

Four-day-old female houseflies *Musca domestica* (vicina strain), resistant to dieldrin, were treated individually with 2 µg of aldrin in 2 µl. of acetone. Groups of ten flies were confined in glass cylinders of 1 l. capacity which had previously been filled with an appropriate mixture of carbon monoxide, oxygen and nitrogen. They were supplied with sucrose and water in glass tubes plugged with cotton wool and held at a temperature of 25°C. When exposed to a gas mixture consisting of 90 per cent carbon monoxide and 10 per cent oxygen the flies were unable to fly but were not completely immobilized. Separate experiments had shown that after being exposed to this gas mixture for 16 h flies recovered completely when the gas mixture was replaced by air. In a gas mixture consisting of 20 per cent oxygen, 40 per cent carbon monoxide and 40 per cent nitrogen flies, behaved in a normal manner for at least 48 h.

At appropriate times after treatment with aldrin the flies were removed from the cylinders and immediately rinsed with two 3 ml. volumes of acetone in order to remove external aldrin. They were then homogenized and extracted twice, first with 4 ml. and then with 3 ml. of acetone. Four ml. of water and sodium sulphate was added to the acetone extract which was then extracted with two 4 ml. volumes of petroleum ether. The aldrin

and dieldrin in the petroleum ether extract was assayed by gas-liquid chromatography. Flies treated with aldrin and confined in cylinders containing either air or a mixture of 10 per cent oxygen and 90 per cent nitrogen were used as controls.

The amount of dieldrin, expressed as a percentage of the total insecticide (aldrin plus dieldrin), found inside the flies is shown in Fig. 1. In flies exposed to the gas mixture containing 40 per cent carbon monoxide, 20 per cent oxygen and 40 per cent nitrogen, the rate of formation of dieldrin is markedly lower than in flies kept in air. The rate of dieldrin formation is even lower when the carbon monoxide: oxygen ratio is increased to 9:1. This is probably due in part to lack of oxygen because the rate of dieldrin formation in the controls kept in 90 per cent nitrogen and 10 per cent oxygen is less than in those kept in air.

Similar experiments were carried out with larvae aged 4 days from the same strain of flies. The larvae were treated individually with 2  $\mu$ g of aldrin in 2  $\mu$ l. acetone before being exposed to the appropriate gas mixture and were rinsed and extracted as already described for the adult flies. The dieldrin in the larval extract, again expressed as a percentage of the internal aldrin plus dieldrin, is shown in Fig. 2. Here again the rate of dieldrin formation is reduced in insects which are exposed to gas mixtures containing carbon monoxide. This reduction cannot be attributed to a lack of aldrin, for in none of the experiments with carbon monoxide was the concentration of aldrin within the insects less than that in the controls.

Although the epoxidation of aldrin probably results in an increase in toxicity, the oxidative metabolism of many insecticides results in detoxication. The toxicity of two such compounds to the housefly *Musca domestica* has been estimated in air and in a gas mixture consisting of 40 per cent carbon monoxide, 20 per cent oxygen and 40 per cent nitrogen. The insecticides chosen were carbaryl (1-naphthyl *N*-methylcarbamate) and a cyclodiene epoxide (1,2,3,4,9,9-hexachloro-1,4,4a,5,6,7,8,8a-octahydro-5,6-epoxy-1,4-methanonaphthalene) supplied by Dr G. T. Brooks. The toxicity of both compounds to this strain of fly is known to be enhanced by the methylenedioxyphenyl synergist sesamex<sup>6,7</sup>. Furthermore, the metabolism of both compounds by microsomes is inhibited by carbon monoxide (unpublished work of S. E. Lewis and of R. J. Kuhr).

Female houseflies, 4 days old, were treated individually with the insecticide in 2  $\mu$ l. of acetone before being confined in groups of twenty in cylinders containing either air or the 40 per cent carbon monoxide gas mixture. The flies were supplied with sucrose and water as described earlier

Fig. 2. The effect of carbon monoxide on formation of dieldrin in housefly larvae treated with aldrin.  $\square$ , Larvae kept in 90 per cent nitrogen, 10 per cent oxygen;  $\triangle$ , larvae kept in 90 per cent carbon monoxide, 10 per cent oxygen.

and held at a temperature of 25° C. The mortality was assessed on a count of dead flies made 24 h after treatment with various concentrations of the insecticides, and the  $LD_{50}$  estimated. When flies were treated with the cyclodiene epoxide and kept in air the  $LD_{50}$  was 2  $\mu$ g/fly—a value similar to that previously reported<sup>7</sup>; in the carbon monoxide mixture this was reduced to 0.5  $\mu$ g/fly. With carbaryl the  $LD_{50}$  for flies kept in air could not be estimated but exceeded 30  $\mu$ g/fly; in the carbon monoxide gas mixture the  $LD_{50}$  was reduced to 2  $\mu$ g/fly.

These data indicate that a component which is sensitive to carbon monoxide is involved in the metabolism of some insecticides *in vivo* and it can be argued from experiments *in vitro* (ref. 3 and unpublished results of Lewis and Kuhr) that this component is probably the microsomal cytochrome P-450.

### Electrophoretic Polarity exhibited by Amoeboid Cells of *Naegleria gruberi*

*Naegleria gruberi* is a small ( $\sim 15\mu$  diameter) free living cell which is able to transform reversibly from the amoeboid to the flagellate state<sup>1</sup>. The amoebae move by forming one or more lobose pseudopodia, any one of which may be considered to define a functional anterior end. It was observed, quite unexpectedly, in the course of electrophoretic characterization of the cell surface, that individual freely suspended amoebae manifest a transient local difference in mobility during pseudopodal protrusions, the anterior pseudopodal end having a higher negative mobility. While this suggests that the advancing pseudopod possesses a higher negative zeta potential, and thus higher negative surface charge density than the rest of the cell, it is open to alternative interpretations.

Cells were cultured on agar slopes, together with nutrient bacteria, and collected in 0.001 molar phosphate buffer, pH 6.8. Bacteria were separated by centrifugation from 10 ml. of 0.001 molar buffer, repeated three times. Cells were resuspended in the same buffer for mobility measurements. Earlier electrophoretic measurements were made in a cylindrical cell apparatus of the type described by Bangham *et al.*<sup>2</sup>, but most were performed in a rectangular cell apparatus fitted with a return tube as described by Lukiewicz and Korohoda<sup>3</sup>. In this apparatus a single cell may be kept under continuous observation for long periods of time, and electrophoretic mobility measurements made at desired intervals. Similar values were obtained with both instruments.

From electrophoretic measurements made at 20° C in 0.001 molar phosphate buffer, the mean mobility of amoeboid cells was calculated to be  $2.11 \pm 0.13 \mu/\text{sec/V/cm}$ . At this temperature the cells are active, frequently throwing out pseudopodia without net locomotion, while freely suspended. During mobility measurements a striking pattern of cellular behaviour was repeatedly observed: on applying the electrophoretic potential, a cell in the process of pseudopodal protrusion would be seen to rotate and become aligned in the external field, and this would result in migration of the cell under the

influence of the applied potential towards the anode, pseudopod foremost. On reversing the field (6 V/cm) the amoeba would, in about 5 sec, re-orientate by rotating through  $180^\circ$  (Fig. 1). Similar behaviour was also observed in pre-aggregation cells of the slime mould *Dictyostelium discoideum* Raper. Cellular polarity has previously been described by Korohoda<sup>4</sup>, who found an identical orientation in amoeboid cells of the slime mould *Physarum nudum* MacBride, the pseudopodal tip once again showing a higher negative mobility.

The different charge densities at anterior and posterior ends of *Naegleria gruberi* amoebae, which could account for the observed differential mobility, may be estimated very roughly by measuring the separate velocities, in the direction of the field, of front and rear extremities as the cell undergoes  $180^\circ$  rotation in a field of known strength.

During re-orientation, the mean distance travelled by the centre of a cell is, from mobility data, approximately  $63\mu$ , assuming a mean cellular diameter of  $15\mu$ . Thus in the course of re-orientation the back of the cell has moved  $(63 - 15) = 48\mu$  and the front has moved  $(63 + 15) = 78\mu$ , in the direction of the field. As a first approximation therefore the difference in mobilities of the front and back of a cell putting out a pseudopod could be accounted for by a charge difference in the ratio  $78 : 48$  or  $1.6 : 1$ .

In this simple treatment, the front and back ends of the cell are considered as two completely independent bodies the mobilities of which are determined by their separate charge densities. This analogy suffers from excessive simplicity. If one imagines a model dumb-bell with joined, rather than separate, spheres, where each sphere carries a different charge density, the slower sphere of lower charge density will tend to retard the faster, and vice versa, resulting in an underestimation of the difference in mobilities calculated on the assumption that the spheres have no mechanical influence on each other.

The possibility that orientation in the direction of motion could be merely a hydrodynamic effect due to cellular asymmetry was investigated and shown to be unimportant. Cells were suitably orientated by adjustment of the field polarity in the vertical apparatus, and then allowed to sediment under gravity alone, pseudopod downwards or pseudopod upwards. It was found that the cells sedimented, regardless of their initial orientation, without change in orientation.

Another interpretation of the reversal phenomenon which is much less simple to investigate stems from the following considerations. If the rear end has an effective radius of curvature of rather less than  $1\mu$  (due to surface undulations, for example), while the anterior pseudopodal surface has an effective radius of curvature of more than  $1\mu$ , then the zeta potential and hence the mobility would be different at either end. It is possible to calculate the true surface charge taking these factors into account. It can be shown that if the radius of curvature of the rear of the cell is less than  $400 \text{ \AA}$ , while that of the front is effectively infinitely large ( $1.0\mu$ ), the ratio of mobilities at the front and back of the cell would be  $1.6 : 1.0$ . Published electron micrographs<sup>5</sup> of *Naegleria gruberi* amoebae fixed while attached and moving, however, do not show any significant local differences in surface curvature. The smallest radii of curvature are of the order of  $0.5\mu$ , easily resolved at a magnification of  $2.7 \times 10^4$ , and these are not

restricted to any particular region, so it can be concluded that there is no evidence for believing that the observed mobility differences stem from curvature differences rather than localized surface charge differences.

Increase in local negative surface charge density during pseudopodal protrusion may provide a clue to the physiological basis of behavioural polarity in moving cells. This is particularly interesting, because changes in cell membrane surface potential can lead to cytoplasmic motile responses (ref. 6 and our unpublished work).

One of us (D. G.) was in receipt of a Nuffield research grant during the course of this work, and W. Korohoda held a British Council Scholarship at the Chester Beatty Research Institute.

### Cyclic Diquaternary Salts of 1,10-Phenanthroline as One Electron Transfer Agents related to Bipyridylum Herbicides

CERTAIN diquaternary salts of 2,2'- and 4,4'-bipyridyls are herbicides<sup>1</sup>. Their mode of action is thought<sup>2</sup> to be connected with their ability to be reduced to a stable radical cation, at a potential ( $E_0$ ) of about  $-0.35$  to  $-0.45$  V, by a one electron transfer which is reversed by oxygen. Diquaternary salts of 1,10- and 3,8-phenanthroline, where the nitrogen atoms are in the same relative positions as in 2,2'- and 4,4'-bipyridyls, have not so far been investigated as herbicides although it seems reasonable to expect that they too would give stable radical cations on reduction with one electron reducing agents. This communication reports results with diquaternary salts of 1,10-phenanthroline.

Before this investigation, no diquaternary salts of 1,10-phenanthroline had been reported. 1,10-Phenanthroline reacted readily, however, with boiling ethylene dibromide to give 5,6-dihydropyrazino(1,2,3,4-*l,m,n*)-1,10-phenanthroline dibromide; (I;  $n=2$ ) (ref. 3). It reacted similarly with 1,3-dibromopropane to afford 5*H*-6,7-dihydro(1,4)-diazepino(1,2,3,4-*l,m,n*)-1,10-phenanthroline dibromide (I;  $n=3$ ), which crystallized from aqueous ethanol as pale yellow crystals, melting point  $286^\circ \text{C}$  with decomposition. The structure of (I;  $n=3$ ) was confirmed by elemental analyses (all bromine ionic) and by the nuclear magnetic resonance spectrum in deuterium oxide with sodium 3-trimethylsilyl-1-propane-sulphonate as internal reference. The nuclear magnetic resonance spectrum consisted of a multiplet at  $\delta=8.55$ - $9.85$  p.p.m. (eight aromatic protons), a triplet centred at  $\delta=5.3$  due to the four methylene protons adjacent to the quaternary nitrogen atoms and a multiplet at  $\delta=3.55$  assigned to the two central methylene protons. As expected for derivatives of the rigid planar phenanthroline

Fig. 1. Re-orientation of *Naegleria gruberi* amoeba on reversing polarity of the electrophoretic field.

ring system, the ultra-violet spectra (Table 1) of the two diquaternary salts were almost identical (compare ref. 2).

The diquaternary salts each gave a deep red solution in water on treatment with zinc dust, the coloration being attributed to the radical cation of which (II;  $n=2$  or 3) is one of the many canonical forms. The presence of a high concentration of a stable radical was confirmed in each case by the observation that the nuclear magnetic resonance spectrum of the intensely coloured solution was of low intensity and was poorly resolved. When the reducing agent was removed and the solution was shaken in air, the deep colour discharged and the nuclear magnetic resonance spectrum of the compound (I;  $n=2$  or 3) returned, thus demonstrating the reversibility of the one electron transfer. On polarographic examination in 0.067 molar Sorensen phosphate buffers of pH 5.9, 6.8 and 8.04, compounds (I;  $n=2$ ) and (I;  $n=3$ ), at concentrations between 0.001 molar and 0.0015 molar, each gave a typical symmetrical one electron reduction wave with half-wave potentials of  $-0.53$  and  $-0.52$  V respectively, against a standard calomel electrode, independent of pH and concentration. The corresponding values of  $E_0$  are  $-0.28$  and  $-0.27$  V. Diquat dibromide was included in the experiments for comparison and gave, as before<sup>4</sup>, a value of  $E_0$  of  $-0.36$  V. The polarograms of the diquaternary salts of 1,10-phenanthroline did not reveal a clear-cut second reduction step as is observed with diquat<sup>4</sup> and paraquat<sup>5</sup>, the current gradually increasing as the applied voltage decreased. It is evident from these results that the diquaternary salts (I;  $n=2$  and 3) are reduced to radical cations more easily than diquat and paraquat and that the one electron transfer is largely reversed by atmospheric oxidation.

In herbicidal tests, the diquaternary salts of 1,10-phenanthroline at a high concentration desiccated green plant tissue in a manner typical of bipyridylum herbicides<sup>1</sup> although at practical rates of application (Table 2) they were clearly much inferior to diquat.

Table 1. ULTRA-VIOLET ABSORPTION SPECTRA OF DIQUATERNARY SALTS OF 1,10-PHENANTHROLINE

Compound	$\lambda_{\max}$ (m $\mu$ )	log $\epsilon$
(I; $n=2$ )	226, 279, 295, 308, 318	4.32†, 4.61, 3.81, 3.87, 3.78
(I; $n=3$ )	226*, 281, 298, 311, 322*	4.32, 4.59, 3.76, 3.83, 3.70

\* Shoulder.

† Extinction coefficients reported previously (ref. 3) were approximate.

Table 2. GREENHOUSE POST-EMERGENT HERBICIDAL TESTS OF DIQUATERNARY SALTS OF 1,10-PHENANTHROLINE

Compound	Rate (lb./acre)	Lin-seed	Herbicide evaluation				
			Buck-wheat	Mustard	Peas	Sugar beet	Barley
(I; $n=2$ )	8	0	0	1	1	10	0
	4	0	0	0	0	5	0
(I; $n=3$ )	8	1	2	3	1	10	1
	4	1	1	2	0	9	0
Diquat dibromide	4	10	10	10	10	10	10

Compounds were applied as foliar sprays. Herbicidal effects were estimated visually after 7 days on the scale, 10 = complete kill, 0 = no effect.

The discovery of herbicidal activity, although of a relatively low order, in diquaternary salts of 1,10-phenanthroline demonstrates that the toxic action of the diquat and paraquat type is not confined to diquaternary salts of bipyridyls as has been supposed<sup>2</sup>. It also strongly supports the view that the herbicidal action of the bipyridyls is associated with their reversible one electron transfer properties<sup>1,2,6</sup>. The reasons for the low activity of the phenanthroline diquaternary salts are probably connected with their relatively large values of  $E_0$  which presumably lie just outside the potential range of the biochemical electron transfer processes with which the bipyridylum herbicides are thought to interfere.

I thank Dr J. N. Phillips of the Division of Plant Industry, CSIRO, Canberra, for arranging the herbicidal tests reported in Table 2.

### Phytochrome in Red Alga, *Porphyra tenera*

THE marked stimulation of spore formation in the conchocelis phase of *Porphyra tenera* Kjellm. by short day (SD) conditions was first reported by Kurogi<sup>1</sup>. The ability of a short light interruption in the middle of a long dark period to simulate long day (LD) conditions has recently been shown, and it was therefore concluded that the response was a "genuine" photoperiodic response of the type common among flowering plants<sup>2</sup>. A rough action spectrum for the inhibition of the reproductive response by short light breaks has been determined, in an attempt to identify the pigment which mediates this photoperiodic response.

Culture methods for the conchocelis, and the techniques used for estimating growth and reproduction, have already been described<sup>2</sup>. The apparatus used for the irradiation of cultures with monochromatic light was similar to that described by Wilson and Schwabe<sup>3</sup> for similar work with *Lunularia*. A set of five interference filters was used, with peak transmissions at the wavelengths shown in Table 1 and an average waveband at 1 per cent transmission of about 70 m $\mu$ . The incident energy at each waveband was adjusted to about 90 ergs/cm<sup>2</sup>/sec.

All cultures received a main light period of 8 h of white light/day in a culture tank at 20° C. Nine different light break treatments were given at about the middle of the dark period, two cultures being used for each treatment. Five principal treatments consisted of a 60 min exposure to each of the five wavebands, and 30 min exposures to the red and far-red wavebands were also given. Two further treatments received 30 min of red followed immediately by 30 min of far-red, and 30 min of far-red followed by 30 min of red. Control cultures received no light break. The light break treatments were continued for eight

Table 1. SPORANGIA PRODUCTION IN RESPONSE TO LIGHT BREAKS OF DIFFERENT WAVEBANDS

Interference filters	Peak transmission (m $\mu$ )	Sporangial branches/0.01 ml. conchocelis			
		30 min treatments	60 min treatments	Mean	S.D.
Colour		Mean	S.D.	Mean	S.D.
Blue	446	—	—	4,753	669
Green	501	—	—	4,640	430
Yellow	564	—	—	3,900	550
Red	662.5	2,860	393	2,171	307
Far-red	737.5	4,304	930	4,496	507
Red/far-red		4,461	394	—	—
Far-red/red		2,746	357	—	—
SD Control		4,092	296	—	—

Each value represents the mean of five samples from each of two replicate cultures.

cycles (which is known to be sufficient for full induction<sup>3</sup>) and all cultures were then returned to LD conditions. Sporangia production was estimated 25 days after the beginning of SD treatment. The results are shown in Table 1.

It is evident that red was the only waveband which was effective as a light break, and that the inhibition of sporangia production caused by 60 min of red light was roughly twice that caused by 30 min of red. Far-red light was completely ineffective, even if irradiation was continued for 60 min. Far-red periods of 30 min, however, completely reversed the inhibitory effects of a preceding period of 30 min of red although it had no influence on subsequent red irradiation. Analysis of variance of the results showed that the overall variation caused by the treatments was significant at 0.1 per cent ( $F = 38.766$ , d.f. 9, 90), and that most of this variation could be attributed to the effects of red light. If the treatment mean square was partitioned between those treatments which received red, alone or after far-red, and all other treatments, the  $F$  values obtained were 103.150 (d.f. 3, 90) for the red treatments and 6.574 (d.f. 6, 90) for the others.

The photoreceptor pigment for both SD and LD photoperiodic responses in flowering plants has been shown to be the photomorphogenic pigment; phytochrome and phytochrome mediated responses have been found to exhibit a characteristic action spectrum in which the effects of red light are reversed by far-red light<sup>4</sup>. Attention was therefore concentrated on these regions of the spectrum and interference filters were selected to coincide with the absorption maxima of the two forms of phytochrome. The action spectrum which has been obtained for the SD photoperiodic response of *Porphyra* shows a peak in the red region of the spectrum, and the effects of red are completely reversed by subsequent far-red treatment. These results thus show clearly that phytochrome is involved in this response and that this pigment occurs in *Porphyra*.

There have been several previous demonstrations of phytochrome in lower plants such as mosses<sup>5</sup>, a liverwort<sup>3</sup> and two green algae<sup>6,7</sup>, but so far it has only been demonstrated in plants in which the green photosynthetic pigments predominate. This has led to the suggestion that phytochrome may be in the "evolutionary line in which chlorophylls A and B are the only light receptors in photosynthesis"<sup>8</sup>. This hypothesis must be discarded in the light of the present results. Because the presence of phytochrome can be demonstrated in an algal group the pigment composition of which differs so significantly from that of the Chlorophyta and the higher plants, it is tempting to speculate that it will also be found in other algal groups. Recent work on the structure of the chromophore of phytochrome<sup>9</sup> has revealed its similarity to the chromophores of the biliproteins, *O*-phycoerythrin and allophycoerythrin, both of which have been isolated from *Porphyra tenera*<sup>10</sup>. This similarity indicates that the Cyanophyta may well contain phytochrome, and that this pigment may therefore be basic to all photosynthetic organisms.

## Enzymes of the Ornithine-Urea Cycle in the Chimaera *Hydrolagus coliei*

THE chimaera *Hydrolagus coliei*, commonly known as the ratfish, is one of the few remaining members of the sub-class Holocephali. The chimaeras are the only survivors of a large and diverse Palaeozoic group, the bradyodonts<sup>1</sup>. The bradyodonts and elasmobranchs appear in the late Devonian as fossils of two apparently distinct groups<sup>1</sup>. Elasmobranchs and chimaeras share the ability to maintain large tissue concentrations of urea which serves an osmoregulatory function<sup>2</sup>. All the enzymes of the ornithine-urea cycle have been found in the elasmobranchs<sup>3-7</sup>, and in this group the ornithine-urea cycle is thought to be the most important pathway for the formation of urea<sup>8</sup>. The chimaeras have not been studied for the occurrence of any of the ornithine-urea cycle enzymes except arginase, which was found in both liver and kidney of *Hydrolagus coliei*<sup>9</sup>. The presence of arginase is insufficient evidence for the occurrence of the remaining enzymes of the cycle because it occurs in groups which apparently lack a complete ornithine-urea cycle<sup>10</sup>. The present investigation was undertaken to find out whether all the enzymes of the ornithine-urea cycle are present in the liver of the ratfish *Hydrolagus coliei*.

Ratfish were obtained by otter trawl from the waters of the San Juan Archipelago, Washington, and kept in large tanks of seawater until used. The methods for assaying the enzymes were those of Ratner<sup>11</sup> for argininosuccinate synthetase, and of Brown and Cohen<sup>12</sup> for the remaining four enzymes. Modifications of these methods are necessary for the ratfish because the large tissue concentrations of urea interfere with citrulline determination<sup>13</sup>. When the assay depended on measuring either the formation or disappearance of citrulline (in those assays for carbamoyl phosphate synthetase, ornithine carbamoyltransferase and argininosuccinate synthetase), the homogenized liver was treated with urease to break down urea already present. For the remaining two enzymes, argininosuccinate lyase and arginase, urea was measured both before and after incubation, and the difference in the two values was taken as a measure of the amount of urea formed.

Liver was homogenized 1:9 with ice cold water in a glass homogenizer with a 'Teflon' pestle. The homogenate was centrifuged at 650g for 5 min at 0°-4° C. Centrifugation in the cold caused a fairly good separation of the fat present; this could then be removed by aspiration. The remaining homogenate was either diluted or used directly for the various assays.

The occurrence of the enzymes of the ornithine-urea cycle was established in several ways. The enzymes were shown to be dependent on the same substrates and co-factors known to be required for full enzyme activity in elasmobranchs and other vertebrates. There was, for example, negligible activity of carbamoyl phosphate synthetase in the absence of a metal ion activator (manganese or magnesium ions). Also, a linear increase in the activity of each of the enzymes was found with both increased protein concentration and increased incubation time within certain experimental limits. Finally, boiled homogenate used in control determinations gave little or no activity.

Comparison of the concentrations found for the ornithine-urea cycle enzymes indicates that argininosuccinate synthetase, with an activity of  $0.235 \pm 0.088$   $\mu$ moles/mg of protein/h (mean value  $\pm$  mean deviation), is the rate limiting enzyme of the ornithine-urea cycle in the ratfish. This same pattern has usually been found in other vertebrates including the elasmobranch *Squalus acanthias* (my unpublished work). Ratfish arginase activity ( $38.7 \pm 10.4$   $\mu$ moles/mg of protein/h) was less than in most other vertebrates that have been studied<sup>7,10,14</sup>. In contrast, ornithine carbamoyltransferase activity ( $161 \pm 36$   $\mu$ moles/mg of protein/h) was at about the same level that it is in

many other vertebrates including man. The levels of activity of carbamoyl phosphate synthetase and argininosuccinate lyase were  $0.82 \pm 0.11$  and  $3.77 \pm 0.44$   $\mu$ moles/mg protein/h, respectively.

The presence of the ornithine-urea cycle in both elasmobranchs and chimaeras, and the osmotic importance of urea in these two groups indicate that their ancestors lived in a marine environment at the time when they diverged. A comparative study of these lower vertebrates may give insight into the primitive characteristics of the ornithine-urea cycle.

I thank Dr Robert L. Fernald for allowing the use of the Friday Harbor Laboratories, University of Washington, Drs Ingrith Olsen and Aubrey Gorbman for advice, and Dana Read for technical assistance. This work was supported in part by a grant from the US National Science Foundation.

## PSYCHOLOGY

### Spatial Orientation in the Blind

LITTLE is known directly about the ability of congenitally blind subjects to orient themselves in an unfamiliar environment. Senden<sup>1</sup> went to considerable lengths to document the apparently inherent and unsurmountable difficulties arising from an alleged absence of a "sense of space". It is clear, however, that the cases assembled by him did not as a whole show degrees of mobility which are more commonplace today. Having worked with a wide range of blind subjects during the past 5 yr we have become convinced that whatever difficulties congenitally blind subjects may experience in problems of spatial orientation are more likely to be caused by lack of experience than by blindness as such.

One test of spatial orientation is to ask subjects to move through an unfamiliar environment by means of a map. Tactual maps in particular have been employed in clinical tests for spatial orientation during the past decade (page 270 of ref. 2 gives a summary). We have been carrying out work with a range of "maps" for blind people during the past 18 months. We have already described these maps and some earlier work<sup>3</sup>, and a full report of our recent work will be published later. Here we wish to draw attention to one finding only.

Blind boys were asked to follow a route indicated on a tactual map and were required to solve two detour problems towards the end of their route. Of six boys (aged 14-15) who were either totally blind or had perception of light only, five were effectively blind from birth. They had been trained in the use of maps by one of their masters in accordance with a syllabus suggested by us. Fig. 1

Fig. 1. The route started at S and subjects were asked to walk as shown by the double line in the direction of the half-arrows. The dotted lines mark the blocks around which detours had to be made from detour points 1 and 2 respectively. Scale, 6 in. = 1 mile.

shows the route to be followed. It was indicated on the boys' map by small pins fitted almost flush at key points. Each boy was shown the map a few minutes before setting out and asked to trace the map with his fingers to the satisfaction of the experimenter. He then set off carrying his map, until he came to detour point 1 when the experimenter explained that "the road was up" and that a detour was required. The same drill was followed at detour point 2. At each detour point subjects were first asked to solve the problem on their map before having to carry out the appropriate manoeuvre. Subjects' performance was timed over various sections of the route and errors of mobility and/or map reading were noted.

A map reading error was a deviation from the prescribed route whether this was subsequently self-corrected or not. For each detour problem subjects were given one point for solving it unaided, half a point if the experimenter had to explain the principle involved, and no point if the experimenter had to explain the specific solution.

Table 1 shows the results. It is interesting that three other boys with relatively high degrees of residual vision took between 17 and 21 min for the same task. The errors made by subjects 3 and 6 were subsequently self-corrected. All but one of the subjects managed to solve the second detour problem without help from the experimenters.

To the extent that following a route from a tactual map and solving a detour problem is accepted as evidence of the ability to orientate oneself in space, we may claim to have demonstrated this ability with congenitally blind subjects. It is hoped that use of maps for the blind will not only serve a practical purpose but also contribute to a better understanding of the manner in which those born blind handle problems of spatial orientation. It should not be too difficult to design more complex problems requiring the use of dimensional in-

Table 1. SCORES FOR SIX BLIND GRAMMAR SCHOOL BOYS

## SOIL SCIENCE

### Nature and Distribution in Irish Soils of a New Soil Pigment

THE isolation of a green pigment (green humic acid) probably related to perylenequinone from widely distributed soils, chiefly podzols, has been described<sup>1</sup>. A pigment of the hydroxyanthraquinone type has now been found in a large number of Irish soils. Although hydroxyanthraquinones occur widely in plant roots and fungi<sup>2</sup> we have been unable to find any previous account of their isolation from soil.

The pigment may be readily obtained from dried soil (a) by Soxhlet extraction with chloroform or (b), more specifically, by extraction into the upper (acetone) layer of a 1:1 mixture of acetone and 2 normal aqueous sodium hydroxide. Pigment was isolated from *B<sub>h</sub>* horizon of the screen (Co. Wexford) podzol (which also contains green humic acid) by method (b); it was precipitated by acidification and purified by extraction into chloroform from which it crystallized spontaneously. A sample of 13 kg of soil gave 170 mg of crystalline (by X-ray diffraction pattern) pigment, melting point  $>360^{\circ}\text{C}$ . It was soluble in alkaline acetone, concentrated sulphuric acid (purple solutions) and chloroform (yellow solution) but was insoluble in water, aqueous sodium hydroxide, dilute sulphuric acid, acetone, ethanol and other common solvents.

The pigment appeared homogeneous when eluted from columns of magnesium carbonate, silica gel or 'Sephadex LH-20'. Its colour in aqueous alkali and concentrated sulphuric acid suggested that it was a quinone; its ultra-violet and visible absorption spectra (Fig. 1) suggested that it was a hydroxyanthraquinone<sup>3</sup>. Reduction with

Fig. 1. Spectra in chloroform of soil pigment (—) and of 1,8-dihydroxyanthraquinone (---), the latter being almost identical with that of 1,8-dihydroxy-3-methylanthraquinone.

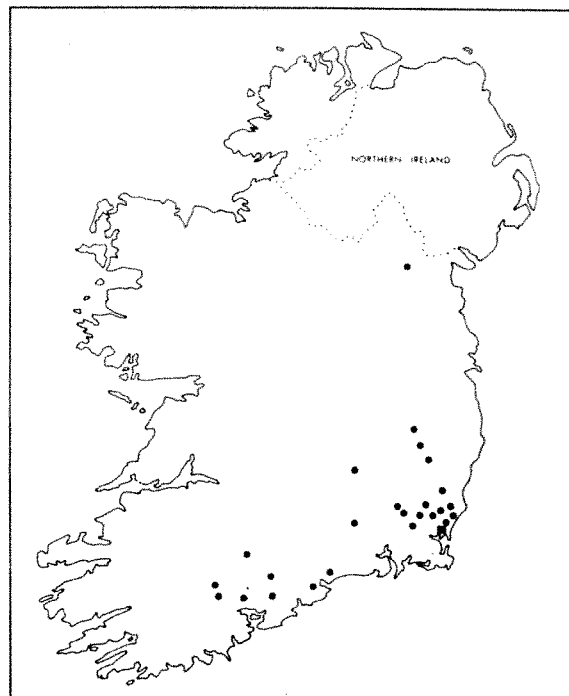

Fig. 2. Location of soils containing pigment. Approximately one in eight or twenty-four in all of the soils from the south-south-east showed pigment compared with one in more than 450 from the rest of the country. ■, Indicates screen.

zinc dust gave material with an ultra-violet spectrum similar to that shown by anthracene. Prolonged treatment in a sealed tube with hot aqueous alkaline dithionite gave, in addition to unchanged starting material, a small amount of pigment with an ultra-violet and visible spectrum identical with that of 1,8-dihydroxy-3-methylanthraquinone. The relationship of the soil pigment to 1,8-dihydroxyanthraquinone was further indicated by the similarity of the infra-red spectra in liquid paraffin of the two pigments especially in the characteristic 1,600–1,700  $\text{cm}^{-1}$  region<sup>4</sup>, both having absorption bands at 1,672 and 1,624  $\text{cm}^{-1}$ . The unknown pigment is not 1,8-dihydroxy-3-methylanthraquinone nor does it seem to be any polyhydroxyanthraquinone reported in the literature<sup>5</sup>.

Many soil samples (678) from all parts of the Republic of Ireland have been examined for pigment. These were available from a previous survey<sup>6</sup> and had been randomly selected with two sites/10  $\text{km}^2$  of the national grid. The top 4 in. of soils under permanent pasture only were taken, bog, forest and mountain areas being excluded. Soils giving a positive test were taken from the locations shown in Fig. 2. With one exception they were all in the south and south-east of the country (Fig. 2). In view of the known root growth stimulating properties of some hydroxyanthraquinones<sup>6</sup> it may be significant that the principal tillage areas are in this region.

I thank Mr J. C. Brogan for supplying samples for analysis and for helpful comments. I also thank Mr R. McCormack for technical assistance and Dr P. Kiely for carrying out X-ray diffraction analysis.

## APPLIED SCIENCE

## Flow of Gases in Porous Solids

ONE of us has recently developed approximate equations for the flow of gases through porous media. The model considers a binary mixture of gases *A* and *B* flowing through a porous medium.

The model is developed for a single capillary by assuming that  $n_A$ , the molar flux through the capillary of component *A* and  $n_B$ , the molar flux of *B*, are each the sum of three terms: a diffusion flux which results from the statistical movement of the molecules under the partial pressure gradient; a viscous flux which results from the general motion of the gas induced by the total pressure gradient; and a net drift flux which arises from momentum transfer requirements within the capillary tube.

The model (though developed independently) is thus similar in form to that recently reported by Wakao, Otani and Smith<sup>1</sup>. The development is, however, somewhat different (particularly with respect to the net drift term) and the method of application to porous media is by using overall constants for the media rather than by considering individual pores.

For the case of flow in a straight capillary, the equations are

$$n_A = A(p_A, p_B) \frac{dp_A}{dZ} + B(p_A, p_B) \frac{dp_B}{dZ} \quad (1)$$

$$n_B = C(p_A, p_B) \frac{dp_A}{dZ} + D(p_A, p_B) \frac{dp_B}{dZ} \quad (2)$$

where  $p_A$  and  $p_B$  are the partial pressures of *A* and *B* respectively,  $Z$  the flow path length and

$$A = - \frac{p_A}{RT} \left[ \frac{\beta}{\mu} + \frac{D_{EA}}{p_A} + \frac{\alpha \bar{V}_A \bar{V}_B - D_{EA} \Gamma_A \bar{V}_B}{\bar{V}_B p_A + \bar{V}_A p_B} \right] \quad (3)$$

$$B = - \frac{p_A}{RT} \left[ \frac{\beta}{\mu} + \frac{\alpha \bar{V}_A \bar{V}_B - D_{EB} \Gamma_B \bar{V}_A}{\bar{V}_B p_A + \bar{V}_A p_B} \right] \quad (4)$$

$$C = - \frac{p_B}{RT} \left[ \frac{\beta}{\mu} + \frac{\alpha \bar{V}_A \bar{V}_B - D_{EA} \Gamma_A \bar{V}_B}{\bar{V}_B p_A + \bar{V}_A p_B} \right] \quad (5)$$

$$D = - \frac{p_B}{RT} \left[ \frac{\beta}{\mu} + \frac{D_{EB}}{p_B} + \frac{\alpha \bar{V}_A \bar{V}_B - D_{EB} \Gamma_B \bar{V}_B}{\bar{V}_B p_A + \bar{V}_A p_B} \right] \quad (6)$$

where  $\mu$  is the gas viscosity,  $\bar{V}_A$  and  $\bar{V}_B$  the mean molecular velocities of gases *A* and *B*,  $\alpha = \pi d/16$  and  $\beta = d^2/32$ , where  $d$  is the diameter of the capillary. It is assumed that the effective diffusion coefficients for the two components are given, respectively, by the Bosanquet<sup>2</sup> interpolation relationship as

$$\frac{1}{D_{EA}} = \frac{1}{D_{AB}} + \frac{1}{D_{KA}} \quad (7)$$

$$\frac{1}{D_{EB}} = \frac{1}{D_{AB}} + \frac{1}{D_{KB}} \quad (8)$$

where  $D_{AB}$  is the binary free gas diffusion coefficient and, for a capillary,  $D_{KA} = 1/3 d \bar{V}_A$  and  $D_{KB} = 1/3 d \bar{V}_B$ . The terms  $\Gamma_A$  and  $\Gamma_B$  are introduced to allow correct calculation of the rate of momentum transfer to the wall arising from the diffusion flux. For pure intermolecular diffusion  $\Gamma = 1$ , and for pure Knudsen diffusion  $\Gamma = 3\pi/16$ . For porous media we can substitute into these equations  $B_0 \equiv \beta$  and  $4/3 K_0 \equiv \alpha$ , and  $m D_{AB} \equiv D_{AB}$ , where  $B_0$  and  $K_0$  are determined in the usual way from permeability measurements;  $m$  is also a constant for the medium. Some difficulty is found in calculating  $D_{KA}$  and  $D_{KB}$  but it seems that, to a first approximation, these could be taken as equal to  $4/3 K_0 \bar{V}_A$  and  $4/3 K_0 \bar{V}_B$ , respectively. This assumption implies that the permeability plot shows no minimum value as is found in the case of straight capillaries. For consistency with

this implication,  $\Gamma$  should be taken as unity for porous media.

It should be noted that there is now considerable experimental evidence for deviation from the straight line form for the permeability plot at low pressure, implying that, even for porous media,  $D_K > 4/3 K_0 \bar{V}$  and as  $p \rightarrow 0$ ,  $\Gamma > 1$ . For simplicity, however, it has been assumed that  $\Gamma = 1$  and  $D_K = 4/3 K_0 \bar{V}$  in the calculation described below.

In cylindrical geometries equations (1) and (2) are readily transposed into cylindrical co-ordinates as

$$n_A = A(p_A, p_B) \frac{dp_A}{dr} + B(p_A, p_B) \frac{dp_B}{dr} \quad (1a)$$

$$n_B = C(p_A, p_B) \frac{dp_A}{dr} + D(p_A, p_B) \frac{dp_B}{dr} \quad (2a)$$

where the fluxes  $n_A$  and  $n_B$  are given by

$$n_A = \frac{N_A}{2\pi r} \quad (9)$$

$$\text{and } n_B = \frac{N_B}{2\pi r} \quad (10)$$

where  $N_A$  and  $N_B$  are the molecular rates of flow of *A* and *B* per unit axial length of cylinder (moles/sec cm) and  $r$  the radius.

In the special case of zero total pressure difference across the porous sample, it is found that the flux ratio is related to the component gases' molecular weights by

$$\frac{n_A}{n_B} = \sqrt{\frac{M_B}{M_A}} \quad (11)$$

Using this relationship and noting that at zero pressure difference the viscous flow component is zero, the following result is obtained

$$N_A = - \frac{D_{EA} P}{RT} \frac{2\pi}{\ln \frac{r_2}{r_1}} \frac{1}{b^2} \left\{ (b-a) \ln \frac{1+bX_{A_2}}{1+bX_{A_1}} + ab(X_{A_2} - X_{A_1}) \right\} \quad (12)$$

where  $b = \sqrt{\frac{M_A}{M_B}} - 1$ , and  $a = \frac{D_{EB}}{D_{EA}} - 1$ ;  $X_{A_2}$  is the mole

fraction of component *A* at radius  $r_2$  and  $X_{A_1}$  the corresponding mole fraction at  $r_1$ ;  $r_1$  and  $r_2$  are the radii of the two surfaces of the hollow cylinder;  $P$  is the total pressure;  $T$  the absolute temperature of the system; and  $R$  the universal gas constant.

Equation (12) has two important special cases.

(1) Under Knudsen flow as  $P \rightarrow 0$   $D_{AB} \rightarrow \infty$  and hence  $D_{EA} \rightarrow D_{KA}$  and the relationship for  $N_A$  becomes, in cylindrical geometries

$$N_A = - \frac{D_{KA} P}{RT} \frac{2\pi}{\ln \frac{r_2}{r_1}} (X_{A_2} - X_{A_1}) \quad (13)$$

(2) Under mutual diffusion as  $D_{KA} \gg m D_{AB}$ ,  $D_{EA} \rightarrow D_{EB} \rightarrow m D_{AB}$  and  $a \rightarrow 0$ , thus

$$N_A = - \frac{m D_{AB} P}{RT} \frac{2\pi}{b \ln \frac{r_2}{r_1}} \left[ \ln \frac{(1+bX_{A_2})}{(1+bX_{A_1})} \right] \quad (14)$$

Preliminary experiments have been carried out at the AERE, Harwell, to verify this treatment using British pile grade graphite as the porous media. The specimens were cylindrical 5 in. outside diameter, 0.75 in. inside diameter and 5 in. long and they were machined from the original block of graphite with their major axis parallel

to the direction of extrusion. The gas flow occurred radially through the tube walls and was therefore perpendicular to the direction of extrusion.

Two gas pairs, nitrogen-helium and argon-helium, were studied in the counter diffusion runs. Measurements were made in the temperature range 20°–600° C at a total mean pressure of approximately 1 atm. with applied differential pressures between –1 and +12 mm of mercury. These applied pressure differences yielded flux ratios between 0.1 and 10.

Single component measurements using argon, helium and nitrogen were made over the same temperature range and at mean pressures ( $\bar{p}$ ) between 0.008 and 0.6 atm. Additional permeability measurements were made with carbon dioxide and methane at room temperature.

At zero total pressure difference the observed flux rates for binary gas diffusion for the two gas pairs were close to the theoretical values (equation 11) of 0.377 for the nitrogen-helium system and 0.317 for the argon-helium system respectively.

Values for  $D_{EA}$  were calculated from equation (12) assuming the Bosanquet relationship applies. The value of  $m$  was obtained by making the appropriate allowance for the Knudsen term. There was no significant variation of  $m$  with temperature or gas pair used and the experimental results indicated a value for  $m$  of  $0.0093 \pm 0.0005$  for the nuclear grade specimen tested. This figure is in good agreement with the figure of 0.009 found from studies of the rate of reaction between pile grade graphite and air<sup>3</sup>. The experimental measurements were repeated with a specially prepared graphite of lower porosity (18 per cent Knudsen flow at atmospheric pressure as compared with the 4 per cent of pile grade graphite). These results yielded a value for  $m$  for this graphite of  $0.0069 \pm 0.0005$ , which was also invariant with temperature.

Using the values of  $m$  found from the zero pressure difference case together with the values of the coefficients  $B_0$  and  $K_0$  measured from permeability determinations, equations (1a) and (2a) were solved numerically to yield estimates of  $N_A$  and  $N_B$  in the presence of an applied pressure gradient. The theoretical predictions and the experimentally observed flows are compared in Fig. 1. In this figure the flows are expressed as "average fluxes" defined as the flow per unit axial length divided by the log

Fig. 1. Variation of gas flux with applied pressure gradient—binary gas flow.  $\Delta$ , Experimental values;  $\circ$ , predicted values.

Fig. 2. Variation of flux ratio with applied pressure difference (nitrogen-helium through nuclear graphite).  $\circ$ , Observed points; —, curve calculated assuming  $m = 0.0087$ ,  $K_0 = 3.25 \times 10^{-6}$  cm,  $B_0 = 5.31 \times 10^{-10}$  cm<sup>2</sup>; ---, curve calculated assuming  $m = 0.0093$ ,  $K_0 = 2.47 \times 10^{-6}$  cm,  $B_0 = 5.10 \times 10^{-10}$  cm<sup>2</sup>.

mean area. The agreement between the two curves in this figure is reasonable. The theoretical curve was obtained using the following numerical values

$$\begin{aligned} m &= 0.0093 \\ K_0 &= 2.47 \times 10^{-6} \text{ cm} \\ B_0 &= 5.10 \times 10^{-10} \text{ cm}^2 \end{aligned}$$

As an alternative approach, inverse calculations were carried out on the actual curve drawn through the experimental points and showed that it was uniquely satisfied by the values

$$\begin{aligned} m &= 0.0087 \\ K_0 &= 3.25 \times 10^{-6} \text{ cm} \\ B_0 &= 5.31 \times 10^{-10} \text{ cm}^2 \end{aligned}$$

These derived figures are within the experimental accuracy of the directly measured values and it is concluded that the theory provides a good approximation to the actual behaviour of the system. The biggest discrepancy is in  $K_0$ , but this parameter has the largest experimental error (it is obtained by extrapolation). Also, the result is relatively insensitive to the choice of the  $K_0$  value for the diffusion is close to normal and the flow close to purely viscous.

When these best values for the parameters are used to calculate the flux ratios at various pressure differences, results as given in Fig. 2 are obtained. The dotted line was obtained using the independently determined values of  $m$ ,  $B_0$  and  $K_0$ . We therefore conclude that the theory provides a reasonable representation of the experimental observations provided that accurate values of  $m$ ,  $B_0$  and  $K_0$  can be determined.

## BOOK REVIEWS

### MASTER AND PUPIL

#### Darwin and Henslow

The Growth of an Idea. Letters 1831-1860 edited by Nora Barlow. Pp. xii+251+8 plates. (London: John Murray, 1967.) 35s. net

THE Reverend Professor John Stevens Henslow, professor first of mineralogy and then of botany at the University of Cambridge and later Rector of Hitcham, was "one chief means of giving [Darwin] a taste for Natural History", as Darwin hastened to state in the first version of the work usually known as *The Voyage of the Beagle*. Henslow was the mentor who furthered and fixed Darwin's true vocation for the natural sciences while Darwin was a Cambridge undergraduate nominally preparing for the ministry. It was also Henslow who recommended Darwin for the position of naturalist on the surveying ship *Beagle* on her voyage around the world and thus set him in the way of discovering evolution. Further, it was Henslow who counselled Darwin as to collecting and observing on that voyage and Henslow who received the collections which were sent back, who advised Darwin as to their condition and who preserved them for subsequent study. After the voyage, and as Darwin became an established scientist in his own right, the relationship between the two men changed, but friendship continued and Henslow was for Darwin "my dear old Master" until his death in 1861, twenty-one years before Darwin's. (Henslow was the elder by thirteen years.)

Those facts have been known in outline to Darwin's many biographers, and the most significant passages in Darwin's letters of 1831-1837 to Henslow were already included in the basic or, one might say, the official *Life and Letters* (1887) by Charles Darwin's son Francis. Only now, however, do we have the full text of all the known letters for that period when Henslow was a dominant factor in Darwin's life, one might almost say *in loco parentis* as concerns influence on the beginning of his career. Now, too, we can follow the less intimate but more equal friendship through Darwin's letters to Henslow from 1838 to 1860, only one previously published in full and few in part. We owe this to the continuing efforts of Darwin's granddaughter, Nora Barlow, who had already produced *Charles Darwin's Diary of the Voyage of H.M.S. Beagle* (1933), *Charles Darwin and the Voyage of the Beagle* (1945), *The Autobiography of Charles Darwin 1809-1882 with Original Omissions Restored* (1958), and *Darwin's Ornithological Notes* (1963). As in those works, Lady Barlow has again been a meticulous editor, contributing an introduction that sets the Darwin-Henslow relationship in the framework of their lives; footnotes identifying other people who are named and clarifying obscure points; a brief bibliography of the most relevant works; six useful appendices and a good index.

Even if this book contained nothing new, it would attract interest and merit thanks for extracting, uniting, and so clarifying source materials on the interaction of the two men involved. The addition of detail in the first part, until 1837, is considerable, and the whole highlights the fact that Henslow was indeed a crucial factor in Darwin's

development, indirectly and contrary to his anticipation or wishes an essential contributor to the origin of *The Origin of Species*.

Although admittedly less important, the later letters cover matters less widely familiar. Still addressed with somewhat reticent affection, Henslow here becomes one of the many colleagues from whom Darwin sought the facts he was building into the fabric of evolutionary theory. There is, for instance, an amusing sequence of letters in which Darwin is trying with evident difficulty to draw out Henslow on the closeness of alliance of species within genera without revealing that those data would bear on Darwin's still unpublished views on the origin of species. Another quite charming sequence of letters reveals that Henslow had organized a sort of posse of young girls who collected botanical specimens, especially seeds, for Darwin. Darwin, anxious to be generous but not profligate, was dubious as to whether he should reward the maidens with 3d or 6d for each packet of seeds. That particular incident was connected with an abortive attempt to determine whether Azorean species also found in the neighbourhood of Hitcham were particularly apt for overseas dispersal.

As with Lady Barlow's previous books, or indeed all that has to do with Darwin, there are innumerable nuggets of news or reminders. As just one more example, it is pointed out that part, at least, of Loren Eiseley's supposed evidence that Darwin plagiarized Edward Blyth is incorrect. Although Lady Barlow is too courteous to say so, Eiseley could have detected the fallacy before he published his claim.

In sum, this is an excellent addition to Darwiniana, and we are again indebted to its compiler and editor.

G. G. SIMPSON

### ALL THE FISH IN BRITAIN

#### British Freshwater Fishes

Factors Affecting their Distribution. By Margaret E. Varley. Pp. 148 (22 plates). (London: Fishing News (Books), Ltd., 1967.) 31s. 6d.

THIS book is one of a series providing a permanent record of annual lectures maintained by a bequest of the late Frank Buckland. Dr Varley gave the three lectures for 1963 in Glasgow, Leeds and Nottingham, and each lecture has been divided into two chapters in the book. It is concerned entirely with the factors affecting the distribution of the British freshwater fishes.

There is a short introduction which serves to inform the reader that the lectures sponsored by the Buckland Foundation are required "to pay all possible attention to the subject of Economic Fish Culture". Dr Varley then observes that the real value of most of our freshwater fishes is recreational. She indicates the number of anglers in the British Isles, and their division into "game" and "coarse" fishermen, although this division is now becoming less distinct. After a short account of the two approaches to angling, the remainder of the introduction gives a résumé of the zoological status of our freshwater fishes, while Table 1 shows their systematic positions.

In the first chapter the origin of the British freshwater fish fauna is discussed. It is noted that the present distribution of animals depends on the range of tolerance of each species and also on its past history. Thus, the relationship of the British Isles to continental Europe before and after the Ice Age is described, and related to the subsequent colonization of our fresh waters by fish. The chapter concludes with an appropriate warning about the dangers of importing species new to our fauna without very careful thought. The author states that carp introduced into South Africa and North America have done a great deal of damage to the native fish fauna because of their habit of stirring up the bottom mud.

The second chapter considers water temperature and oxygen as environmental factors affecting fishes. Here Dr Varley is in her element; she has worked on trout in experimental conditions and investigated the effect of light, crowding, food supply and water chemistry on their growth. The chapter starts by considering temperature tolerance, upper and lower lethal temperatures, and how these can to some extent be modified by the acclimatization temperature. Table 2 lists the upper lethal temperature of various species of fishes, mainly British. The basal metabolism and growth rate of fish within their thermal range are discussed, and it is noted that there is probably an optimum temperature at which they grow fastest. This leads naturally to a consideration of the temperature cycles in our natural waters, and their relationship to the distribution of fish. The amount of oxygen dissolved in the water in relation to temperature and its effect on the fish is discussed in detail. The relationship between the size of egg and the time of spawning is also examined. Dr Varley concludes that from their oxygen requirements and temperature relationships we can grade our fishes between two extreme types, the coldwater stenotherms with high oxygen consumption and the eurytherms with very low oxygen consumption.

It is a natural step from here to consider the distribution of freshwater fishes in relation to topography and this is done in the third chapter. The classification of flowing waters is first discussed, followed by a survey of still waters. Differences in temperature and oxygen content which can be associated with topographical differences between waters are examined, and are related to the species of fish occurring. Thus the distinction between, for example, the fauna of a salmonid and a cyprinid lake is related to the physiology of these fishes.

The fourth chapter considers the effect of the annual climatic cycle on freshwater fishes. Table 10 gives a summary of annual cycles in British fresh waters and Fig. 15 shows the breeding seasons. The spawning periods, size of eggs and breeding requirements of the fish are examined, and thereafter survival, growth and maturity are considered. It is stressed that we know very little about why fish die. It is noted that parasitic infection becomes more likely with increased age, although my opinion is that this is unlikely to account for more than a small percentage of deaths. Finally, the distribution of our fishes is related to their life histories.

One of the important ways in which animals affect each other is through their food supplies, and in the fifth chapter the feeding of the British freshwater fishes is discussed, and their distribution is related to diet, feeding method and possible interspecific competition. Food webs are discussed, and examples quoted. A generalized account of the feeding of many of the species of fish occurring in the British Isles is given, but the author correctly avoids excess detail which could have obscured the picture. Seasonal periodicity of feeding is noted, and the problem of overwintering is considered. It is stressed that a community of fishes with a variety of feeding habits needs an environment with a properly balanced flora and fauna and a variety of ecological niches. The dredging and canalization of rivers, and the "regulation" and fluctuation of the water level of reservoirs tend to impoverish the environment and result in poorer angling.

The final chapter discusses the commercial aspects of freshwater fishes. It is pointed out that, as a nation, we do not seriously exploit our freshwater fishes as human food. The commercial fisheries which exist for salmon, sea trout and eels are mentioned, and the potential seasonal fisheries for perch and pike indicated. Dr Varley considers that the pond rearing of rainbow trout is likely to become an increasing feature in this country. She suggests, however, that the greatest value of our fishes will always be the provision of recreation for anglers. Accordingly she concludes with a brief account of our fish fauna from this point of view.

There are twenty-two excellent plates in the book. Eleven illustrate different types of freshwater habitats, five show stages in the life cycle of the brown trout, two the egg and the alevin of perch, two illustrate food chains, and two show fish in aquaria.

A bibliography lists nine general books on fishes and fresh waters. References quoted in the text are all correctly listed, there being sixty-six in all. These give an excellent coverage of the general literature and of the work carried out in the British Isles on the aspects of the biology of our freshwater fishes considered in this book. A very adequate index is provided.

This book fills a serious gap in the literature of the British freshwater fishes. The book will be of immense value to the fishery scientist, the biologist or the angler, indeed to anyone who is interested in the origin and distribution of our fishes. Dr Varley has combined scientific thoroughness with the ability to make the book interesting and stimulating to all readers. It is to be hoped that this book will encourage further studies on our freshwater fishes, perhaps with more reference to the place of the fish in relation to the other components of the environment than has sometimes been the case in the past.

JAMES C. CHUBB

## PRESENTATION WITHOUT PURPOSE

### *Biologie et Physiologie Cellulaire*

By A. Berkaloﬀ, J. Bourguet, P. Favard et M. Guinnebault. (Collection Méthodes.) Pp. 322. (Paris: Hermann, 1967.) 48 francs.

### *Génétique et Évolution*

By Claudine Petit et Georges Prévost. (Collection Méthodes.) Pp. 392. (Paris: Hermann, 1967.) 60 francs.

THESE books are part of a series which, in British terms, would be used by undergraduates in their early years, occasionally by the bright sixth former. In both cases the text is well ordered and, for the French reader, understandable. The layout and illustrations are concise, clear and attractive. Each book consists of sections contributed by different authors and unfortunately this has produced a variable quality and a lack of unity.

The thing that strikes you about *Biologie et Physiologie Cellulaire* is the commendable way in which the interrelation of structure and function is depicted. The main cell structures are reviewed and in each case its ultrastructure, chemical constitution, physiology and, where appropriate, its origin are described economically and yet with considerable detail. The nucleus is treated in this way and a section on the morphology and physiology of cell division provides a good introduction to a topic not usually so well treated.

The last sections do not fit into this well-ordered system. One on the permeability and irritability of cells is particularly good in the way it considers research techniques in relation to the results obtained; this is an exception to a major criticism of the book. Otherwise there is a rather cursory treatment of techniques. With a subject in which research depends so delicately on valid techniques they need a much more careful scrutiny than the odd paragraph in small print. It is, for example, a fundamental error not to have included some discussion on the problem of artefacts.

*Génétique et Évolution* is really two books stuck together, the first part on genetics being vastly superior to that on evolution. The coverage of genetics is wide and supported by well-balanced accounts of the evidence for the most important findings. It commences with an elementary, but useful, résumé of the major aspects of the subject, such as variation, phenotype and genotype and mutation. The evidence for DNA being responsible for inheritance

is then reviewed and here, as with later sections, there is continual comparison linking microbial genetics with that of higher organisms. After a discussion of the role of DNA in mitosis, a very thorough account of the genetical consequences of the part meiosis plays in the life cycles of organisms leads, through a consideration of simple inheritance, crossing-over, polyploidy and so on, to a detailed account of chromosome structure and mapping.

Essentially inheritance is considered from what one may call the chromosome's point of view, not that of characteristics. This is reflected, for example, in the absence of reference to multiple alleles, polygenic inheritance, pleiotropy and the like.

Finally discussions of the nature of gene action and the genetic code precede two particularly good sections on mutation and the genetic regulation of cell metabolism.

The second part, on evolution, attempts too much in too little space. It lacks depth. There is little reference to the first part and the standard is uneven. A review of population genetics, selection mechanisms, palaeontological studies and human evolution is attempted. Particularly the latter two subjects suffer but such fundamental topics as breeding systems and polymorphism are treated very sketchily and much of the more recent work in ecological genetics is omitted. Also, in contrast with the first part, rarely is the evidence for statements suitably examined.

After reviewing these volumes I am left with contrasting impressions. They are superbly presented and yet I gain from them the realization that science really can be dull. Why, for instance, should the cool, impassive tone of the scientific paper be used in a text book? Is it really necessary—to quote a minor but symptomatic example—to utilize this sort of jargon: following Smith (1929), Brown (1932) devised an experiment before Green (1933)—particularly when no further details of the references are given?

It is true that certain aspects of scientific activity are dull and probably a spartan element in undergraduate training is necessary. It can be argued that interest and enthusiasm are best communicated through personal contact. The realism of the situation is, however, that the latter is becoming less possible in higher education except at the graduate level and that the written word has to be accepted not just as a major means of communicating information but also of attitudes. I wonder, for example, to what extent dull texts have encouraged dull students who became dull school teachers (using dull texts) communicating dull science to lively pupils who, not unreasonably in the circumstances, turned to other subjects.

What is not always realized is that the most gloriously produced book can be dull. Even good quality writing is not sufficient in itself. In fact, the most essential ingredient of a good text book is a real sense of purpose and enquiry that sparks off interest and leaves the student with the realization that it contained something significant enough to be pursued further.

With the exception of some sections of both the books being reviewed it would not seem likely that they will inspire undergraduates. Their concise exposition, however, would make them useful instructional books and, bearing in mind the general standard of the French of English science undergraduates, this is possibly all they would be used for in this country.

P. J. KELLY

## BACTERIOLOGY TEXT REVISED

### Fundamental Principles of Bacteriology

By A. J. Salle. Sixth edition. Pp. 822. (New York: McGraw-Hill Book Company; Maidenhead: McGraw-Hill Publishing Company, Ltd., 1967.) 100s.

SALLE's *Fundamental Principles of Bacteriology* has been an important student text for nearly thirty years and the

current edition continues to provide a broad introduction to bacteria with lesser contributions on yeasts, moulds and viruses. The format of this sixth edition is pleasing and well arranged and the publishers point out the extensive revision which has been achieved since its predecessor's appearance. The revision, understandably, has been uneven and chapters dealing with applied bacteriology and ecology have received little attention. This criticism is, however, partially offset by the inclusion of recent literature citations to which the reader is directed regularly throughout the text. Other chapters, notably on immunity and the immune response, have been re-written and form excellent introductions to their subjects.

Discussion of bacterial morphology, always an attractive feature of this book, has been greatly expanded and is profusely illustrated with carefully selected material. A disappointment here is the poor coverage given to membranes and membranous structures such as mesosomes and chromatophores. Such omission is made the more obvious by the strange inclusion of mitochondria in this chapter. The chapters on yeasts and moulds have remained largely unaltered and tend to be the least satisfactory in the book. The characteristics of *Mucor* and *Aspergillus* continue to be described in great detail—decidedly unnecessary for the beginning student—while mention of other important genera is omitted or curtailed. That mould cell walls are composed, in addition to cellulose and chitin, of "other substances of obscure nature" is unacceptable in a contemporary text.

The author's intention has been to expound the basic principles of bacteriology and provide explanations of the facts where possible. These aims are realized particularly well in his treatment of microscopy, for example, but departures from this objective are rather frequent. Considerable space is devoted to a catalogue of enzymes (*ex I. U. B.*) and to a Bergey style classification of bacteria. A much more critical discussion of factors affecting enzyme activities and of the principles and criteria of bacterial classification would have been desirable inclusions. The failure to introduce numerical taxonomy into the discussion is regrettable and similar criticism can be levelled at other absences such as continuous and synchronous culture. Newcomers to bacteriology should be cautious of the occasional unwarranted generalizations to be found in this book: thus, death is not invariably exponential as implied, nor are nitrogen-fixing nodules found exclusively on the roots of the Leguminosae. Despite these shortcomings, however, Salle remains a very useful and readable account of bacteriology and presents an interesting view of bacteria to new students of this and allied disciplines.

ALAN T. BULL

## CANCER PREVENTION

### The Prevention of Cancer

Edited by Ronald W. Raven and Francis J. C. Roe. Pp. xiv+397. (London: Butterworth and Co. (Publishers), Ltd., 1967.) 120s.

UNDENIABLY, cancer prevention has become an important branch of preventive medicine, and in the future its importance may be expected to increase. Any book on this topic which is edited by senior members of the staff of the Royal Marsden Hospital, London, and the Chester Beatty Research Institute, Institute of Cancer Research, will be expected to be informative and authoritative.

It is therefore disappointing to have to state that this volume, edited by R. W. Raven and F. J. C. Roe, fails to live up to this expectation, although it contains a few good chapters. One of the causes of this failure is the recruitment of too large a team of authors—"fifty eminent authorities" according to both editions of the dust jacket

—to write 376 pages of text. Another reason is a lack of co-ordination of material at the editorial level, with resulting overlap and repetition.

Apart from an introductory chapter entitled "The Principles of Cancer Prevention" and a final section of three chapters dealing with the future, the book is divided into two parts. One part, of eight chapters, deals with some environmental factors: food, cosmetics, pharmaceutical preparations, trauma, irradiation and viruses. The other part, forty-seven chapters long, deals with neoplastic diseases at thirty different sites, and also discusses methods for early diagnosis of some types of tumour, and prophylactic measures such as anti-smoking clinics.

There are particularly good chapters on "Carcinoma of the Cervix—Basic Research" by R. I. K. Elliot, "Cervix Uteri—Screening for Pre-cancerous Lesions" by O. A. N. Husain and "Industrial Aspects of Cancer of the Bladder" by H. G. Parkes. Regrettably other chapters by undoubted experts in their own field suffer from undue compression, and have become relatively uninformative précis of articles that the same authors have already published more fully elsewhere.

Many of the chapters on neoplastic diseases at particular sites throw little light on the subject—cancer prevention—which is supposed to be the theme of the book, for our ignorance of the aetiology of these conditions makes discussion fruitless. It would have been better to have combined such chapters into one, brief at that, making more space available for fuller discussion of those forms of cancer where positive recommendations for prevention can be made.

Other chapters suffer because important issues are raised and inadequately discussed, but the fact that the discussion is inadequate may not be apparent. For instance, Dr Roe states, under the heading "Detailed Consideration of Certain Food Constituents: Caffeine". "The fact that caffeine is mutagenic (Fries and Kihlman, 1948; Andrew, 1959) gives some credence (*sic*) to the possibility that it is also carcinogenic. However, Goldstein and Warren (1962) found no evidence of a correlation between caffeine consumption and cancer of the stomach or colon in a small epidemiological survey." This completes the discussion. The reader might be forgiven if he inferred that this was the only experimental or epidemiological evidence available, and because caffeine is a very widespread item in diet, for it is a constituent of tea, coffee, maté and coca-cola, among other things, and also has medicinal uses, he might be unduly alarmed. The author, surely, might have been expected to have discussed the mass of epidemiological evidence about caffeine-containing beverages that has been accumulating since the surveys published in the 1930s (refs. 1 and 2) and because he is an experimental pathologist it is surprising that animal experiments<sup>3</sup> that failed to show that coffee was carcinogenic have been ignored.

Another irritating feature of some chapters is the failure to give primary sources in the references. For example, Roe, in his chapter on "Food", says, in relation to lead, "Lead has induced kidney tumours in rats (Roe and Lancaster, 1964)", but the work cited<sup>4</sup> is only a review which refers the reader back to the people who did the original work<sup>5-8</sup>. In at least two other chapters by other authors the same experimental work is referred to (a piece of needless repetition) but the references given are those to the original articles.

Considering that much of the material in the book is in fact not about cancer prevention, and that the ancillary information which fills out the rest of it is not exhaustive and can readily be found elsewhere, the price—120s.—is high, especially because there are no illustrations of any sort. In my view the book is either too long if it meant to discuss present knowledge of cancer prevention, or too short and superficial if it is intended to give a general background to environmentally induced neoplastic disease.

For these reasons I cannot see that, in the form in which it has been published, it meets a real need.

## WOOD FROM THE TREES

### Methods of Wood Chemistry

Vol. 1. By B. L. Browning. Pp. xxi + 384. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1967.) 120s.

DR BROWNING describes his book as a compilation of generally employed procedures used in wood chemistry and of less common methods which would otherwise require frequent reference to a scattered periodical literature. It is, however, more than a laboratory manual for the wood chemist and contains much that is of more general interest and could be read with profit by anyone interested in wood technology. The first volume excludes methods dealing specifically with cellulose, non-cellulosic carbohydrates and lignin, these being covered in the second volume. Methods of pulp analysis are included where appropriate.

The book is in three parts; the first is an excellent introduction to the procedures commonly used in wood chemistry and would alone represent a valuable aid to the chemist working in this field. It includes a short, simple account of wood structure and covers the chemical composition of wood, general laboratory methods (drying, evaporation, filtration, extraction, chromatography and spectrophotometry), methods of sampling and the preparation of samples and the determination of water.

The second part deals with wood extractives in the wider sense of those components of the wood cell not present as structural elements in the cell wall. The various classes of extractives including tall oil and the water solubles are dealt with, the emphasis being on the analysis rather than the chemistry of these substances. However, the inclusion of more structural formulae in this section would have added to its usefulness without unduly extending it.

The third part deals with general procedures and special methods, and includes the staining and colour reactions of wood components, analysis of wood preservatives, sorption and swelling, density and specific gravity and a short but excellent chapter on the examination of bark. In the chapter on staining reactions, the benzidine test for differentiating heartwood and sapwood is described but no warning is given of the health hazard associated with benzidine. The section on preservative analysis is very short considering the importance of this subject and is the least satisfactory chapter in the book. While one can understand the author's reluctance to risk dealing at too great a length with this specialized aspect of wood chemistry, the omission of analytical methods for copper is surprising, copper salts being probably the most widely used of all inorganic substances in wood preservative formulations. Although other wet ashing methods are considered, the sulphuric acid-hydrogen peroxide digestion procedure, which is widely accepted in laboratories dealing with wood analysis, is omitted. In the chapter on density, the beta-radiation absorption method, which is especially useful with increment cores and other small samples, is not mentioned.

Most of the methods described are based on American standards but in many cases these are either already

widely accepted in Europe or differences do not invalidate the methods. A useful list of organizations which issue standards relating to wood chemistry is given in the book.

Cellulose, other cell wall polysaccharides and lignin, which together usually make up more than 90 per cent of the dry weight of the wood, are not considered in this book which may be said to deal mainly with the minor components of wood. These minor components are very diverse, however, and Dr Browning, in writing such a book, risked producing a catalogue of largely unrelated facts and procedures. By choosing relevant material rather than attempting complete coverage of the field and by a simple layout and a concise style this danger has been avoided. The result is a very readable book which should quickly establish itself as a standard reference text. N. J. KING

## HETEROCYCLIC COMPOUNDS

**The Structure and Reactions of Heterocyclic Compounds**  
By Michael H. Palmer. Pp. vii + 462. (London: Edward Arnold (Publishers), Ltd., 1967.) 75s. net.

THIS is an excellent book, and a notable addition to the chemical literature. The author has chosen to make "aromatic character" the connecting theme which runs throughout the book, and accordingly small ring systems are omitted. But although it deals only with 5 and 6-membered heterocycles the scope is still wide; it includes systems with up to four hetero-atoms, benzo-analogues and even more complex structures (for example, porphyrins and pteridines) derived from simpler units. The particular merit of this text is, however, its physically oriented approach to heterocyclic chemistry. LCAO methods are utilized in discussing structures and reactivities of heterocyclic systems, and kinetic and spectroscopic data (particularly nuclear magnetic resonance) are used liberally. There is even a chapter on mass spectroscopy fragmentation. Such a rigorous approach to this topic is welcome and long overdue. Nevertheless, the organic chemistry of the subject is not neglected. Readers will observe that little, and in some instances no, attention is paid to the biochemical aspects of the subject. For example, pteridines are discussed without mention of folic acid or butterfly-wing pigments. This attitude can be justified, however, even in terms of space.

The author's initial chapter on nomenclature and aromaticity is appropriate and valuable, and so is the selection of questions collected under chapter headings at the end of the book, but in my opinion his periodic digressions into alkaloid chemistry are somewhat out of context. They contribute nothing to an otherwise self-consistent approach, and might properly have been omitted.

The book is well written and beautifully printed—the reproduction of formulae is particularly clear. This is a "must" for all who work or teach in this field; the more so because it nicely complements existing "orthodox" texts. G. L. BUCHANAN

## WEAK INTERACTIONS

**Weak Interactions and High-Energy Neutrino Physics**

(Proceedings of the International School of Physics "Enrico Fermi", Course 32. Varenna on Lake Como, 15–27th June, 1964.) Pp. xi + 334. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.) 128s.

It is one of the more remarkable features of the Varenna Summer Schools, organized by the Italian Physical Society, that they manage to strike a very desirable balance between the physical and more mathematical

aspects of the subject. This certainly holds for the 1964 course on weak interactions and high-energy neutrino physics, which can be highly recommended to all physicists who want to acquire a thorough background in this field.

Professor Bernardini and Mrs C. S. Wu between them provide general introductions to beta decay and weak interactions from which the more specialized contributions can be tackled. Professors Primakoff and Dalitz contribute important expositions on "theoretical muon physics" and "properties of weak interactions" (with special reference to unitary symmetry) respectively. The experimental side to muon physics, neutrino experiments and strange-particle decays is dealt with by Professors Lederman, Schwartz and Steinberger while T. D. Lee presents a general survey of high energy neutrino reactions.

There are several briefer contributions, among them N. Cabibbo on weak interactions and unitary symmetry. The so-called octet hypothesis is of course also discussed at some length by Dalitz. Since 1964 there has been a rather stormy development initiated by Adler and Weisberger, which establishes connexions between the weak and strong interactions, but of this hardly anything was known when these lectures were given. This to some extent detracts from the usefulness of this volume, which is a great pity. S. ZIENAU

## EQUILIBRIUM STATISTICS

**Statistical Thermodynamics**

An Introduction to its Foundations. By H. J. G. Hayman. Pp. vi + 256 with 14 illustrations. (Amsterdam, London and New York: Elsevier Publishing Company, 1967.) 95s.

THIS book is a carefully reasoned introduction to the basic formalism of equilibrium statistical mechanics. The three main ensembles are extensively discussed and applied to Boltzmann, Fermi-Dirac and Bose-Einstein gases, and the only "many-body" topic being a short account of a classical imperfect gas. In spite of the term "foundations" in the sub-title the treatment in the body of the text is mathematically simple rather than rigorous although the quantum and classical forms of Liouville's theorem, the adiabatic principle and other subjects are discussed in appendices.

The argument is usually clear, although the relation between the model of a single macroscopic system and microcanonical and canonical ensembles of such models is made rather complicated. Each member of the microcanonical ensemble is assumed to be a "polysystem" consisting of a large number of weakly interacting, localized statistical elements. The latter cannot represent either the non-localized molecules of a gas or the strongly interacting ones of a condensed phase and the "polysystem" becomes physically relevant only in the fifth chapter when the elements are identified with macrosystems and the "polysystem" is a canonical ensemble. Essentially, what is treated is a microcanonical "ensemble" of canonical ensembles. The same thermodynamic functions are denoted by capital or small letters according to whether they refer to members of the microcanonical or canonical ensembles.

For an introductory text there is not quite enough emphasis on the way in which the development of the subject has resolved outstanding physical problems. The second chapter treats the quantum theory of vibrational and rotational specific heats of diatomic gases, but although it refers to the classical limiting values there is no derivation of these in the later chapters on classical theory, which contain no discussion of equipartition. There is no quantitative treatment of the specific heat of a Fermi-Dirac gas although this could be obtained without difficulty from the formalism already developed. The paragraph on number fluctuations on pages 152–3 needs justification.

Although the preface implies that the book can be used by students with no previous knowledge of the subject I would not recommend it as a student's first text. Those who already know the essentials of the theory will find the book interesting to read and discuss. G. M. BELL

## ALL ABOUT AEROSOLS

### Aerosol Science

Edited by C. N. Davies. Pp. xviii + 468. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1966.) 115s.; \$10.50.

THE editor of this book, Dr C. N. Davies, of the London School of Hygiene and Tropical Medicine, is to be congratulated on organizing (and also contributing to) this account of a wide range of knowledge which has by now been accumulated about aerosols. As he says in the foreword, some of the more advanced knowledge was rather inaccessible in spite of the importance of the subject; and certainly there have been very few books which could be turned to for an adequately serviceable account, though there is now also a very recent excellent treatise by N. A. Fuchs, one of the contributors to the present work.

The contributors, distinguished researchers from various parts of Europe and the United States, are well known for their work on aerosols in universities, institutes, and other establishments, in connexion with physics (particularly health physics), medicine, engineering, or industry. They have produced quite a lengthy yet concise account of a very great amount of aerosol knowledge, both practical and theoretical. As an up to date account, well supplied with literature references, the book can be recommended as a useful, timely and convenient exposition, which will undoubtedly help in the further growth of this remarkably intricate subject, and will greatly assist many scientists, in both pure and applied fields.

The first chapter, reasonably enough, is on "Generation and Use of Monodisperse Aerosols", and is by N. A. Fuchs and A. G. Sutugin, of Moscow. It is also very satisfactory to find already on pages 1 and 2 a clear reference to the fact that the particle-size distribution in aerosols usually differs appreciably from the normal (Gaussian) distribution and approximates to the lognormal one, which is a consequence of the nature of the particle growth. The curves in Fig. 1 show the slightly different shape relative to the Gaussian form. The generation of monodisperse aerosols is considered: by condensation (adiabatic expansion of a vapour-gas mixture, or in generators of heat-exchanger type or of the mixer type, or as a result of a chemical process); and by dispersion methods (atomization of liquids or suspensions or by dispersion of a powder). Some of the items of knowledge described are of provocative interest, for example: "It has proved impossible to find condensation nuclei for all vapours. Thus mercury vapour is not condensed on the usual nuclei<sup>42</sup>. Some gases, for example NO<sub>2</sub>, promote the condensation of mercury vapour, but all attempts to produce monodisperse aerosols of mercury have failed. The vapour of indigo behaves in a similar manner<sup>43</sup>." In connexion with atomization of liquids, recent techniques for producing series of identical drops are outlined, such as Mason's method using a vibrating hypodermic needle.

The next chapter deals with "Coagulation of Aerosols", by G. Zebel (of Germany), and the basic theory of Smoluchowski (1916, 1918) is further refined. The editor notes in the foreword, however, that doubts have arisen recently about a factor of 2, in calculating the Brownian coagulation (also called "thermal coagulation") of unequal particles. It must be admitted that calculation of the grain-size distribution as a function of time involves many complications, such as the often non-spherical particle shape and unknown surface form, affecting not only the

mathematical analysis but also the assessment of the validity of the conclusions. Coagulation in external force-fields (electrical-, magnetic-, gravitational-, centrifugal-, and sonic fields) is discussed, and the effects of laminar and turbulent flow.

In the third chapter K. T. Whitby and B. Y. H. Liu from Minnesota review the electrical behaviour of aerosols—charging processes, electrical mobility of charged particles, charge decay of clouds, and so on—in connexion with coagulation of charged particles. One of the few electron micrographs in the book illustrates the chain-like aggregates of roughly spherical particles of methylene blue, a highly charged bipolar aerosol. In the fourth chapter J. Bricard and J. Pradel of Paris give a brief but detailed account of the electric charge and radioactivity of atmospheric ions and condensation nuclei.

Photophoresis, that is the motion of particles suspended in a gas when illuminated by a strong enough beam of light, is discussed theoretically by O. Preining of Vienna in the fifth chapter, and the probable importance of this effect on particles at high altitudes in the atmosphere is indicated. The effects, on particle motion, caused by gradients of concentration and temperature in the surrounding atmosphere, are dealt with in the next two chapters by L. Waldmann and K. H. Schmitt of Germany, and by P. Goldsmith and F. G. May from the AERE, Harwell—the first being on basic theories, and the second of the two on the transport in presence of water vapour (removal of radioactive particles from the atmosphere by rain, and with applications to the engineering of gas scrubbers). Here again, there is an extremely intricate problem of defining even approximately the conditions of velocity, temperature and concentration in the region of a particle.

Filtration is discussed in the eighth chapter by R. G. Dorman, largely from the point of view of theories for estimating the collection efficiency of an isolated fibre, effects of diffusion, and the filter resistance and clogging. J. Pich, of Prague, in the ninth chapter, on the other hand, develops extensively also the theories of aerosol filtration in the complementary case of membrane filters having minute pores, using recent results in fluid mechanics.

J. R. Hodgkinson, of Virginia, USA, in the tenth chapter gives a useful exposé of the optical measurement of aerosols from the extinction and scattering of light. The classical theory of Mie in 1908 led for a long time to only limited applications in this field, but the recent fuller calculations have now made this a valuable method of estimating particle sizes and concentrations.

The adhesion of fine solid particles to surfaces or each other, on contact, is reviewed by M. Corn, of Pittsburgh, USA. This feature of the behaviour of aerosols is clearly important in the aggregation or coagulation, and in collecting or filtering processes. The considerable amount of theoretical work based on molecular-force laws and various assumed particle shapes, surface roughness, and so on, is outlined, and a large body of sensitive experimental work is described briefly, covering many different materials, conditions of humidity, and states of motion of the particles. Once more, the theoretical considerations face the difficulties of knowing and defining the conditions at the surface of the contacting bodies.

Finally, the twelfth chapter, by C. N. Davies, reviews present knowledge of deposition from moving aerosols, mainly deposition of the larger particles swept along by a rapid air current, either in an enclosure or tube, or the atmosphere, under laminar flow or turbulent flow. Anyone living in a city, particularly, will appreciate the desirability of understanding the nature of the aerodynamic capture and distribution of particles such as those emitted from chimneys, industrial works, or otherwise.

Probably the main omission in this otherwise excellent book is an adequate discussion of the growth and nature of solid aerosol particles. Very few electron micrographs are

shown (see pages 83, 218, 270, 274) and do not do justice to the by now considerable evidence of this type. The extreme complexity of the conditions near the actual particles, both during their growth and subsequently, makes it all the more desirable to secure all possible definite evidence. Electron microscopy has in many cases shown directly the shapes and sizes and their distributions. Electron diffraction, also, has shown very sensitively the chemical and crystallographic nature of solid aerosols or their surface regions, and in several cases has thereby given valuable indications of the temperatures at the particle surfaces during their growth (see *Disc. Faraday Soc.*, 30, 113; 1960). Such studies have also shown the degree of surface mobility of the atoms or molecules during condensation on the growing aerosol particles and during their aggregation into chains. All such direct evidence promotes appreciably a healthy basis for considering aerosols not just as aerial intangibles or mean distributions of vague unseen units, but as defined particles of known shape and surface form.

H. WILMAN

## LEDA AND THE ASTRONAUTS

### If the Sun Dies

By Oriana Fallaci. Pp. 415. (London: William Collins, Sons and Co., Ltd., 1967.) 45s.

THIS infuriating book is probably the best thing to have been written about the American space programme. The author, an Italian journalist, is shameless in using her Florentine heritage and her femininity as yardsticks to measure the value of Project Apollo. Even more irritating is her pretence of writing what she learns back to her cultured war-scarred father in Florence. On his behalf, ostensibly, she went to Houston, Cape Kennedy and Huntsville to ask why men wanted to go to the Moon when there were neither trees nor Giotto's there. Her achievement has been in getting them to tell her—with revealing eloquence—and in recording her own conversion. The voyages to space, she decides, are right and necessary; they may be the first steps in colonizing the rest of the universe in anticipation of the day when the Sun dies.

The questions that Miss Fallaci tosses at her witnesses border on the absurd and therefore are well worth asking. Her intelligence and persistence drew out some provocative answers. To Walter Schirra, the feeling of weightlessness was "dignified freedom from everything that's dirty, sticky . . . you move well, without sweat, without difficulty, as if the biblical curse 'In the sweat of thy face and in sorrow' no longer exists." John Glenn, the freckled saint who was humbled by a bathroom cabinet, said "Don't think that people like me don't know what Shakespeare said . . . the past serves me as a guide to the future." And Dr Werner von Braun sees the lunar trip as a gymnastic exercise, a warming-up for learning how to get from one planet to another. Along with Mr Schirra, the German rocket scientist should be grateful to the author. Amid many scathing portraits, each comes through as a more complex, sensitive man than we had thought and Dr von Braun should forgive the tasteless associations by which Miss Fallaci links his smelling of lemon soap with some brutal German soldiers she saw during the war. It is the kind of nasty nuance that hovers in one's mind and the author's skill is that she has made it explicit.

The same goes for the sexual tones of the entire venture. It was time that someone spelled it all out. The rockets are obvious enough, but impatience for the docking and the reluctance to return to Earth deserve the full treatment that they get here (from the astronauts' nurse, a spinster and former midwife).

As a lucid and literate explanation of the National Aeronautics and Space Administration's plans for landing an American on the Moon, the book could hardly be

better. Both scientists and laymen will have much to learn from the voluminous details which Miss Fallaci has assembled. She did her homework well, braving the rude manners and tasteless food served in the stifling motels which border the space cities and the astronauts' personality tests in order to listen to long harangues about astrophysics and rocket fuels. She balked only at the last minute from taking a test spin in the centrifuge.

For half its considerable length, the book is spell-binding. Then the new generation of astronauts arrives; they are bald, tired before their time and, with a few exceptions, hardly distinguishable in their conformity. (One answered in astonishment, when asked if he had children: "How could I not have children at my age?") Lamentably, the story ends before the tragedy of last January gave the space race the poignancy and self-doubts that had been conspicuously absent. All in all, this was a book that needed writing; it was a stroke of brilliance that sent a woman to do it. Yeats speculated about Leda and the swan: "Did she out on his knowledge with his power, before the indifferent beak could let her drop?" The answer here seems to be yes and this book ensures that the knowledge is sharable. BRENDA MADDOX

## OBITUARIES

### Professor E. Kowalski

PROFESSOR EDWARD KOWALSKI died suddenly of coronary infarction on April 15, 1967, in Warsaw. His untimely death in the prime of life, and in his most productive period of scientific activity, has left his friends, collaborators and students with a profound sense of loss.

Professor Kowalski was best known as a haematologist and biochemist, but the range of his scientific interests extended to several branches of experimental medicine. He will be remembered especially for his contributions in the field of blood coagulation. His investigations of fibrinolysis demonstrated for the first time the significant role of the products of the degradation of fibrinogen in the various stages of blood clotting and opened up new areas of research in this very important field. His name was also closely associated with work on erythropoiesis, in connexion with his investigations on the biosynthesis of haemoglobin and the hormonal control of erythropoiesis.

At the time of his death he was not only in charge of the department of radiobiology of the Institute of Nuclear Research in Warsaw, but was also engaged in clinical work as consultant to the Institute of Rheumatology, also in Warsaw, where he simultaneously directed several research projects concerned with iron metabolism and with the physiology and biochemistry of blood platelets.

Kowalski's achievements brought him recognition from numerous scientific bodies in various countries. He was a member of editorial boards of leading haematological journals, and a member of the International Committee of Thrombosis Research.

Kowalski was not only a scientist and a clinician, but a man with a profound interest in the arts and humanities, in which he was extremely well versed. His exceptionally pleasant personality, in his day to day contacts with all those who knew him, won him many friends both in Poland and abroad who will greatly miss him.

K. ZAKRZEWSKI

### Sir John Cockcroft

SIR JOHN COCKCROFT, Master of Churchill College, Cambridge, died suddenly on Monday, September 18 (see page 1321). An obituary notice will appear in a later issue.

## University News:

Glasgow

PROFESSOR G. M. WILSON, of the Department of Pharmacology and Therapeutics, University of Sheffield, has been appointed Regius professor of the practice of medicine in succession to Sir Edward Wayne, who retires on September 30.

## Appointments

ERNST R. PARISER has been appointed chief scientist and director of engineering for the marine sciences programme of Aveco Corporation.

## Announcements

THE closing dates for the receipt of applications for travel grants from the Royal Society's parliamentary grant-in-aid have been changed to March 1, June 1 and December 1.

THE British Empire Cancer Campaign for Research and the recently founded College of Pathologists have been given £500,000 to acquire suitable premises in London as a permanent headquarters. The gift was made by Mr Michael Sobell. As well as encouraging the study by pathology of malignant disease, it is hoped that the gift will strengthen and facilitate collaboration between the two bodies. A committee will be appointed within the next few weeks to discuss how a suitable building can be acquired.

THE Lalor Foundation, Wilmington, Delaware, invites applications for its 1968 awards for postdoctorate research in the field of reproductive physiology. The awards are open to all nationalities and preference will be given to younger members of university or college faculty and staff, with an upper age limit of 41 years. The work may be carried on at the applicant's own institution or elsewhere. The awards may be for a few months or up to one year and may range from \$1,300 to \$8,500, depending on the scope and duration of projects approved. Forms of application and further information can be obtained from the Lalor Foundation, 4400 Lancaster Pike, Wilmington, Delaware 19805.

## Meetings

SEVENTEENTH Chemical Engineering Conference, October 16-18, Ontario (Programme Chairman, Dr D. R. Woods, Department of Chemical Engineering, McMaster University, Hamilton, Ontario).

CONTINENTAL Drift emphasizing the History of the South Atlantic Area, October 16-19, Montevideo, Uruguay (Dr J. T. Wilson, Director, Institute of Earth Sciences, University of Toronto, Toronto).

CLEAN Air Conference and Exhibition, October 17-20, Blackpool (National Society for Clean Air, Field House, Brems Buildings, London, EC4).

BATH Conference 1967, October 18-20, Limpley Stoke Hotel, Bath (J. Hoskin Lamble, Bath University of Technology, Upper Borough Walls, Bath, Somerset).

EXPLODING Wire Phenomenon, October 18-20, Boston (W. G. Chace, Air Force Cambridge Research Laboratories, Laurence G. Hanscom Field, Bedford, Massachusetts).

TECHNOLOGIST in the Ceramics Industry, October 20, Stoke-on-Trent (G. H. Stewart, Institute of Ceramics, Shelton House, Stoke Road, Shelton, Stoke-on-Trent).

X-RAY Techniques in Materials Science: Recent Developments, October 26-27, Institution of Electrical Engineers, London (Meetings Officer, Institute of Physics and the Physical Society, 47 Belgrave Square, London, SW1).

GLOBAL Impacts of Applied Microbiology, November 6-11, Addis Ababa (Dr Aklilu Lemma, Faculty of Science, Haile Sellassie I University, PO Box 1176, Addis Ababa, Ethiopia).

ERRATUM. In the article "Calculation of Crystal Packing: A Novel Approach to the Phase Problem" by A. Damiani, E. Giglio, A. M. Liquori and L. Mazzarella (*Nature*, 215, 1161; 1967) the following corrections should be made on p. 1161: line 29 of the left hand column should read "...  $b = 6.186 \dots$ " and line 50 of the right hand column should read "... coefficient of  $3.5 \text{ \AA}^2$ ", and not  $3.5 \text{ \AA}$  (ref. 2). On p. 1162 the volume number in reference 1 should read IV, and not 5; the second author's name in reference 11 should read Kraut and not Krant; and the name of the last author of the article should read L. Mazzarella and not L. Mazzarell.

# CORRESPONDENCE

## Vegetative Propagation

SIR,—We have in English the phrase "vegetative propagate", which is awkward. Every plant part so used and the plant that establishes from it is necessarily a member of a clone—one of its RAMETS. But this word, already established, tends to throw its emphasis on common origin.

If RAM-ET can be so formed from *ramus*, may we have the slightly more irregular PROPET, which is easy to say and to spell, and use it on those occasions where the whole catalogue: bud, bulb, corm, cutting, offset, rhizome, runner, scion, tuber, etc., is to be understood? Does anyone object?

Yours faithfully,

E. R. WALLACE

88 Hills Road,  
Cambridge.

## Head on the Block

SIR,—Whose 'Head on the Block' (*Nature*, 215, 1215; 1967)? You quote the figures of 1,947 and 1,831 for SRC Research Studentships for 1965 and 1966 as if they were significant. The footnote to Table 1 of Appendix III points out that due to the transfer of awards to NERC and SSRC "the figures for 1966 are therefore not comparable with those for 1964 and 1965". The true comparison is mentioned on p. 23 of the Report—4 per cent up in Research Studentships and 12 per cent in Advanced Course Studentships—about 7 per cent overall.

What better evidence that we are alive to the needs of the newer universities and some of the budding polytechnics could there be than the figures in Appendix III, Table 3 (105 research studentships at Sussex) and Appendix IV, Table 3. (Aston, Bath, Bradford, Brunel, City, East Anglia, Essex, Kent, Lancaster, Loughborough, Surrey, Sussex, Warwick and York—with a total value of £1.7 m out of our total of £21 m.)

I am sorry you do not like our 'Co-operative awards in pure science'—we do try. Some of us feel that to arrange for a substantial number of university research students to spend up to 3 months working on their research project in industrial laboratories is far from being an artificial link with industry.

Yours faithfully,

E. R. H. JONES

The Dyson Perrins Laboratory,  
South Parks Road,  
Oxford.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Tuesday, September 26

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP (at 14 Belgrave Square, London, SW1), at 6 p.m.—Dr L. S. Moody: "Polymethylene Oxide".

## Tuesday, September 26—Thursday, September 28

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2)—Conference on "Magnetic Materials and their Applications".

## Wednesday, September 27

SOCIETY FOR ANALYTICAL CHEMISTRY, THIN-LAYER CHROMATOGRAPHY GROUP (in the Lecture Theatre of Ipswich Civic College, Rope Walk, Ipswich), at 2.30 p.m.—Meeting on "Thin-Layer Chromatography Applied to Foods and Related Compounds".

## Thursday, September 28

INSTITUTION OF MECHANICAL ENGINEERS, APPLIED MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "Steels with a High Yield to Tensile Strength Ratio".

## Thursday, September 28—Friday, September 29

EUGENICS SOCIETY (in the Meeting Rooms of the Zoological Society of London, Regent's Park, London, NW1), at 10.15 a.m. on Thursday and 10.30 a.m. on Friday—Symposium on "Genetic and Environmental Influences on Behaviour".

INSTITUTE OF BIOLOGY (at the Royal Geographical Society, Kensington Gore, London, SW7), at 10 a.m. daily—Symposium on "The Problems of Birds as Pests".

## Monday, October 2

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 9.30 a.m.—Colloquium on "Definition, Realization and Use of Time and Frequency".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Mr D. K. S. Bain: "Power-System Model".

INSTITUTION OF MECHANICAL ENGINEERS, STEAM PLANT GROUP (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "The Combination of the Gas Turbine and Industrial Steam Production".

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at Shell Centre Theatre, Shell Centre, London, SE1), at 6.30 p.m.—Scientific Films.

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURERS or ASSISTANT LECTURERS (with research experience in either some aspect of computing science, such as system programming, or in numerical analysis) in the COMPUTING DEPARTMENT—The Secretary of the University Court, The University, Glasgow (September 29).

ASSISTANT LIBRARIAN (Grade I) (with a good honours degree) with the title of Sub-Librarian in the Faculties of Medicine and Veterinary Science—The Registrar, The University, Liverpool, quoting Ref. RV/168/N (September 30).

ASSISTANT LIBRARIAN to supervise ordering and accessioning and for other administrative duties—The Librarian, School of Oriental and African Studies (University of London), London, WC1 (September 30).

EXPERIMENTAL OFFICER (with experience in instrument design or construction involving electronics or optics, and preferably some experience in spectroscopy) in the DEPARTMENT OF CHEMISTRY—The Registrar, The University, Manchester 13, quoting Ref. 144/67/Na (September 30).

RESEARCH ASSISTANT in the DEPARTMENT OF BOTANY to assist in the study by electron microscopy of the correlations between ultra-structural features and physiology in fungi—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (September 30).

LECTURER/ASSISTANT LECTURER (with an honours degree in botany, a research degree in a relevant field, and some teaching experience) in the SCHOOL OF BIOLOGICAL SCIENCES, University of Malaya—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Kuala Lumpur and London, October 6).

SCIENTIFIC or SENIOR SCIENTIFIC OFFICER (with a good honours degree and postgraduate research experience) for comparative studies on the nitrogen, potassium, and phosphate nutrition of vegetable crops—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (October 6).

LECTURER in BIOCHEMISTRY—The Secretary, The University, Dundee, Scotland (October 7).

SENIOR LECTURER in the DEPARTMENT OF PHYSIOLOGY, The Medical School—The Registrar, The University, Nottingham (October 8).

LECTURER and an ASSISTANT LECTURER in COMPUTER SCIENCE—The Secretary, Birkbeck College (University of London), Malet Street, London, WC1 (October 9).

LECTURER (with a good honours degree and/or a higher degree in sociology or a cognate discipline) in SOCIOLOGY in the DEPARTMENT OF EDUCATION—The Registrar, University College of North Wales, Bangor, North Wales (October 9).

LECTURER (preferably with teaching and research interests in physical geography and particularly in the field of climatology) in GEOGRAPHY at the University of Newcastle, New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, October 13).

LECTURER in INORGANIC or ANALYTICAL CHEMISTRY at the University of Natal, Durban—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (South Africa and London, October 15).

LECTURER in PHYSIOLOGY, and a LECTURER in HISTOLOGY (medical or science graduates) at the University of Cape Town—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough

House, Pall Mall, London, SW1; and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (October 15).

DEMONSTRATOR/SENIOR DEMONSTRATOR in the DEPARTMENT OF INORGANIC CHEMISTRY—The Registrar, The University, Newcastle upon Tyne 2 (October 20).

SENIOR LECTURER (with a degree in geology with research experience, preferably to Ph.D. level) in GEOLOGY at the University of Queensland—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (London and Brisbane, October 27).

ASSISTANT EXPERIMENTAL OFFICER or EXPERIMENTAL OFFICER (with H.N.C. or equivalent qualification in chemistry, biochemistry or biology) in the DEPARTMENT OF RADIOBIOCHEMISTRY to assist in a programme of research involving the application of isotopic tracer techniques to biochemical problems—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, Berkshire, quoting Ref. 67/83.

BIOCHEMIST or CHEMIST (honours graduate or Ph.D.) to investigate the chemical composition of normal and osteoporotic human bone—The Director, Medical Research Council, Mineral Metabolism Unit, The General Infirmary, Leeds.

LECTURER (with teaching and research experience in pharmacology and/or related aspects of physiology) in PHARMACOLOGY—The Secretary and Registrar, Bath University of Technology, Claverton Down, Bath, Somerset.

PALYNOLOGIST (with experience in Palaeozoic and early Mesozoic biostratigraphy, preferably of the Southern Hemisphere) for research and applied palynology—The Director, Bernard Price Institute for Palaeontological Research, University of the Witwatersrand, Johannesburg, South Africa.

PHYSICIST (honours graduate or Ph.D. preferably with previous experience in the operation and maintenance of isotope-counting equipment and in the preparation of biological samples) to collaborate in a biological research programme involving the measurement of radioactive isotopes (calcium, iodine, carbon) and the development of techniques for the measurement of calcium absorption and bone turnover in man—The Director, Medical Research Council, Mineral Metabolism Unit, The General Infirmary, Leeds.

PHYSIOLOGICAL PSYCHOLOGIST/ERGONOMIST to work on the essential qualities and performance characteristics of powered artificial hands—The Director, Powered Limbs Research Unit, West Hendon Hospital, Goldsmith Avenue, London, NW9.

POSTDOCTORAL FELLOW in the DEPARTMENT OF CHEMISTRY to work in the field of the kinetics of atomic and free radical reactions in the gas phase, isomerization and exchange reactions of free radicals and fundamental processes in photosensitization—Professor D. J. Le Roy, Department of Chemistry, University of Toronto, Toronto 5, Ontario, Canada.

PROFESSOR and HEAD of the DEPARTMENT OF MICROBIOLOGY—The Dean, Ontario Agricultural College, University of Guelph, Guelph, Ontario, Canada.

SENIOR TECHNICIAN I in the BIOCHEMISTRY SECTION of the GROUP PATHOLOGY DEPARTMENT based at the North Lonsdale Hospital, Barrow-in-Furness—The Group Secretary, Barrow and Furness Hospital Management Committee, 105 Abbey Road, Barrow-in-Furness.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

## Great Britain and Ireland

Philosophical Transactions of the Royal Society of London. Series A: Mathematical and Physical Sciences. No. 1125, Vol. 262 (27 July 1967): Near-Frozen Quasi-One-Dimensional Flow. 1: The Reservoir Problem. 2: De-Excitation Shocks. By P. A. Blythe. Pp. 203-250. (London: The Royal Society, 1967.) 18s.; \$2.70. [277]

Northern Ireland: Ministry of Agriculture. Leaflet No. 27: Fattening Weaned Lambs and Hoggets. Pp. 11. Leaflet No. 53: Feeding Barley Grain and Straw. Pp. 12. (Belfast: Ministry of Agriculture, 1967.) [287]

Medical Research Council Annual Report, April 1966-March 1967. Pp. viii + 366 + 8 plates. (London: H.M. Stationery Office, 1967.) 26s. 6d. net. [287]

The Natural Rubber Producers' Research Association. Twenty-ninth Annual Report. Pp. 43. (London: The Natural Rubber Producers' Research Association, 1967.) [287]

University College of Wales. Report of the Welsh Plant Breeding Station for 1966. Pp. 141. (Plas Gogerddan, Near Aberystwyth: Welsh Plant Breeding Station, 1967.) 10s. [317]

Library Association Pamphlet No. 30: Administration of Children's Libraries. By Peggy Heeks. Pp. 63. (London: The Library Association, 1967.) 16s. (L.A. members 12s.) [317]

The Information Scientist, Vol. 1, No. 1 (July, 1967). Pp. 1-48. Three issues per yearly volume. Annual subscription 30s.; single copies 10s. (London: The Institute of Information Scientists, 1967.) [317]

University of Oxford. Nuffield Committee for the Advancement of Medicine—Annual Report 1966. Pp. 43. (Supplement No. 11 to the University Gazette, Vol. 97, July 1967.) (Oxford: The University, 1967.) 5s. [317]

Construction Industry Research and Information Association (formerly the Civil Engineering Research Association). Report and Accounts for the year ended 31st December 1966. Pp. 24. (London: Construction Industry Research and Information Association, 1967.) [18]

Annual Report of the Long Ashton Agricultural and Horticultural Research Station (The National Fruit and Cider Institute), 1966. Pp. xiii + 288 + 10 plates. (Long Ashton, Bristol: The University, 1967.) 20s. [18]

Bulletin of the British Museum (Natural History). Zoology. Vol. 15, No. 6: The Cirriped Fauna of Tropical West Africa. By H. G. Stubbings. Pp. 227-319 + 1 plate. (London: British Museum (Natural History), 1967.) 40s. [18]

The Scottish Horticultural Research Institute. 13th Annual Report for the year 1966. Pp. 78. (Invergowrie, by Dundee: The Scottish Horticultural Research Institute, 1967.) [28]

Rubber and Plastics Research Association of Great Britain. Auxiliary Substances for Polymeric Materials. Edited by K. B. Piotrovskii and K. Yu. Salnis. Translated by R. J. Moseley. Pp. 148. (Shawbury, Shrewsbury: Rubber and Plastics Research Association of Great Britain, 1967.) 42s. [28]

Proceedings of the Conference on the Technology of the Sea and the Sea-Red held at The Atomic Energy Research Establishment, Harwell, April 5th, 6th and 7th, 1967. Sponsored by the Ministry of Technology. Vol. 3 of 3. Pp. 513-795. (London: United Kingdom Atomic Energy Authority, 1967. Available from H.M. Stationery Office.) 30s. net. [38]

Albrecht. 5 vollständig neu bearbeitete Auflage von Prof. H. U. Sandig, mit Beiträgen von Dr. M. Schädlich. Pp. 65+34 tafeln. (Potsdam, DDR.: Geodätisches Institut Potsdam, 1967.) [78]

## HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one or two copies of NATURE each week is:

*12 MONTHS (52 issues and 4 indexes)				
Great Britain and Eire.....				£14.0.0 each
United States of America.....				(\$44 each
Canada.....				(\$47.80 each
Elsewhere overseas by surface mail.....				£13.15.0 each
(Charge for delivery by air mail on application)				
*Shorter periods <i>pro rata</i> . (Minimum three months.)				

### MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

12 MONTHS (52 issues and 4 indexes)

Number of Copies	G.B. & Eire	U.S.A.	Canada (by air freight)	Elsewhere (surface mail)
3-5	Each £13.10.0	Each \$42	Each \$46.00	Each £13.10.0
6-11	£12.15.0	\$40	\$43.60	£12.15.0
12 or more	£12.0.0	\$38	\$41.70	£12.0.0

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)

### Editorial and Publishing Offices of "NATURE"

MACMILLAN (JOURNALS) LIMITED

4 LITTLE ESSEX STREET, LONDON, W.C.2.

### ECONOMIA

£ 125 complete delivered and installed.

### TEMPUS

£ 155 complete delivered and installed.

# Reliable Economy or Economic Reliability !!

Don't mind which way you say it, the verdict is the same; in laboratories and research establishments throughout the world, the LKB RadiRac is known as a paragon of reliability.

Dependable performance in all atmospheres, even in fume hoods, a tube capacity of 240 tubes, these are only a few of the many features of the LKB ECONOMIA and TEMPUS. Whether operated on a simple pre-set time or on a pre-set volume basis, or for drop counting, rugged dependability coupled with economy, versatility and safety in operation mean that the flexible RadiRac provides all that is needed in a complete system for fraction collection.

Will YOUR fraction collector be working efficiently in 10 years time?

The Bacteriological Dept., of the Karolinska Institute in Stockholm has one, that was purchased in 1956, working today; along with four or five others purchased at the same time, it is working with superb reliability—see what we mean by ECONOMIC RELIABILITY.

Write today for our fully illustrated brochure which gives you all the facts about the LKB RadiRacs ECONOMIA and TEMPUS. They are guaranteed for 3 YEARS too!

Of course if economy in space is your problem ask for the brochure on the LKB UltraRac—it's the smallest.

Semi-displayed £4 16s. per single column inch. Minimum £2, each additional 1/12th of an inch 8s. Full page £132. Half page across £66. Colour (orange) £15 extra. 1s. is charged for the re-direction of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, Strand, London, W.C.2. Telephone: 01-405 4743. Telegrams: Textualist, London, W.C.2.

### APPOINTMENTS VACANT

#### MEDICAL RESEARCH COUNCIL

BIOCHEMIST or CHEMIST, honours graduate or Ph.D. required to investigate the chemical composition of normal and osteoporotic human bone. Experience of density fractionation, use of the Coulter counter, collagen chemistry or bone tissue culture would be an advantage but is not essential. Opportunities are available for graduates to read for higher degrees. Salary within the range £1,050 to £1,340 per annum for a newly-qualified graduate or from £1,470 per annum for a Ph.D.

Applications, with names of two referees, to the Director, Medical Research Council, Mineral Metabolism Unit, The General Infirmary, Leeds. (912)

#### UNIVERSITY OF LEEDS DEPARTMENT OF PHYSIOLOGY

Applications are invited for a post of Research Assistant in the Department of Physiology. The successful candidate will work with Professor G. R. Hervey on a project concerned with food intake and body composition in animals. Applicants should possess a degree or equivalent qualification and have some knowledge of chemical methods. Salary in the range £785 by £50 to £935 a year.

Applications (three copies), stating age, qualifications and experience and naming three referees, should reach the Registrar and Secretary, The University, Leeds, 2 (from whom further particulars may be obtained) not later than October 9, 1967. (947)

#### WELSH NATIONAL SCHOOL OF MEDICINE TENOVUS INSTITUTE FOR CANCER RESEARCH RESEARCH TECHNICIAN

required for cytodiagnosis. Salary scale £766 to £968 according to age and experience, plus £50 supplementary allowance for additional qualifications.

Application forms and further particulars obtainable from the Pathologist, The Group Laboratory, St. David's Hospital, Cardiff. (961)

TECHNICIAN REQUIRED FOR VIROLOGY laboratory at Queen Mary College (University of London), Mile End Road, E.1. Previous experience is essential and the possession of the I.S.T. or City and Guilds Science Laboratory Technician's Certificate, preferably advanced, or an O.N.C. or similar qualification is desirable though not essential. Salary according to age and ability on the scale £653 to £938 per annum plus London Weighting £60 and possible £30 or £80 special qualification award. Five-day week. Four/five weeks annual leave. Pension scheme. —Letters only to Registrar (B/T), stating full details of age, experience and present work. (983)

## CSIRO AUSTRALIA

### MOLECULAR GENETICIST DIVISION OF ANIMAL GENETICS

**GENERAL.** The Division of Animal Genetics of the Commonwealth Scientific and Industrial Research Organization Animal Research Laboratories has its headquarters at North Ryde, New South Wales, where *Drosophila*, mice and poultry are maintained, and field stations located in New South Wales and Queensland carrying sheep, beef and dairy cattle. Research in the Division covers basic research in genetics and the application of genetics to animal production.

**DUTIES.** Recently a section has been started which includes workers in the general field of the translation of genetic information. It is now proposed to include in this section work on RNA virus genetics. The successful candidate will be responsible for developing the work of the sections which come under the heading of RNA virus genetics.

**QUALIFICATIONS.** Applicants should have a Ph.D. degree in Science with experience appropriate to the field of work, or have had postgraduate research experience of equivalent standard and duration supported by satisfactory evidence of research ability.

**SALARY.** Depending upon qualifications and experience, the appointment will be made within the salary ranges of Senior Research Scientist, \$A6,892–\$A7,974 p.a. or Principal Research Scientist, \$A8,242–\$A9,490 p.a. Salary rates for women are \$A428 p.a. less than the corresponding rates for men.

**CONDITIONS.** Fares paid for the appointee and his dependent family. Further details supplied on application.

Applications, quoting reference number 675/199, and stating full name, place, date and year of birth, nationality, marital status, present employment, details of qualifications and experience, together with the names of not more than four persons acquainted with the applicant's academic and professional standing, should reach:

The Chief Scientific Liaison Officer,  
Australian Scientific Liaison Office,  
Africa House, Kingsway, London, W.C.2, by the 20th October, 1967.

(992)

# NATURE

Several posts are offered to young men and women with an interest in the management of the scientific literature and the presentation of news to the scientific profession and to the general public. A background in science is desirable but not essential. Experience in journalism may be an extra advantage.

Apply Editor, *Nature*, Little Essex Street, London W.C.2 (836 6633).

(1000)

#### ANALYTICAL ASSISTANT

required for Analytical/Quality Control Laboratory situated near Tadworth, Surrey. Applicants should hold appropriate G.C.E. at "A" level or O.N.C. (Chemistry). Previous experience in analytical chemistry useful but not essential as training will be given. Excellent working conditions. Social/Sports Club. Staff Canteen. Transport available from Tadworth and Betchworth Station.—Please apply, Assistant Personnel Manager, Vitamins Limited, 23 Upper Mall, London, W.6, quoting reference AA/WOS. (994)

#### CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY (UNIVERSITY OF LONDON)

Applications are invited for a post as Lecturer in Chemistry. The teaching duties associated with the post will lie in the fields of physical and inorganic chemistry, and preference may be given to candidates with research interests in electrochemistry, or in the study of the structure and properties of surface films. Salary scale (including London Allowance) £1,530 to £2,690 per annum.

Further particulars and forms of application (to be returned by October 2, 1967) may be obtained from the Secretary, Chelsea College of Science and Technology, Manresa Road, London, S.W.3. (955)

## British Scientists and Technologists in North America, we're all set to welcome you back.

UNILEVER RESEARCH offers unsurpassed working conditions and facilities to scientists and technologists in Great Britain. The financial rewards are equally favourable.

If you are planning to return to Britain in 1968/69, Unilever want to talk to you. Our representatives will be in North America during November to recruit scientists and technologists—particularly biochemists, microbiologists, chemists, chemical and mechanical engineers, physicists, statisticians, and systems analysts—into permanent appointments in Unilever laboratories. The tour will take one or more of our people to all the main centres of academic research in the United States and Canada.

### Four Laboratories

Unilever is one of the largest manufacturing and marketing companies in the world, operating in more than 50 countries. Our future depends on the continuing development of novel products and processes. And we know that a progressive, vigorous research organisation, manned by the best men in the field, is vital. In Britain alone, Unilever Research has four laboratories employing more than 500 graduates in a total staff of 2,500:—

#### Port Sunlight, Cheshire

Synthesis, physical chemistry, and properties of surfactants and related materials; mechanism of detergency; formulation and evaluation of new and improved soap and detergent products; development of new processes.

#### Colworth House, Bedfordshire

Plant and animal biochemistry and physiology, physico-chemical studies of biological systems, microbiology, natural product studies, toxicology, horticulture, animal husbandry, food preservation, product and process development. Biochemistry and biology of marine animals at the Aberdeen out-station.

#### Welwyn, Hertfordshire

Physics and chemistry of glycerides, phospholipids, and lipopro-

Tissue Culture: Time-lapse photography at Colworth

teins; mechanism of baking processes; rheology, formulation and assessment of fatty and frozen food products; process studies.

#### Isleworth, Middlesex

Chemical, physical, microbiological and biochemical studies of hair, skin and teeth; formulation and assessment of toilet preparations.

At Unilever, salaries are designed to attract and retain top scientists and technologists. Advancement is determined by potential and performance, expressing either scientific or managerial qualities. For those who wish, there are opportunities for transfer into the operating companies.

#### Now Meet the Selectors

Dr. D. W. G. Dicker—Organic and Analytical Chemist, six years at Port Sunlight, now based in London as Research Division Staff Officer.

Mr. D. Raynor—spent five years at Port Sunlight, later joined Colworth House as physicist—now carrying out basic research related to new food processing techniques.

Dr. B. A. Scott—Physical Chemist, eight years with the Company, transferred to Isleworth from Port Sunlight to work in product development, now Divisional Manager, Dental Research.

Dr. D. A. Walker—joined Port Sunlight as Physical Chemist, moved to Welwyn to continue research in frozen products, now Assistant Divisional Manager concerned with development and exploitation of special materials.

#### Applications

Prospective applicants should contact us, giving brief details of qualifications and experience, the nature of their present appointment, and an address for correspondence. We shall then send fuller information on the scope of our research interests and the arrangements for interviews. Wherever possible, we like to refer applications to the Laboratories, prior to the tour, so that our representatives can be briefed on specific vacancies.

In the first instance, please write to: Dr. D. W. G. Dicker, (Ref. A), Research Division, Unilever Limited, Unilever House, London, E.C.4.

LINTAS UR 160-7452-100

# CRYSTAL SYNTHESIS RESEARCHER

MINES BRANCH  
DEPARTMENT OF ENERGY, MINES AND RESOURCES  
OTTAWA, CANADA

The Mineral Sciences Division requires an imaginative scientist to plan and conduct studies into the growth of single crystals of inorganic materials that are found in mineral assemblages and other inorganic material, particularly by hydrothermal techniques. Initial emphasis will be on the growth of sulphide crystals. Subsequent studies will extend to the growth of simple and complex oxides and other chalcogenide single crystals.

Qualifications include graduation at the Doctorate level, or equivalent, in chemistry, mineralogy or geology and several years of related research experience preferably in hydrothermal techniques.

Salary will be commensurate with training and experience and ranges up to \$15,532 per annum.

Further details and application forms are available from the

**BIO-PHYSICAL SCIENCES PROGRAM  
PUBLIC SERVICE COMMISSION OF CANADA  
OTTAWA 4**

Please quote circular number 67-110-10

(998)

## RADIOLOGICAL PROTECTION SERVICE

(Ministry of Health and Medical Research Council)

Clifton Avenue, Belmont, Sutton, Surrey

requires a

## TECHNICIAN

in Fast Neutron Group to assist in experimental work concerned with problems of radiation protection and neutron studies in the field of health physics.

Qualifications required: G.C.E. 'O' level in at least four subjects which should include English Language, Mathematics and another science subject, preferably Physics, plus at least five years laboratory experience.

Salary scale—£829 to £1,056 per annum plus London Allowance.

Applications, with the name and address of two referees, to the Director at the above address. (958)

WOOLWICH POLYTECHNIC  
LONDON, S.E.18

## HEAD OF DEPARTMENT OF MATHEMATICS

Applications are invited for the above post which is now vacant. The college is proposed for designation as one of the new Polytechnics in Inner London in association with the main professional courses of another college. The department provides courses for University of London and C.N.A.A. degrees. Considerable development is taking place in the fields of computing, statistics, and operational research. The college's Computer Centre, which includes digital and analogue computing and systems analysis amongst its activities, is a part of the department. A continuing development of research is planned, particularly in fields allied to the needs of industry and commerce. Applicants should have suitable academic qualifications and preferably should possess industrial experience.

The department is on Grade VI of the scale of salaries for heads of departments in establishments of further education: £3,140 by £80 (4) to £3,460, plus £70 London allowance (under review).

Further particulars and application form (to be returned by October 11, 1967) from Clerk to the Governing Body, Woolwich Polytechnic, Wellington Street, London, S.E.18. (971)

## UNIVERSITY OF QUEENSLAND UNIVERSITY COLLEGE OF TOWNSVILLE

POSITIONS IN BIOLOGICAL SCIENCE  
DEPARTMENT

Applications are invited for a number of positions in the biological science departments in the University College of Townsville. In conjunction with the existing disciplines of Botany and Zoology strong emphasis is being given to Marine Biology and a professorial appointment has been made.

**Senior Lecturer:** Applicants should have a Ph.D. degree and several years' research and postgraduate training. An interest in the physiology of tropical marine organisms would be an advantage but candidates with other interests will be considered.

**Lecturer:** Applicants should have a higher degree and preference will be given to those whose research interests include experimental taxonomy, animal behaviour, terrestrial ecology or some aspect of vertebrate or invertebrate embryology.

**Senior Demonstrator/Demonstrator:** Applicants should have an honours degree in botany or zoology.

Opportunities for research are available with each position.

**Salaries** (at present under review)

Senior Lecturer: \$A6,400 by \$A200 (6) to \$A7,600.

Lecturer: \$A4,800 by \$A200 (7) to \$A6,200.

Senior Demonstrator: \$A3,800 by \$A100 (5) to \$A4,300.

Demonstrator: \$A3,000 by \$A100 (4) to \$A3,400.

A northern allowance of \$A60 is payable in each case.

The College provides superannuation similar to the F.S.S.U. Scheme, Housing Assistance, Study Leave and Travel Grants. Reasonable travel and removal expenses are payable.

Additional information and application forms may be obtained from the Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1.

Applications close in Australia and London on October 23, 1967. (984)

## UNIVERSITY OF AUCKLAND NEW ZEALAND

### SCHOOL OF MEDICINE

Applications are invited from suitably qualified persons for the following positions in the new School of Medicine:

### CHAIR IN ANATOMY

### CHAIR IN PHYSIOLOGY

In conjunction with colleagues in other disciplines the Professors will be responsible for the development of a co-ordinated course in Human Biology, a new Bachelor of Science degree course for medical students commencing in 1968. They will be responsible for organizing clinical and postgraduate studies in their respective subjects.

The Professors will also be expected to advise on academic and technical staff required for their Departments.

Medical salaries are at present under review. Further information about salaries is included in the conditions of appointment, copies of which are obtainable from the Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1.

In the case of new members of staff coming from overseas the practice is to pay salaries from an approved departure date.

Travel and other removal expenses are allowed within specified limits. Upon the completion of five years' satisfactory service, return fares on an approved basis to country of origin may be granted to the person appointed and his dependent family, provided that such fares are not being met from some other source.

Improved conditions are now in force for candidates holding F.S.S.U. policies.

Applications close in New Zealand and London on October 31, 1967. (986)

## THE LONDON HOSPITAL WHITECHAPEL, E.1

### RESEARCH ASSISTANT

required for one year from mid-September to direct a Research Unit working on human colonic physiology in conjunction with surgical staff. Facilities at The London Hospital and St. Mark's Hospital.

Applications, naming two referees, to the House Governor by September 30. (948)

## SHIPBUILDING AT SEA

It must be galling indeed for other shipping lines to see the effortless ease with which the Cunard Steamship Company has persuaded the British Government to part with £24 million to help with the cost of building another transatlantic liner. As even Cunard readily admits, transporting people across the Atlantic in enormous liners is no longer a growth industry. Traffic has shrunk from nearly one million passengers a year immediately after the war to a mere 600,000 in recent years. Most of these have been crossing in the summer months. The Atlantic is not a cheerful place in the winter and the Queen Mary, the last great Cunarder, used sometimes to arrive at Southampton with only 50 passengers on board, waited on hand and foot by the crew of 1,000. This is no way to make money.

This is one reason why the new Cunarder, named with an entirely predictable sense of conservatism "Queen Elizabeth II", will try to recoup Atlantic losses by cruises in warmer climates during the winter. Whether this will be possible is still uncertain, but it certainly took some of the gloss off the launching ceremony on September 20. When ships were ships, they were at once the quickest and the most pleasant way of reaching America. Now, it seems, they must potter about the southern oceans for half the year in order to maintain an outworn tradition in the Atlantic for the other half. It was hard to feel that the launching of the Queen Elizabeth II was anything but an extension of the nostalgic scenes at Southampton the week before when the Queen Mary left for America for the last time.

It is likely to prove an expensive nostalgia. Cunard will be paying off the loan from the British Government at the rate of at least £2 million a year for the first twelve years of the liner's life. This is likely to ensure that the passenger side of Cunard's activities will continue to show a loss, and the unpalatable prospect emerges of the Government being forced to take over from Cunard the most expensive pleasure steamer in the world. The truth is that passenger ships are a glut on the market. Cunard was fortunate to be able to sell the Queen Mary to the city of Long Beach, California, for £1,230,000—well above the market price. Union Castle recently sold the Capetown Castle, a ship several years younger than the Queen Mary, for a sum it refuses to reveal—it may well have been no more than £100,000. Cunard hopes that in future its profitability will be ensured by its heavy investment in the container cargo market, but the benefits of this will take time to be felt.

What effects will all this have on shipbuilding? The launching of the Queen Mary in the thirties was a signal for new optimism in the industry; the Queen

Elizabeth II, unfortunately, is more widely interpreted as a sign of hardships to come. Shipbuilding in Britain is going through yet another crisis. At the end of June, only 1.9 million gross tons of shipping were on order in British yards, representing barely 18 months work—less in some areas. There has been a modicum of jubilation now that the Esso Petroleum group has placed orders for four giant tankers of 240,000 tons with Swan Hunter on the Tyne and Harland and Wolff in Belfast, but these will not keep the wolf from the door indefinitely. In the long run, the shipbuilders need encouragement in the form of a reduction in the price of steel plate. The cost of steel is an important item, making up between 20 and 25 per cent of the total cost of a ship. It is no wonder that the shipbuilders, as a way of forcing prices down, are threatening to buy British steel on the Swedish market, where it sells for £35 a ton—much less than the home price of £42 a ton.

Clearly this is no more than a ploy to make Lord Melchett, Chairman of the British Steel Corporation, think hard about his determination not to cut prices for a single industry, but there is a precedent for it. Until 1949, all shipbuilding steel in Britain was sold at a discount—in 1931 the discount was 22.5 per cent, but by 1939 it had fallen to 6.5 per cent. After the war, shipbuilders with full order books had no need of the subsidy, and it came to an end. But the Geddes Committee on the shipbuilding industry, which reported 18 months ago, suggested that the price differential should be reinstated as a matter of urgency. The committee said that the costs of steel to the shipbuilders should be reduced by 10 per cent, leading to a 2 per cent reduction in the cost of building merchant ships. On a very large tanker of 200,000 tons, this would produce a cost reduction of about £120,000, and bring British costs more nearly into line with Continental and Japanese yards.

There are, however, some solid arguments against the idea. Steel company profits have themselves been under strong pressure, and a subsidy to shipbuilders, the companies say, would force up the price of steel to other users. Should car manufacturers, or manufacturers of structural steel or pressure vessels, be handicapped for the sake of the shipbuilders? On economic grounds, the answer must be no. While the shipbuilding industry cannot be ignored, it is nevertheless surprisingly small. From the 27 yards covered by the Geddes inquiry, sales in 1963 amounted to £159 million. In the same year, the turnover of the British Motor Corporation was £444 million and the Distillers Company £303 million. Even taken as a whole, the shipbuilding industry is comparatively small. It is also diffuse, a consideration which led the

Geddes Committee to recommend amalgamations on a wide scale. In fact, these mergers have been happening, first on the Tyne, and more recently on the Clyde, but mergers are no substitute for orders. The trend towards larger and larger ships is also acting against the multiplicity of shipyards in Britain—for each ton produced, the average amount of shipyard work has fallen.

Given the need for rationalization—which is admitted inside as well as outside the industry—it is hard to argue in favour of measures designed to enable the industry to stagger on in its present form. Things may well get worse before they get better, but to relax the pressure on shipbuilding now would be to lose the benefits of rationalization later. One way out would be an overall reduction in steel prices but, although this will probably be one of Lord Melchett's first objectives, it would be imprudent to count on anything substantial. There is another argument the Government would be wise to ignore. As it happens, shipbuilding is concentrated where unemployment is already high—the north-east, Belfast and the Clyde. The Ministry of Power seems to have been persuaded to abandon its cheap fuel policy in the interests of keeping miners employed, and there is a danger that pressure will be brought to bear on the BSC to abandon its policy of uniform prices to do the same for the shipyards. It is a pressure that should be resisted.

## ANTI-WHO MISSILES

ALTHOUGH the announcement on September 19 from Washington that the United States is to deploy a "thin" defence against ballistic missiles has caused a great stir, there is still no means of knowing just why the decision has been made at just this time. It is true that the pressures in favour of anti-ballistic missiles have been apparent for months or even years, but the US Secretary of Defense, Mr Robert McNamara, should long since have grown used to them. There is nothing in the history of the past few months to suggest that he has now surrendered to what is, after all, only a small and familiar part of the public opinion with which he has to live.

So is it the case, as Mr McNamara said, that the immediate provocation is the likelihood that mainland China will be equipped with inter-continental missiles by the early seventies? And is that a sufficient argument? Mr McNamara is of course in a position to know better than most people outside China just what the Chinese are about, but it is hard to think that the Chinese will have anything like an effective long-range missile system before 1975 or thereabouts. After all, a few missiles do not make a striking force but only, sometimes, a provocation. So is it possible that the Department of Defense has its eyes on the Soviet Union instead, and that the continuing deployment of anti-ballistic missiles there has tipped the balance of the argument in favour of a

similar policy in the United States? Here again, there is something in the argument but not enough to make a convincing case. In his announcement on September 19, Mr McNamara went out of his way to claim a "three to one" superiority in long-range missiles, which implies that the Russian anti-missile defences, whatever they are, cannot decisively alter the strategic balance. In other words, if the United States has waited this long before building an anti-missile system for itself, it is hard to see why it could not have waited yet another year.

Even within the United States there are powerful arguments in favour of delay. For one thing, there is always the possibility that the system soon to be installed will turn out to be a much less durable investment than some of its supporters expect. The plan is that there shall be two separate kinds of anti-missile missiles—one called Spartan with long range which is intended to make interceptions at a considerable height above the Earth, and another called Sprint designed for rapid acceleration towards hostile missiles nearing their targets. The awkward facts of missile defence by themselves compel some kind of dependence on a mixed system like this. Long-range interception is preferable for all kinds of reasons, only some of them economic, but it is also necessarily a chancy business, at least in the present state of rocket technology. It follows that there must also be some kind of point defence of the kind that Sprint is intended to provide. The snag, from the point of view of American taxpayers anxious to know what they will get for \$5,000 million spent on anti-missile rockets, is the likelihood that the system now to be installed will soon be superseded by more effective systems. Much simpler radar systems than those around which the new defences will be built are notoriously prone to all kinds of uncertainties when first introduced to active service. From a strictly technical point of view, delay should save money and bring greater effectiveness, although performance is bound always to fall a long way short of perfection.

These, however, are parochial arguments. The decision to build an anti-missile system in the United States is more worrying because of what its consequences will be elsewhere. The simple argument that this is yet another twist in the costly spiral which has led to the development of increasingly sophisticated and dangerous weapons since the Second World War is probably, as it stands, too simple by half. For one thing, the resources that the United States and the Soviet Union will devote to these activities are probably only small fractions of what they spend already on defence. (They are also unlikely at this stage to undertake to build fallout shelters on the scale which logic demands should accompany anti-missile systems, more or less on the principle that a defensive weapon which kills its own people is no defence at all.) It is also probable that, in the years immediately ahead, anti-missile rockets will occupy a comparatively undignified place in the military budgets of both countries. There will be a

temptation to spend enough to stay in the business without taking resources away from more urgent projects. Moreover, there is no prospect in the measurable future that countries other than the United States and the Soviet Union will be tempted to follow suit. Yet, even if there is no arms race in the classical meaning of the term, it is an important setback that the two credible nuclear powers have now abandoned their tacit agreement that plausible mutual deterrence is some kind of assurance of stability. The American Government has creditably taken the initiative, in the past few months, in trying to negotiate an agreement not to deploy anti-missile rockets, and the report that it has been rebuffed is not by itself a proof that the time has come to abandon the attempt. A few months more might have made a difference.

Where relations with other nations are in question, the timing of this development is particularly unfortunate. It is tactless, to say the best of it, for the two nuclear powers to have embarked on the development of another generation of nuclear weapons at a time when they are both apparently doing everything they can to win the agreement of lesser fry to the non-proliferation treaty being negotiated at Geneva. Will this help the Indians or the Italians to sign away their rights, however theoretical, to manufacture nuclear weapons for themselves? The decision in the United States is likely to have more particular consequences in Europe, where anti-missile systems are likely indefinitely to remain too expensive and unworkable. One result will be that the French will be confirmed in their official view that the United States cannot be trusted with the defence of Europe. Those nations in Western Europe who consider that the North Atlantic Treaty Organization has a useful job to do will find it necessary to whistle harder to keep the spirits up. This is a lot to lose for such a little gain. Yet nowhere in Mr McNamara's statement is there any sign of a move to help create in mainland China—by discussion, although public speeches can do a lot of good—the kind of awareness of the damage which nuclear weapons can do which is, in the long run, the only assurance that nuclear powers will make a rational appraisal of their responsibilities. One way and another, this is a lot to lose for such a little gain.

## ANOTHER CROCK OF GOLD?

THE new academic year seems to be starting quietly enough in Britain, and this may be just as well for all those with responsibilities for the smooth running of the forty-four universities now in business. There is, after all, plenty of hard work to be done. The anxieties of the late summer, when some people proclaimed that they would not have all the equipment necessary to operate laboratories efficiently, seem not to have materialized in their full rigour. And it will be some

weeks before it is known just what kind of settlement the University Grants Committee has reached with the Department of Education and Science on the financing of the next quinquennium which begins a year from now. In the circumstances it is tempting to forget that the year ahead is likely to be critical for British universities. In the circumstances, it is a public service that Professor Max Beloff has been sounding off (*Minerva*, 5, 520; 1967) about the relationship between British universities and the public purse. He will at least succeed in reminding several people of the battles that lie almost immediately ahead.

Professor Beloff has also raised the unfashionable cry of academic freedom. He is principally concerned with the intrusion of public administration into the running of the universities. To him, the prospect that the accounts of the universities shall be open to inspection by a civil servant—now chosen to be the permanent secretary at the Department of Education and Science—is a red herring. The real threat is the way in which the University Grants Committee and the research councils are able, independently or in concert, to influence the way in which universities conduct their business. Innovation is usually dependent on the public purse—that is how the argument goes. The result is that autonomy has almost disappeared. But since it is unthinkable that the one who has paid the piper will refrain indefinitely from calling the tune, the universities must win back their independence by finding some substantial source of private funds. By this test, as Professor Beloff is quick to point out, it was mistaken of the Franks Commission to recommend a further centralization of the University of Oxford. Robbing the colleges of their independence will only put the university as a whole in pawn.

Nobody will deny the daring of this sally, for ever since the Franks Commission eighteen months ago, Oxford has been lying low for fear of attracting too much attention. And there is, of course, a great deal in what Professor Beloff has to say. The universities have been through a bad spell. The UGC has by its tactlessness provided half a dozen reminders of who is master now. The Secretary of State for Education and Science provided a nasty slap in the face in December 1966 by deciding without consulting the universities that students from overseas should pay bigger fees. At the same time it has become all too obvious that the universities are badly equipped to defend themselves. It will be a long time before the universities can answer back persuasively. It is, however, wrong and dangerous to think it possible to build a shield against intrusion by collecting private funds. In simple money terms, it is unlikely that anything less than £20 million a year—say, 10 per cent of university expenditure—would suffice to keep the universities independent. But where is such a fortune to come from in a country which is hard pressed to raise much smaller sums for equally deserving causes? And how could private endowments safeguard the independence of the universities as a whole, not just that of the best favoured? These questions answer

themselves. In the long run it would be a great advantage if British universities had more money to call their own (and they could do a lot to help themselves by playing on the affections of their alumni), but there is no realistic prospect that the universities will be able to buy their way out of trouble.

In any case, the weakness of the universities is partly their own creation. They are too vulnerable to sharp questioning about cost-effectiveness. Although some of the newer universities have taken it on themselves to carry out deliberate studies of the most efficient ways of teaching, many institutions are unreasonably sensitive to suggestions that different ways might bring greater benefits. Ironically enough, teachers as well as students often suffer from the same mismanagement. In Oxford, for example, the Franks Report—as much a defence of the present arrangements for undergraduate education as a proposal for reform—showed quite clearly how strictly administrative changes could bring great benefits in the working of the university. Sir Hans Krebs, in his article in this issue (see page 1441), shows how the same muddles impede the conduct of research at Oxford. So is it surprising that the custodians of the public purse should have become uncomfortably suspicious of the way the universities conduct their business? And because there is no prospect that British universities will ever be entirely free from dependence on public funds, is it realistic of them to seek autonomy without first taking scrupulous care to see that their own operations are above criticism of all kinds? In the long run, the universities will only be able to defend themselves against intrusion when they are better able than their would-be critics to decide what part universities should play in modern society and then to decide how best to attain desirable objectives. This means in practice that the universities must organize themselves for change. Somehow they must design a means by which they can arrive, by common consent, at workable decisions.

Strengthening the Committee of Vice-Chancellors is an obvious step to take, but means will also have to be found to give the people who work in universities a better sense of being represented and a clearer conviction that they must be bound by collective decisions. Inevitably, universities will have to become more attentive to problems of cost-effectiveness. They need to be so enterprising in this respect that they can forestall the criticisms of those outside. When they have done everything that can be done in ways like these, it will be time enough to pass the hat around.

## TOO MUCH IRON?

FOR several decades it has been plain that there are serious problems to be solved before the abundance of iron in the parts of the universe accessible to observation can be properly accounted for. The most conspicuous difficulty to be overcome is that iron seems

to be relatively much less abundant in the atmosphere of the Sun than in the solid objects of the Solar System—the metallic parts of the chondrites which reach the Earth as meteorites and the Earth itself. The article by P. G. Harris and D. C. Tozer on page 1449 of this issue is an ingenious attempt to account for what seems to be a segregation of iron into the substance of the inner planets. It is, of course, improbable that doubts will now be resolved—the authors would probably be the first to admit as much. But there is at least a chance that interest will be re-awakened in this awkward problem, which can only be a benefit.

The first thing to be said is that the problem of iron in the Solar System is almost the personal creation of Professor Harold Urey, who with his collaborators over several decades has compiled the evidence which shows the disconcerting variation of the abundance of iron from one object to another. The ratio of iron to silicon in the atmosphere of the Sun is less than a third of that in the chondrites, and only a fifth of the ratio of iron to silicon which must be assumed if the Earth has a molten core of iron and nickel of much the same composition as the metallic parts of meteorites. It is true that the relative abundance of iron on the Earth is comparable with that in the carbonaceous chondrites, which by this test are the most likely representatives of primeval matter, but this coincidence only makes it more necessary to explain why the Sun appears to be deficient in iron. Are the measurements in error? Or was there some process of fractionation during the formation of the Solar System which concentrated segregated iron in the inner planets?

Harris and Tozer have suggested a mechanism of the second kind. They suggest that iron may have accumulated preferentially in the inner planets as a result of magnetic attractions between particles of iron dust in the material left over after the formation of the Sun. The point is that particles of iron held magnetically together are less likely than other kinds of dust to be swept away by the outward radiation pressure of the Sun. One difficulty, of course, is that it will only be possible to test this argument when much more is known about the details of the formation of the planets and about the mechanisms by means of which their composition has been altered in the past five thousand million years or so. Another is that of accepting such a comparatively simple explanation for what has seemed, in recent years, to be an extremely complicated problem. In the long run it is probable that room will have to be found in any comprehensive theory for at least some of the explanations which Urey has devised to explain, for example, how some kinds of meteorites may have lost some kinds of elements preferentially. Indeed, the complications of these arguments have at least the virtue that they bring together several different kinds of observations—the compositions of meteorites, the geophysics of the planets and the theoretical calculations of the natural abundances of the elements, for example. But none of this implies that there is no room for new ideas. Here, as elsewhere, every innovation helps.

## NEWS AND VIEWS

### Engineers in Profile

As part of their efforts to stimulate engineering, and to encourage more children to become engineers, the Ministry of Technology and the Council of Engineering Institutions decided some time ago that it would be useful to know exactly what an engineer is. The result of their investigation, a booklet entitled *The Survey of Professional Engineers 1966*, was published this week. The ministry claims that it is the most comprehensive study yet made of a profession in Britain; questionnaires were sent to no fewer than 25,000 engineers, of whom 86 per cent replied.

The typical engineer, it seems, is young (two-thirds of the sample were under 45) and works in industry. More than half of the sample work in private industry, while nationalized industries took another 14.2 per cent. Universities and colleges of technology employed only 455 engineers, 2.4 per cent of the sample. The study also provides some useful information about engineers' salaries. The median salary for 30 year old engineers, for instance, is about £1,500 a year, and by the age of 40 has climbed to £2,100. Those in the upper decile earn £2,000 a year at 30, but have gone up sharply to £3,300 by the age of 40. The top salary recorded was £17,400, and 10 per cent of the whole sample earned at least £3,500.

There does seem to be an advantage in being a graduate in engineering; 55 per cent of graduate engineers earned more than £2,000, while just over 40 per cent of non-graduate engineers did so. Graduates are twice as likely to earn £3,000 as non-graduates. Of different categories of engineers, chemical engineers are still the best paid, although other branches have narrowed the gap since 1959. Over the period of six years, electrical engineers have improved their incomes by 7.2 per cent per year, while chemical engineers have increased by only 3.9 per cent per year. Chemical engineers still manage to earn more, however, for which their large graduate entry must take some of the credit; the median salary for chemical engineers is £2,729, while that for mechanical engineers is £2,249, electrical engineers £2,404 and civil engineers £2,268.

The engineers returning the questionnaire were also asked to make a judgment of their levels of responsibility. Despite the human tendency to exaggerate, which is likely to exaggerate the degree to which engineers shoulder industry's burdens, only 11.4 per cent of the sample considered themselves top management. A further 22.3 thought they were middle management, and 25.8 favoured junior management. The rest, 40.4 per cent, described themselves as performing technical and engineering functions.

### No Coals to Newcastle

CONFUSION increases about the policy of the British Government towards fuel in general and coal in particular. The policy of cheap—or at least moderately cheap—fuel put forward by the Minister of Power, Mr Richard Marsh, as recently as July has for practical

purposes been abandoned by the Prime Minister's decision that there should be a halt to the closing of collieries. But for how long will the Government be able to resist economic pressures on the British coal industry which have their parallels in most other countries in Europe? For a month, perhaps, until the Ministry of Power has time to produce its new White Paper on fuel policy—by which time the annual conferences of the Labour Party and the National Union of Mineworkers will conveniently be over? Or until the spring of 1968, when miners thrown out of work would be less conspicuous? Or will there be a more or less permanent postponement of the full rigours of cheap fuel?

Uncertainty about the Government's intention has now been given an awkward twist by Mr Dan Smith, a government stalwart in Newcastle upon Tyne, and chairman of the North-east Regional Development Council, who says that he will resign if the National Coal Board closes down one large colliery in his district. This is not so much an attempt to give the policies of the National Coal Board a parochial flavour as a protest against the way in which a public body appointed only two years ago to guide planning and development in the North-east has been made to feel that it is but a piece of window-dressing. (The chairman of the corresponding council for the north-west of England, Dr C. L. Carter, disclosed a similar sense of grievance only a week or so ago.) Mr Smith's protest has been given some extra piquancy by conflicting reports about the Coal Board's intentions towards the colliery in question, but it is hard to think that all those now in dispute with one another will be able to keep both their dignity and their jobs.

Altogether, 19 collieries would have been closed in the ordinary course of events before the end of 1967 and six are likely to shut in any case because reserves are worked out. Precisely what it will cost to keep the others going is hard to calculate, partly because exact figures are not available and partly because there are no simple standards of comparison. On the assumption that the National Coal Board counts the most costly pits among its potential closures, however, the total cost of the unwanted coal produced in the coming winter will be measured in tens of millions of pounds. Moreover, it is plain that the British mining industry has a long way to go before it has dispensed with its long uneconomic tail. The cost of producing heat energy from British collieries ranges from less than 3d. a therm (=10<sup>6</sup> British thermal units) to more than twice as much, as shown in the following table.

Cost (pence per therm)	Production (millions of tons)
Less than 3	10.4
3-4	50.8
4-5	59.7
5-6	27.3
More than 6	9.5

In a world in which the Ministry of Power has vowed not to agree to a price for North Sea gas anything like 5d. a therm—the price agreed two years ago for the first supplies from the well sunk by British Petroleum—even the target of an annual production of 155 million tons of coal by the end of the sixties may well, by then, seem an inexplicable extravagance.

## Message from Kapitza

PHYSICISTS in Britain and particularly in Cambridge have been heartened by the following telegram of sympathy about the death of Sir John Cockcroft sent last week by Dr Peter Kapitza:

Dear Vice-Master,

Please convey to the fellows and members of Churchill College my deep sympathy and condolences at the sad event of the death of your master. I am deeply shocked by the news of the death of my friend Sir John Cockcroft, as we knew each other for more than 40 years. He was a physicist of great insight, masterly technological gifts and a brilliant organizer. With his quiet and charming ways Sir John was a stubborn fighter for progressive views not only in science but also in international affairs. We know Sir John as a promoter of peace and international collaboration. It was my privilege together with Sir John to bring closer the scientists of our two countries. I sincerely hope that this fine tradition will be followed by Churchill College. Churchill College was the last great achievement to which Sir John brought so much of his personality, thought and touching love and where he and Lady Cockcroft with such tact lived up to their high position as first dwellers in the Master's Lodge of Churchill College.

Yours very sincerely, PETER KAPITZA

Dr Kenneth McQuillen, Vice-Master of the College, replied the same day in the following terms:

We are deeply touched by your stirring message of sympathy on the tragic death of our master, Sir John Cockcroft. It will help us to follow the tradition of bringing closer the scientists of our two countries which he and you have done so much to establish and which was so close to his heart.

This friendly exchange is much valued not merely as a mark of the respect in which Sir John Cockcroft was held but also because it has helped to take some of the sting out of the sudden departure of Dr V. Kachenko from London. It is known that Dr Kapitza took a personal interest in Dr Kachenko's stay in Britain. It is therefore hoped that his telegram may fairly be taken as a sign that scientists in the Soviet Union will not be alienated from the programme of scientific exchanges by the mismanagement of Dr Kachenko's departure.

## Successor for Kerr

THE eight months search for a new president for the University of California ended last week with the appointment of Mr Charles Hitch as a successor to Dr Clark Kerr. Mr Hitch is at present with the Rand Corporation, but his reputation since the war stems from his work with the Department of Defense and the Bureau of the Budget, where he has had an important influence in the development of techniques for the introduction of cost-effectiveness criteria into military and economic planning. Given that Dr Kerr's departure from the presidency took place at a time when the Governor of California, Mr Ronald Reagan, was pressing for a reduction of the cost of running the university, it is ironical and possibly significant as well that Mr Hitch has in the past few years been paying

close attention to the cost-effectiveness of running universities.

Mr Hitch has an outstanding reputation as an administrator, although his career began before the Second World War in academic life. He was a Rhodes Scholar in the early thirties and taught economics at Oxford until the outbreak of the war. After military service he returned to the United States and the Rand Corporation. His spell in Washington began in 1961, when he was appointed Comptroller at the Department of Defense. His work with the Bureau of the Budget began in 1964. He returned to the Rand Corporation a year ago.

It remains to be seen how the appointment of Mr Hitch to the presidency will affect relations between the Governor of California and his university. Since the departure of Dr Kerr, the Board of Regents seems to have reasserted some at least of its traditional independence; theoretically it should function in relations between the university and the state much as the University Grants Committee used to function in the public dealings of British universities. One sign of this is that the Board of Regents is planning to submit a budget for the academic year beginning in 1968 which represents an increase of roughly 25 per cent on what it has had to spend this year. In part, of course, the size of this increase reflects the way in which the budget for 1967 was reduced immediately after Mr Reagan came to power, but obviously it includes a considerable element of growth as well. But it is unlikely that Mr Hitch will be able to pare down the budget intelligently, which implies that he will find himself defending a budget which is larger than the governor can welcome. The University of California may find that Mr Hitch must show his mettle before the year is out.

## Money for Students

A SCHEME for helping American students to pay for higher education has been devised by a committee of the Science Advisory Committee in Washington under Professor J. R. Zacharias of the Massachusetts Institute of Technology. In a report now published, the committee urges that there should be established what is called an "educational opportunity bank" which would be able to lend money to a student in return for an agreement to pay back a percentage of his income for the thirty or forty years he is likely to be at work after graduation. According to the plan, the bank would be an agency of the federal government. It would borrow money from the government or from private sources. It is estimated that the scheme would be self-financing if borrowers paid 1 per cent of their gross income for a period of thirty years.

The scheme is likely to excite interest elsewhere than in the United States. In Britain, for example, there has recently been talk of providing some part of the cost of higher education by loans to students. Similar schemes already operate in Denmark.

## New Look for Welding

IN order to encourage the teaching of welding, Dr Richard Weck, director of the British Welding Research Association, has been appointed Visiting

Industrial Professor in the Departments of Mechanical Engineering and Metallurgy at the Imperial College of Science and Technology. This is the most obvious part of what will be an important scheme for collaboration in teaching and research between the Imperial College of Science and Technology and the British Welding Research Association.

The resources of the research association and the college are to be combined to expand the teaching of welding technology at all levels. Undergraduates at the college will be able to spend short periods of instruction at the association's laboratories, and the association's staff will help the college to provide courses of lectures for postgraduate students. A number of short refresher courses, of three to four weeks in specific fields of the technology, will be held for staff from industry by the college and association jointly. These will be held partly at the college and partly at the association's conference centre at Abington, near Cambridge. The scheme also envisages close collaboration in research; already work of interest to the association is being carried out at Imperial College. The facilities of the two departments of the college will be available to the association staff and the specialist equipment of the association will be available to the college. Younger staff members in the association will also be able to qualify for higher degrees from the college.

## Watching the Sun

A DISH aerial one mile in diameter which can adjust to the position of the Sun at one second intervals is clearly not a practical proposition, but a new radio heliograph two miles in diameter which was opened on September 22 at Calgoora, Australia, is designed to observe the Sun with equivalent resolution. Complete pictures of the solar disk showing great detail will be taken at one second intervals by the telescope, so that close observation of the rapid changes that occur during solar flares and sunspot activity will be possible. With an operating frequency of 80 megacycles, the resolution is thought to be about 2 minutes of arc. The telescope consists of 96 aerials set up in fixed positions round a circle two miles in diameter. Each aerial is a dish 45 ft. in diameter and is automatically driven to follow the Sun for 4 hours a day while the pictures are taken.

Signals from each aerial are amplified 100 times before being transferred by cable to the central point. The synthesis technique is the basis of the complicated calculations which are then made by computers, correlating the output of all possible pairs of aerials. The heliograph is part of the Australian Commonwealth Scientific and Industrial Research Organization's Solar Observatory, and was designed by Dr Paul Wild. It has taken five years to build and has been financed by donations of £230,000 from the Ford Foundation.

Within the circle of the radio heliograph at Calgoora the Physics Division of the CSIRO has set up a 12 in. optical telescope. It incorporates a specially developed filter which cuts down scanning time to only a few seconds, and should pick out details of areas only 250 miles in diameter on the Sun's surface 93 million miles away. The cine-magnetograph is under the direction of Dr R. G. Giovanelli, chief of the division, and is supported by the United States National

Aeronautics and Space Administration. A small telescope, which watches for solar flares as part of the world-wide patrol network, completes this array of tools for the Sun specialist.

## Water Games

THE Hydraulics Research Station of the Ministry of Technology at Wallingford (Berkshire) still finds that most problems in open channel flow must be solved by building models and running water through them. One result is that the station's programme of investigations at any time has a pleasing diversity. At present, for example, the station is studying the effects of very long waves in a model of the proposed Brighton yacht marina. The model is built beneath a two-dimensional array of lights, and the reflexions in the water with an exposure time equal to one wave period are photographed. This provides information about the maximum slope of the water surface. Opponents of the marina at Brighton will be distressed to hear that so far the work at Wallingford has shown no technical objections to the design.

The station is also intending to build a large model of Morecambe Bay to test the feasibility of a barrage and to determine the best position for one. The chief concern will be to determine the effect of the barrage on siltation and erosion in Morecambe Bay, particularly at the ports of Heysham, Fleetwood and Barrow in Furness. The investigation is part of a larger study being carried out by Sir Alexander Gibb and Partners for the Water Resources Board.

Civil disturbances at Hong Kong have not prevented the station setting out to study the building of a tunnel across the harbour by sinking prefabricated concrete sections, each 424 ft. long and weighing 30,000 tons. The sections would be floated into place and then sunk, a delicate operation with such enormous sections. If the hydrodynamic forces acting on the tunnel sections are not precisely known, there is a danger that the tunnel will either sink too fast or bob up again to the surface. The necessary information is being supplied by the use of a 'Perspex' model at Wallingford, built to a scale of 1 in 100. There is also a feasibility study of the disposal of London sewage by pipeline rather than by boat, and an attempt to devise a way of removing a sand bar at the mouth of the Baram River in Sarawak so as to make the river navigable for at least 60 miles.

All these projects are done on direct contract, and represent about half the work of the station. The other half is divided equally between research work with no specific client in mind and more basic studies of hydraulic science. Theoretical work at the station has shown, for example, that it is possible to obtain perfect dynamic similarity when modelling the process of sediment transport, and two channels of the same shape but different sizes have been built to demonstrate this. This work provides a theoretical basis for the large models. The station costs about £500,000 per year to run and last year earned £308,000. Recently, as part of a review by the Ministry of Technology of research establishments, the station was asked to justify its existence to British industry by calculating how much money was saved as a result of work at Wallingford. By conducting a survey of the small number of projects where accurate costings are possible,

the director, Mr R. H. C. Russell, claims to have shown a £7 million saving to industry for an expenditure of about £700,000.

## Linneans Wanted

A LITTLE public relations can often do a lot of good, as the Linnean Society seems to have decided. The society, formed in 1788 by a splinter group from the Royal Society, concentrates on the biological sciences. It has now decided, in co-operation with the Department of Extramural Studies of London University, to run a series of lectures on the "Historical Background to Modern Botany" in an attempt to become better known and to attract more members, particularly keen amateurs. It is also running a natural history education programme with a course of lectures for 120 promising sixth form girls and boys, and has started a student associateship of the society to attract young members between the ages of 18 and 24.

The society also intends to launch an appeal for £100,000. With the money it hopes to rehouse the valuable Linnaeus Collections and its library of 90,000 books, and to adapt the rooms in Burlington House which it acquired when the Royal Society moved out.

## More Nuclear Safeguards

THE US Atomic Energy Commission has provided further evidence of its concern for the safeguarding of nuclear materials of various kinds by its decision to establish a committee to provide technical advice on the subject. The chairman will be Mr J. Palfrey, a lawyer at Columbia University, who was a member of the AEC for four years until 1966. The fourteen ordinary members of the committee include scientists, industrialists and lawyers. The AEC says that it will rely on the committee for advice about the application of safeguards to particular problems as these occur, as well as for the development of general policy. Although the setting up of such a committee was not explicitly suggested by the Lumb panel on safeguards procedures which reported earlier this year, it is part and parcel of what seems to be a thorough review of safeguards procedures by the AEC.

At least three separate lines of argument have given impetus to this tendency. The growth of the nuclear power industry in the United States is spectacular enough in itself to account for a renewal of interest in the subject. The amendment of the Atomic Energy Act which allows private companies to own nuclear fuels and to process them has emphasized the need for explicit criteria for a sharp line between the permissible and the illicit, and for means of ensuring that these criteria are observed. (Already one plutonium reprocessing plant and a number of fuel fabrication plants are operating under private ownership in the United States.) But it is also plain that international pre-occupation with the treaty to limit the spread of nuclear weapons has made necessary a more explicit policy on safeguards, although the AEC as such can do very little in that respect but stand on the sidelines and show willing.

This is why the chief interest of the work of the new committee will be the way in which it helps to provide national precedents for what may eventually

become international agreements on safeguards. In this sense it may already be significant that the AEC has decided to assign permanent inspectors to some at least of the privately owned processing plants—the plant operated by Nuclear Services Incorporated for extracting plutonium from spent fuel, for example. Developments like these could well nudge the IAEA into the conviction that itinerant inspectors like those now based at Vienna may not always be able to exercise detailed control. There will also be great interest in the criteria for deciding what imprecisions in the safeguards system can be safely tolerated, which it will presumably be a part of the new committee's job to develop. It is less certain whether the committee will also pick up one of the more controversial recommendations of the Lumb panel—the notion that there should be stiff fines and prison sentences for people participating in breaches of the safeguards system. At first sight, there may be a little too much of James Bond in the suggestion that infringement of the regulations should expose people to the risk of five years in prison or fines of \$10,000, but if there are not criminal penalties of this kind, it may occasionally be extremely hard to know how conspirators should be dealt with under existing laws.

## New Reactors

THE United Kingdom Atomic Energy Authority's steam generating heavy water reactor at Winfrith, Dorset (*Nature*, **214**, 867; 1967), has been loaded with fuel and heavy water and the first stage of operation, at low power, has been reached. Construction started in May 1963, and the reactor is expected to be operating at full power by the end of this year, when it will deliver 100 MW of electricity into the national grid. The AEA has high hopes of the reactor in the export markets. In the size range 300–500 MW, the economics and fuelling of this reactor make it particularly attractive. New Zealand, which hopes to have about eight reactors by the late seventies, has already sent engineers to look at it.

The reactor has a pressure tube construction with heavy water as the moderator and natural water as coolant. Although the prototype at Winfrith uses slightly enriched uranium oxide fuel, the actual production reactor will use natural uranium. This may be an attraction in countries where people fear dependence on a small number of sources of fuel supply. The steam generated in the core passes directly to a turbo-alternator to generate electricity and not through a secondary cooling system.

The authority's VIPER reactor, intended for research, is also now in operation at Aldermaston, where it was designed and built. The reactor produces much more intense pulses of neutron and gamma radiation levels than those available from present steady state research reactors. At full power, there are  $3 \cdot 10^{17}$  fissions producing, in 500  $\mu$ sec,  $10^{15}$  neutrons/cm<sup>2</sup> and a gamma-ray dose of 30,000 rads. The reactor power rises to a peak of 20,000 MW. Because the reactor does not have forced cooling, it must be allowed to cool at its own speed, and can generate only two pulses a day.

Pulses are produced by the rapid movement of a uranium fuel rod into and out of the core. This increases the reactivity of the reactor into the prompt

critical region. The power in this region increases rapidly—doubling every 70  $\mu$ sec. The neutron pulse is limited by the inherent characteristics of the reactor. First, as the temperature rises the fuel expands, thus increasing the loss of neutrons by leakage. At the same time the effective width of the resonance capture peaks of uranium-238 increases, which implies that more neutrons are captured and the probability of fission is reduced.

The VIPER reactor differs from earlier fast pulsed reactors, such as the American Godiva, because the broadening of the resonance lines at higher temperatures, itself a Doppler effect caused by thermal motion, provides a large part of the temperature dependence of the reaction. This same effect is an important inherent safety factor in fast breeder reactors of the type now being considered for power stations.

## Britain's Chemist

THE annual report of the Laboratory of the Government Chemist for 1966, just published (HMSO, 15s.), describes the work which is being done by the staff of 426. Customs and excise work accounts for 42 per cent of everything, and covers a wide field, from the detection of prohibited substances in food and tobacco to decisions on the nature of goods for duty purposes. The laboratory also produces evidence in cases of drug smuggling. Research is at present going on into methods of analysis of such spirits as whisky, largely because of the need for certificates of authenticity for export cargoes.

The division dealing with environmental health and safety investigates a large number of possible sources of hazard and carried out twenty-four investigations during 1966, mostly on such topics as pesticides, fluoridation and drug samples. The laboratory endeavours to publish the results of its analyses if, in doing so, any doubts about public safety will be allayed.

Because so much of the work of the laboratory is analytical, it is hardly surprising that a substantial part of the research carried out in the new Research Division concerns analysis techniques and the possibilities of mechanization in this field. There are, however, other topics under consideration. Dental fillings and cement have come under scrutiny, and £14,000 has already been spent in trying to make improvements.

The laboratory received 240,000 different enquiries during the year, on subjects ranging from oysters and sheep dip to preservatives and effluent. To answer these questions, and to keep in touch with the public and maintain laboratories in Cyprus, Singapore and Antwerp, a total of £950,000 was spent.

## Keeping Flukes at Bay

SCHISTOSOMIASIS, caused by infection of blood and internal organs with parasitic flukes, has received much attention in the laboratory, while control measures have been progressing slowly. In a report on the epidemiology and control of the disease, a World Health Organization Expert Committee summarizes the knowledge available in the hope that it will help to co-ordinate the efforts of laboratory and field workers. (*WHO Technical Report Series*, No. 372.)

Flukes of the family Schistosomatidae spend part of their life cycle, the miracidium stage, as parasites of aquatic snails. The free swimming cercaria stage passes into the water and the life cycle continues when the cercaria enters the blood stream of a second host, which may be man. The eggs pass out in the faeces and from them come the miracidia. In tropical regions agricultural schemes which involve irrigation are increasing the prevalence of schistosomiasis; when water is supplied to an area it becomes capable of supporting larger populations of snails and humans, and the possibility of transmission of parasites is greatly increased. In Brazil the disease caused by *Schistosoma mansoni* has spread into the southern states after agricultural development involving irrigation. In Africa there has been an increase in the occurrence of new foci of *S. mansoni* and *S. haematobium* in areas where there are many small systems for improving water supply. In the past schistosomiasis has been referred to as a rural disease, but transmission can now occur in urban areas if conditions are favourable.

Community surveys designed to assess the effect of schistosomiasis on health have shown the situation to be more serious than was realized. Radiological studies have revealed a high prevalence of urological lesions in young people, and the occurrence of the lesions shows good correlation with data concerning egg production. This has necessitated new thinking about infection with *S. haematobium* which was previously thought to be benign.

Control programmes have varying degrees of success according to ecology, budget and available manpower. In some areas the objective may be the modest one of limiting the spread of the infection. In favourable circumstances transmission may be reduced, or the disease may be eradicated. The committee recommends that one of these three objectives be chosen before a control programme is launched. Snails can be controlled most effectively by chemical means. There are several molluscicides available, for example niclosamide and copper sulphate, and the choice depends on the conditions of the habitat. It is essential to distribute the chemical evenly throughout the water so that all snails and their eggs are killed. Some molluscicides have harmful effects on other organisms, and the committee considers that the biocidal aspects of widespread use of molluscicides must be investigated.

Biological control has been successful in Puerto Rico, where the snail *Marisa cornuarietis* has been introduced; it competes for food with the schistosome host *Biomphalaria glabrata* and consumes the eggs of the second snail. Combination of chemical control with this means of biological control has almost eliminated *B. glabrata* in some areas, which suggests that biological control may be very useful if used together with other measures.

## Rubber Magnets

ONE of the most intriguing exhibits at a symposium organized this week by the Institution of Electrical Engineers on magnetic materials and their applications were magnets made of rubber. They were described by Mr A. Edwards, Deputy Managing Director of James Neill and Company (Magnets and Steel), the company which manufactures them.

The rubber magnets consist of ferrite particles compounded with rubber or plastic—efforts to bond crushed magnet alloys have always failed. The rubber base can be loaded with as much as 90 per cent of ferrite by weight without losing its flexibility, and the ferrite retains most of its magnetic properties if the loading is above 80 per cent. At a loading of 92 per cent, for example, the rubber magnet has a remanence of 1,628 gauss, and a maximum attractive power of 25.3 oz./sq. in., quite adequate for a number of purposes. The rubber magnet is produced in the form of a sheet 0.04 in. thick, 18 in. wide and 50 ft. long, and is magnetized on one surface by a pattern of stripes of alternate north and south polarity. In the technique used by James Neill and Company, the alternate stripes of magnetization are each twice as wide as the thickness of the sheet. In this way it is possible to produce a thin sheet of unlimited area which is magnetized all over. Mr Edwards suggested a variety of uses for the magnetic material. It can be used to hold the doors of refrigerators shut, or, more unusually, as a means of attaching symbols to a steel display board. Although the rubber magnets are brown, their appearance can be improved by bonding a layer of polished PVC to the non-magnetized surface. Since the PVC surface accepts screen printing or writing, Mr Edwards hopes that a vast new market in inexpensive magnetic charting or recording boards may be opened up. The sheet is also used in the sumps of engines or gearboxes, to pick up wear particles, and could be used as the stator in small electric motors.

## Handbook for Desalinators

AN investigation of integrated power stations and desalination plants has just been completed by Applied Research and Engineering Limited (AREL)—a subsidiary of the Capper-Neill Group. The report was commissioned by the International Atomic Energy Agency and is due to be published early in 1968. It is a step by step guide to costs which no would-be builder of desalination plants should be without. The costs of the various processes involved in a plant of this kind have been worked out separately, so that the feasibility of a particular scheme can be calculated before an expensive full scale enquiry is begun. Throughout the report, however, it is made clear that individual circumstances can markedly influence costs. The cost of labour, for example, varies from place to place.

Dual plants make economic use of low grade waste heat from electricity generating stations to purify sea water, but their chief advantage is that it becomes economic to build larger power stations than could be justified by the demand for electricity by itself. But scale brings economies. At present the multi-stage flash evaporator is considered to be the only economic process for purifying sea water, and in the report it is studied in combination with three types of nuclear power reactors—light water, gas cooled and fast breeder reactors. The costs of steam in small desalination plants are high, so that for comparison fossil sources of heat are included in these circumstances. A variety of conditions is considered, up to the limiting case in which water is the important product and the electricity produced is just enough to keep the plant running.

When the overall costs have been calculated, they must be allocated between the products. The IAEA has given several possible but purely arbitrary methods in its Technical Report Series (No. 69) and of these AREL has chosen a system the effect of which is to use whatever savings there may be because of economies of scale to reduce the cost of electricity rather than the cost of water. As a result, the cost of water is higher than in some other methods of cost allocation, but the somewhat arbitrary nature of this apportionment of costs is emphasized throughout the report. This, no doubt, is why it is suggested that one authority operating both parts of the plant may be the best solution.

There seems to be very little to choose between different types of reactors. The report includes detailed calculations of the costs of using gas cooled and light water reactors in conjunction with back pressure turbo alternators. For an output of 100 million US gallons of water a day and a power output of 300 megawatts, the costs of water and power produced by the two kinds of reactors are almost identical. The power is reckoned to cost 3.4 mills per kilowatt hour (1 mill, \$0.001) from the light water reactor (exhaust temperature 230° F.) and 3.6 mills per kilowatt hour for the gas cooled type (exhaust temperature 270° F.). The cost of water is 33 cents per 1,000 US gallons for the light water reactor and 35.2 cents per 1,000 US gallons for the gas cooled version. The report also sets out to predict what advantages there will be when fast breeder reactors are in service—both electricity and water may be reduced in cost by 30 per cent.

## A Role for Melanoproteins

from our Microbiology Correspondent

WITHIN the past few years some attention has been devoted to that intractable and so-called secondary group of microbial products, the melanins. Attempts to describe these polyphenolics chemically have been largely unrewarding, while the definitions of their physiological role in micro-organisms have scarcely progressed beyond the stage of intelligent speculation. Now, however, several functions of microbial melanins or melanin-protein conjugates are being discovered. The presence of melanin in the walls of certain fungi appears to be an important factor in resistance to lysis by soil bacteria—a thesis developed most notably by Alexander's group at Cornell University (for example, Bloomfield and Alexander, *J. Bact.*, **93**, 1276; 1967). Again, cell and spore walls impregnated with melanin confer protection against ultra-violet irradiation and there is a frequent correlation between ecological distribution, especially of fungi, and presence of the pigment.

The current issue of the *Journal of General Microbiology* (**48**, 269; 1967) includes a report from R. C. Hignett and D. S. Kirkham on yet another function of microbial melanin—an extracellularly produced melanin or, more precisely, a melanoprotein. These workers have studied the relationship between pathogenicity and culture characteristics of *Venturia inaequalis*, the causal fungus of apple scab. Several fungi, both saprophytes and pathogens included, produce dark extracellular pigments—usually termed "presumed melanins"—when grown in submerged culture. It has been impossible to say whether or not such synthesis is a

cultural artefact, but the results of Hignett and Kirkham, argue against such a conclusion at least in the case of *Venturia*.

The *Venturia* melanoprotein was fractionated on the basis of ethanol solubility and the fraction insoluble in 75 per cent ethanol (N75) was further resolved by gel filtration. The effects of these melanoproteins were studied by injecting them into the petioles of young apple plants and by using non-toxic indicator substances such as glucose labelled with carbon-14. Two important effects were observed. First, there was a marked accumulation of the glucose in the vascular system of the inoculated leaf, whereas the intervenal tissue was unpermeated. The second effect was a strong inhibition of  $^{14}\text{C}$  glucose uptake accompanied by an even permeation throughout the leaf. These effects seem to be specific, for a variety of proteins similarly injected did not elicit these responses.

Later experiments have tested whether metabolite transport in plants infected with fungus is disturbed in the same way as plants treated with melanoprotein. Twelve days after fungal inoculation the labelled glucose was accumulating at the sites of presumptive lesions and two days later the distribution of the glucose and the sporulating lesions were identical. Further evidence for the involvement of melanoprotein in lesion development was provided by its co-inoculation with *Venturia* spores into test plants. A marked stimulation of lesion development occurred when certain fractions of N75 were applied in this way. The melanoprotein fraction responsible for the second effect also has directional properties and prevents movement of metabolites towards the midrib from where they might be transported away from the leaf. Although an accumulation of plant metabolites at lesion sites has been reported in several host-parasite systems, it was not known whether such activity was under the control of host or pathogen. Hignett and Kirkham's observations are therefore an important contribution to the understanding of phytopathogenicity and illustrate a highly sensitive mechanism by which at least one pathogen redirects the metabolism of its host to its own advantage.

## Kinds of Ribosomes

from our Molecular Biology Correspondent

WITH the isolation of mitochondrial ribosomes by Küntzel and Noll, reported last week in *Nature* (215, 1340; 1967), a clearer pattern of the evolution of the ribosome is beginning to emerge. The mitochondrial ribosomes turn out to have a sedimentation coefficient of 73S, and to contain RNA components of 20.5S and 16.4S. They therefore resemble chloroplast ribosomes (67S, with RNA components of 20.8S and 15.7S under the same conditions) and bacterial ribosomes, of which the most familiar example, from *E. coli*, sediment at 70S, with RNA of 21S and 16S. The possibility that chloroplasts and mitochondria enjoy an independent existence within the cell, and that they originated as some type of symbiotic bacteria, has aroused wide interest.

Apart from size, various other systematic differences between the different classes of ribosomes may, however, be noted. Thus bacterial ribosomes contain about 50 per cent of protein, whereas in plant and animal ribosomes this figure seems always to be near 60 per

cent. In terms of base composition of the RNA, animal ribosomes show considerable differences from all others, most noticeably in a consistently higher content of cytosine. It is also relevant that the molecular weight ranges within the above mentioned classes are in fact quite broad—the spread of 66S to 73S in bacterial ribosomes on going from the photosynthetic bacterium *R. rubrum* to *B. licheniformis*, corresponds to a difference of about 25 per cent in molecular weight. (The sedimentation coefficient varies roughly as the square-root of the molecular weight.) Although many of the older data stand in need of revision, and the conditions under which different authors have worked are not always sufficiently alike to permit good comparisons, there is a general tendency, in particular in micro-organisms, of increasing molecular weight with evolutionary status. (Some interesting speculation along these lines is to be found in the article by Küntzel and Noll.)

How these ribosomes differ functionally is a subject of which the surface has so far hardly been scratched, but some interesting experiments on the functioning of heterologous protein synthesizing systems have recently been reported. A revealing study comes from Parisi *et al.* (*J. Mol. Biol.*, 28, 295; 1967), who have examined poly-U directed cell-free systems with components from two disparate species of bacteria, *E. coli* and *B. subtilis* (70S ribosomes), and from a micro-organism (yeast), a higher plant (bean seedlings) and an animal tissue (rat liver), all having ribosomes of the 80S type. Although the combination of ribosomes of one category with the supernatant enzymes from cells of the other kind gave no significant incorporation, there was substantial incorporation whenever components were mixed within one group. The effect was consistent and striking. To show that the limiting factor was not the failure of synthesis of the aminoacyl-tRNA in the heterologous systems, the experiments were also performed with pre-formed phenylalanyl-tRNA. The source of the latter (whether from the one type of cell or the other) had little effect on the efficiency of incorporation of the phenylalanine. It was also demonstrated that the incompatible systems did not degrade the heterologous aminoacyl-tRNA, neither were any specific inhibitors present in the heterologous supernatants, since these did not interfere when added to functional homologous systems. It appears most probable, therefore, that ribosomes recognize only the relevant protein synthesizing enzymes from sufficiently closely related cells. The similarities between ribosomes within the 70S and 80S groups therefore go beyond their common physical characteristics, and well into the realm of function.

## Peptides without Ribosomes

from our Cell Biology Correspondent

ANTIBIOTICS like the gramicidins, tyrocidine and licheniformin are short peptide chains of between 10 and about 40 amino-acids synthesized by spore forming bacteria at certain stages in their life cycle. Apart from their antibiotic activity, these peptides are of very great interest because synthesis of them does not involve ribosomes, mRNA and all the other machinery of protein synthesis. (A group working at the University of Hawaii had claimed that gramicidin is synthesized on ribosomes, but they have recently retracted

this view, having failed to repeat their earlier experiments (Bhagavan *et al.*, *Biochemistry*, **5**, 3844; 1966.) Furthermore, these antibiotic peptides contain either D isomeric forms of amino-acids or amino-acids, such as ornithine, not present in proteins.

If the information for the sequence of the amino-acids in these peptides is not coded in an mRNA molecule, where does it reside? One obvious possibility, suggested by Mach *et al.* (1963), is that the enzymes, or multi-enzyme complexes which synthesize the peptides, have sufficient structural specificity to recognize the unfinished peptide chain and the next amino-acid that has to be incorporated. This hypothesis cannot be tested until an enzyme system has been isolated and purified, and in *Biochemistry* (**6**, 2552; 1967) Tomino *et al.* report some progress in this direction. They have isolated and partially purified an enzyme system from *B. brevis* which, when supplied with the necessary amino-acids, ATP,  $Mg^{++}$  ions and reducing agent, synthesizes the cyclic decapeptide gramicidin S. The system is devoid of ribosomes and is not inhibited by puromycin, chloramphenicol or RNase, which inhibit protein synthesis. Column chromatography resolves the enzyme system into two fractions, I and II, neither of which alone will synthesize gramicidin S or any intermediary peptide. Fraction II appears to be a racemase which in the presence of ATP converts L-phenylalanine into activated D-phenylalanine, which in the presence of both fractions is incorporated into gramicidin S. Added D-phenylalanine is incorporated directly by the complete system, but surprisingly when both D- and L-phenylalanine are present in the incubation mixture it is the L-phenylalanine that is preferentially incorporated after ATP dependent racemization.

Obviously this work is only a beginning. It is not yet known even if splitting of ATP is necessary for the formation of peptide bonds in gramicidin S, but further purification of these enzyme fractions should answer this question and may well show whether or not the sequence specificity resides in the structure of the enzyme complex.

## Planetary Nebulae

ABOUT 2,000 planetary nebulae have so far been identified in the galaxy. They emit light in various characteristic spectral lines, and when resolved are often seen to have a ring-like or butterfly form. The typical planetary nebula has a mass between 0.1 and 0.5 of the mass of the Sun ( $M_{\odot}$ ) and linear dimensions of order 0.1 parsec. Planetary nebulae are therefore quite different from ordinary HII regions, which are much larger and more massive and which are always associated with a group of O or B stars. A planetary nebula usually has just one exciting star with a luminosity between  $10^2$  and  $10^4$  times that of the Sun and a surface temperature between  $5 \times 10^4$  and  $10^5$  degrees Kelvin.

This kind of star is quite different from an unevolved O or B star. Its mass is somewhat less than a solar mass instead of 20 or 30  $M_{\odot}$ , its radius is much smaller than that of the Sun and its energy source is the transmutation of  $^4\text{He}$  into  $^{12}\text{C}$  rather than the conversion of H into  $^4\text{He}$ . In other words, the central star of a planetary nebula is a highly evolved star, now moving towards the left and near the end of the horizontal branch of the Hertzsprung-Russell diagram. Even

together with its central star, a planetary nebula has insufficient mass to have condensed by gravitation out of the interstellar medium at large; it follows that the star must have formed at some much earlier epoch as part of an association which has now dissolved, and that the material of the nebula must have been ejected at some stage in the history of the central star, perhaps during the evolution from the red giant stage.

Simple observations can lead to a remarkable amount of information about the physical state of a planetary nebula. The first step is to find the typical electron density  $n_e$  by measuring the intensity ratio of the emission lines of  $O^+$  at  $\lambda\lambda$  3726, 3729 Å. The ratio is different at low and at high values of  $n_e$  and is particularly sensitive to change near  $n_e \approx 10^4 \text{ cm}^{-3}$ . Many nebulae are found to have electron densities of about this order.

Next, it is possible to determine the emission measure ( $EM$ ) by observing the surface brightness of the nebula, either in the radio continuum or in the Balmer lines of hydrogen. The  $EM$  is proportional to  $n_e^2 l$ , and so one can deduce a typical linear scale  $l$ ; knowing also the angular size  $\theta$  of the object, its distance  $R (=l/\theta)$  may be deduced. The distance in turn fixes a value for the absolute visual magnitude  $M_v$  of the central star in terms of its apparent magnitude  $m_v$ .

Photographs from the Mount Wilson and Palomar Observatories.

NGC 6720. Planetary nebula ("Ring") in Lyra. Green (top) and yellow (bottom) light. 200 in. Hale.

The nebula may be used as a detector of photons in the far ultra-violet by observing and interpreting the ionization balance of various constituents such as He, He<sup>+</sup>, He<sup>++</sup>, O, O<sup>+</sup>, O<sup>++</sup> and so on. The balance is determined by the luminosity of the central star in the far ultra-violet; having found this luminosity one can estimate the effective temperature of the star.

In another connexion, the distances  $R$  fix the positions of the various nebulae with respect to the galaxy, and it appears that they are distributed like typical members of Population I stars. Further, there may be disagreement between the emission measures as given by radio and optical methods; if so the discrepancy must be ascribed to extinction in the visual range of wavelengths by interstellar dust grains, and observations for different objects lead to information about the distribution of dust in the galactic disk.

The central stars of planetary nebulae follow a well defined sequence of stellar evolution in the Hertzsprung-Russell diagram, and take about  $10^4$  years to move through the range in which they are associated

with planetary nebulae. Theoretical models agree tolerably well with the observed data. At the end of the sequence, the central stars approach the region of the white dwarfs. Exact numbers are not yet agreed, but at least a substantial minority of white dwarfs must have evolved in this way.

In summary, the overall properties of planetary nebulae are now well understood, but this understanding is based on rather primitive theoretical models. For example, it is often assumed that planetary nebulae are spherical in shape, and this is obviously not so. Work should now be started which is more realistic and allows for dynamical effects. For example, it seems that Lyman- $\alpha$  radiation is produced freely in a nebula and cannot easily escape. Does the resulting build-up of radiation pressure have an important mechanical effect? Can one understand the ring-like or butterfly-shaped appearance of many planetary nebulae in terms of some symmetry property of the central star, or of the original nebula? What is the origin of the features with a very fine structure which are seen in so many nebulae?

## Computerized Library of Deep Sea Soundings

by

MENACHEM DISHON\*

Goddard Institute for Space Studies,  
NASA, New York

BRUCE C. HEEZEN

Lamont Geological Observatory  
and Columbia University,  
Palisades, New York

More than a million deep sea depth soundings have been assembled in a computerized library which is to be used to make a new average ocean depth model.

THE work reported here has been prompted by the need for an average model of ocean depth for numerical computations on a world-wide basis. Such a model is necessary, for example, in dynamic problems of sea motion such as the study of ocean tides and the propagation of tsunamis, in geodesy in general and in the spherical harmonic analysis of earth topography. A second and more direct use is to provide a more efficient method of compiling and plotting soundings recorded in a variety of units, scales and formats. Once the sounding profiles are digitized, the variety of charts and vertical profiles required in physiographic studies<sup>1</sup> can be prepared by machine. This work, until recently, was all done by hand. A third use relates to quantitative textural analysis of topography (slopes, wavelengths, amplitudes) and to detailed hypsometric studies—subjects now of increasing interest to oceanographers<sup>2</sup>.

We now have access by computer to a world-wide coverage of more than 1 million deep sea soundings. It is the purpose of this article to provide a general account of the methods used in digitizing, processing and evaluating these data, and to indicate some of the applications for this library.

In 1961, one of us<sup>3,4</sup> devised a method to use irregularly spaced soundings to compute average ocean depth values for the areas prescribed by any regular grid. To test the method, the sounding nearest the intersection of each 1° grid line (where available) was selected from hydrographic

charts and bathymetric maps and used to compute the average depth for each 1° square on a Mercator grid. This provided a tentative model ocean for numerical computations of global, geophysical character. The results were so encouraging that we decided to launch a large scale project for computing improved depth averages. After considering the number of soundings available for the world ocean, we decided that a model based on 1 million points was a realistic initial goal.

Since the 1920s virtually all deep-sea soundings have been obtained with echo sounding methods. The echo soundings collected in the data libraries of the US Naval Oceanographic Office, the Woods Hole Oceanographic Institution, the Scripps Institution of Oceanography, the Lamont Geological Observatory and other oceanographic institutions are recorded in units of 1/400 sec travel time; this unit is known as the standard unit ( $t_s$ ) or the nominal fathom. To obtain a value approaching true depth, a correction for the geographic variation in vertical sound velocity is made according to a standard table, and these corrections may be as large as 600 m. Such velocity corrected depths are not completely accurate because of imperfections in the tables, seasonal variations and other factors. Soundings recorded on charts by the British Commonwealth hydrographic departments usually include such corrections. In addition to these general procedures, individual institutions or individual workers throughout the world have introduced other units equal to 1/420, 1/750, 1/725 sec and have adopted tables other than the standard one to obtain "corrected depths". Because all

Such profiles are a convenient way for presenting the essential information required in physiographic studies of the ocean floor. Depth (horizontal co-ordinate) in fathoms, distance (vertical co-ordinate) in nautical miles. Vertical exaggeration is 100 : 1.

echo soundings are measurements of time, accurate information concerning the units and corrections applied and the type, scale and ultimate accuracy of the recorder used is essential if soundings obtained from various sources are to be combined.

We used as the basic source information for our digital library the soundings on the master plotting sheets for deep sea soundings maintained by the US Naval Oceanographic Office, the Lamont Geological Observatory, the hydrographic departments of the United Kingdom, South Africa, Australia, New Zealand, the Netherlands and Germany.

Each sounding line was inspected for completeness and accuracy of position and depth, and assigned a rating based on general quality. Precision depth measurements accurate to 1 standard unit ( $t_e$ ), located by methods accurate to better than 1 nautical mile and recorded on charts with a spacing between soundings of no more than 2 miles, were given the highest rank. Soundings of unknown origin, scattered soundings, and soundings of known origin where accuracy was less than 100  $t_e$  or spacing more than 15 miles were in general not included in the library.

Soundings were recorded on punched cards with semi-automatic instruments known as  $x$ - $y$  co-ordinate digitizers with a precision for recording co-ordinates of 0.001 in. In this procedure, the recording head was set over the sounding to be read from the plotting sheet. Its depth value was punched by operating a keyboard and its co-ordinates were recorded automatically. The whole process is subject to human error, so verification is imperative. To do this all digitizations were done twice, preferably by two different operators. The two sets of digitized data were then checked one against the other for agreement within predetermined limits of tolerance. This procedure has the advantage that the verification can be done completely automatically on an electronic computer. Initially we used an IBM 7094 computer and later an IBM System 360 Model 75.

For a quick check on position errors, the tracks were plotted either at a reduced scale or at the original scale, and inspected for errors (Fig. 1). By examining computer-plotted vertical profiles gross discrepancies and inconsistencies were eliminated. Position plots and profiles of the digitized tracks were generated with the aid of a cathode ray tube plotter ( $s-c$  4020). This device, peripheral to the computer, reads computer-generated magnetic tape from which it produces the plots and depth profiles on 7.5 × 7.5 in. frames. Position plots and vertical profiles of all tracks are incorporated in the bathymetric library.

The results of the recording, after verification and corrections, are stored on magnetic tape. For each sounding, the following data are recorded: (1) Co-ordinates—latitude and longitude. (2) Sounding (as

recorded on source sheet) and units ( $t_e$ ,  $fm$ ,  $m$ , etc.). (3) Source sheet number. (4) Source track documentation number. (5) Source country. (6) Reliability rating.

We use an auxiliary programme for applying or removing corrections for the velocity of sound according to Matthews's tables<sup>5</sup>.

The library now includes over 1 million points from more than 8,000 track segments originally plotted on more than 2,000 source sheets. For every individual sounding-track segment a location plot is included in the library, as well as lists of co-ordinates, depth values, and pertinent source and technical data for each sounding. Vertical profiles have been prepared at an exaggeration of 100:1 for more than 2 million miles of sounding tracks (Fig. 2).

Such a large library necessitates an extensive index. Sounding tracks have been compiled for more than 700 plotting areas according to the US Naval Oceanographic Office numbering system. The library includes lists of all tracks for each area as well as complete listings of source information, including original scales, serial numbers and dates entered. Data from the expeditions of the Lamont Geological Observatory and the US National Science Foundation's research vessel USNS Eltanin are continuously fed into the library. Since 1966, all soundings data acquired by the US Naval Oceanographic Office have been routinely digitized with a system compatible with our library, and survey ships have recently begun collecting bathymetric data in digital form. This new information can be quickly incorporated by machine with data already in the library.

The data library will now be used to construct a new average ocean depth model for use in tidal studies and other global applications. It has already provided plots and profiles for deep sea physiographic studies and will be employed in further quantitative studies of submarine topography.

This work was supported in part by the Office of Naval Research, US Navy and the US National Science Foundation. One of us (M.D.) holds a National Academy of Sciences—National Research Council resident research associateship with the US National Aeronautics and Space Administration.

We thank Troy Holcombe for valuable assistance.

## The Making of a Scientist

by

H. A. KREBS

Scientists are not so much born as made by those who teach them research, which argues for the perpetuation of centres of excellence. This was the theme of this address by Sir Hans Krebs at the inauguration of the Department of Biochemistry at the University of Newcastle upon Tyne earlier this year.

I BECAME interested in my subject because students have asked me from time to time: "How does one become a Nobel laureate?" I have never before attempted to answer this question because I felt unable to offer an

impromptu comment, but when the same question repeated itself I began to reflect on possible answers.

First, I must criticize the question as not being quite appropriate. What is appropriate is the related question:

"How can distinction, or excellence, be attained in science?". Nobel awards are to some measure a matter of good luck, because their number is too small to do justice to all who would merit an award. A methodical way of finding an answer to the modified question is to study the history and characteristics of scientists of distinction. For this purpose I need a convenient criterion of distinction and, despite what I have just said (and despite some personal embarrassment), I will use the Nobel award as a mark of distinction, for want of a better criterion.

If I ask myself how it came about that one day I found myself in Stockholm, I have not the slightest doubt that I owe this good fortune to the circumstance that I had an outstanding teacher at the critical stage of my scientific career, when from my twenty-fifth to my twenty-ninth year I was associated with Otto Warburg in Berlin. He set an example in the methods and quality of first-rate research. Without him I am sure I would never have reached those standards which are a prerequisite for being considered by the Nobel Committees. I will say a few words later on what in particular I feel I learned from him, but before doing this I would like to examine to what extent the importance of an outstanding teacher applies to other Nobel laureates.

Warburg himself was a Nobel laureate in 1931. He received the prize for his work on the chemical nature of a key enzyme in the reactions between molecular oxygen and foodstuffs in cellular respiration. I was lucky to witness this work from the closest quarters and to take a subsidiary part in it. What were the origins of Warburg's standards? In an autobiographical note<sup>1</sup> which he wrote in 1964, he remarked that: "the most important event in the career of a young scientist is the personal contact with the great scientists of his time. Such an event happened to me in my life when Emil Fischer accepted me in 1903 as a co-worker in protein chemistry. During the following three years I met Fischer almost daily and prepared, under his guidance, the first optically active peptides". So Warburg's experience and views are very much the same as my own. Let me follow up the story further.

Emil Fischer, Warburg's teacher, was one of the most outstanding chemists of his time. He was awarded a Nobel Prize in 1902 for his work on the chemical structure of sugars, the first of his long series of great achievements. Fischer in turn was a pupil and prolonged associate of another Nobel laureate, Adolf von Baeyer, who received the Nobel Prize after Fischer in 1905, for his discoveries in the field of the chemistry of dyestuffs, in particular for the synthesis of indigo.

## Teachers

Since Nobel awards began only in 1901 this criterion of excellence cannot be used for the assessment of excellence in the nineteenth century, but the scientific "genealogy" of earlier teachers and pupils in Fig. 1 shows that von Baeyer was a pupil of Kekulé (famous for his contributions to the structure of organic compounds, especially the ring structure of benzene), and that Kekulé was a pupil of Liebig (who laid the foundation of organic chemistry). Evidently there was also an association with very distinguished teachers in the earlier generations of scientists; had Nobel awards existed in their time, Liebig and Kekulé would certainly have been laureates.

Liebig has provided his own testimony on the importance of a great teacher. He was a pupil of the French chemist Gay-Lussac, the discoverer of some of the fundamental laws of the behaviour of gases. At the time of Gay-Lussac and the young Liebig, Paris was the centre of Continental science and of Continental chemistry in particular. Liebig worked under him in Paris and referred to this experience<sup>2</sup> in the following terms. "The course of my whole life was determined by the fact that Gay-Lussac accepted me in his laboratory as a collaborator

and pupil." This is almost the same wording as that of Warburg, written 100 years later. Gay-Lussac was in turn a product of the great French school of chemists, including in particular Berthollet, who pioneered in the concepts of combustion (abandoning the phlogiston theory in favour of the role of oxygen) and elucidated the chemistry of chlorine, ammonia and hydrocyanic acid. One of Berthollet's teachers was Lavoisier.

In every case the association between teacher and pupil was close and prolonged, extending to the mature stage of the pupil, to what we would now call post-graduate and postdoctoral levels. It was not merely a matter of attending a course of lectures but of researching together over a period of years.

## Genealogy

So my scientific "genealogy" as summarized in Fig. 1 drives home the point that, in many instances, distinction breeds distinction or, in other words, distinction develops if nurtured by distinction. This is further borne out very forcibly by a consideration of a more extended family tree of scientists. Fig. 2, derived from a chart exhibited in the Munich Museum of Science and Technology (Deutsches Museum), summarizes the genealogy of the Nobel laureates descended from von Baeyer, the pupil of Liebig, and this includes seventeen names. Outstanding discoveries can be associated with all the names. A fuller chart<sup>3</sup>, beginning two generations earlier with Liebig, contains more than 60 exceptionally distinguished names and includes more than 30 Nobel laureates.

Seeing this kind of agglomeration of laureates within a scientific family, the sceptic might well suspect a bias in favour of giving prizes to pupils of laureates. In short, does nepotism play a part in the awards? I hope everybody will agree that the answer to this question is an emphatic "No". The high standing, in the eyes of the world, of Nobel awards is derived from the general recognition of the absolute integrity of the Nobel Committees, and from the knowledge that these committees take a tremendous amount of trouble in finding the most worthy persons.

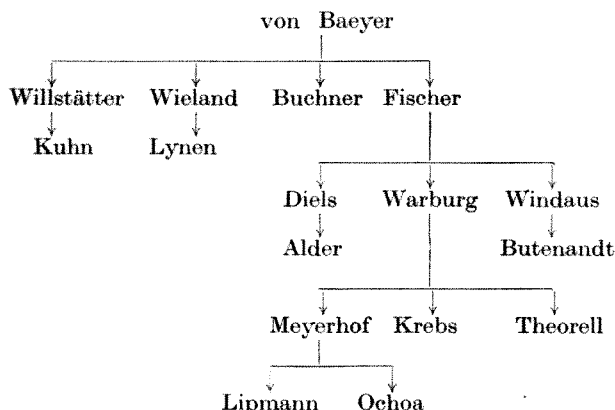

What, then, is it in particular that can be learned from teachers of special distinction? Above all, what they teach is a high standard of research. We measure everything, including ourselves, by comparisons; and in the absence of someone with outstanding ability there is a risk that we easily come to believe that we are excellent and much better than the next man. Mediocre people may appear big to themselves (and to others) if they are surrounded by small circumstances. By the same token, big people feel dwarfed in the company of giants, and this is a most useful feeling. So what the giants of science teach us is to see ourselves modestly and not to overrate ourselves. This is a general point.

Let me now try to be more specific and quote what individuals have themselves thought about the influence of their teachers. Warburg<sup>1</sup> in his autobiographical

The arrows indicate the teacher-pupil link. All members  
of this "family" are Nobel laureates

note summarized this with reference to his association with Emil Fischer: "I learned that the scientist must have the courage to attack the great unsolved problems of his time and that solutions can usually be forced by carrying out innumerable experiments without much critical hesitation." If I try to summarize what I learned in particular from Warburg I would say he was to me an example of asking the right kind of question, of forging new tools for tackling the chosen problems, of being ruthless in self-criticism and of taking pains in verifying facts, of expressing results and ideas clearly and concisely and of altogether focusing his life on true values. An earlier witness on this question of what one learns from an outstanding teacher was Kekulé who, in 1890, when he was 61, remarked that above all he learned from his teacher Liebig the habit of hard work. He related<sup>4</sup> that Liebig had told him, "If you wish to be a chemist you must be willing to work so hard as to ruin your health. He who is not prepared to do this will not get far in chemistry nowadays". Kekulé added, "For many years four, or sometimes even three, hours of sleep were enough for me". Kekulé, of course, went a bit too far, quite a lot too far, but I do think there is a great deal of truth in attaching importance to the capacity for very hard work.

### Opportunities

A recent witness on this question of what distinguished teaching can convey is Jacques Monod<sup>5</sup>, who received a Nobel Prize in 1965. In his Nobel Lecture he commented on the importance to him of a Rockefeller Fellowship which gave him the opportunity to work at the California Institute of Technology in the laboratory of Morgan. He describes the influence which the contact with the distinguished people meant to his development as a scientist: "This was a revelation to me—a revelation of what a group of scientists could be like when engaged in creative activity, and sharing it in constant exchange of ideas, bold speculations and strong criticisms: it was a revelation of personalities of great stature such as George Beadle, Sterling Emerson, Bridges, Sturtevant, Jack Schultz and Ephrussi, all of whom were then working in Morgan's Department." Morgan was at that time a Nobel laureate and Beadle became one later.

There is one more witness I want to quote in connexion with the special qualities of what leaders in a subject can teach. This is Otto Loewi, who was a Nobel laureate in 1936, a pharmacologist and physiologist. He said this about the leading physiologists of the nineteenth century and their influence on their pupils<sup>6</sup>: "They shared to the highest degree the qualities of contagious enthusiasm, broadmindedness and imagination, humility and deep devotion to their pupils. These are qualities which in themselves suffice to attract outstanding students. . . .

Besides the art of experimenting and observing, the pupils learned the ways of thinking required by science. They learned how to select the object to be explored, how to interpret and evaluate the results obtained, and how to integrate them into the whole body of knowledge. In this way students were not only made familiar with methods and facts, but were imbued with the general scientific spirit which shapes the pattern of the true scholar and investigator."

So, above all, attitudes rather than knowledge are conveyed by the distinguished teacher. Technical skills can be learned from many teachers and, like a modicum of intelligence, are, of course, prerequisites for successful research. What is critical is the use of skills, how to assess their potentialities and their limitations; how to improve, to rejuvenate, to supplement them. But perhaps the most important element of attitude is humility, because from it flows a self-critical mind and the continuous effort to learn and to improve. Also of great importance is the enthusiasm conveyed from teacher to pupil: it is the root of a large capacity for work; it makes the research worker look on research not as work but as a hobby and it also induces him to say "No" when he is faced with tempting diversions leading him to the "corridors of power" or travel on innumerable trips abroad.

### Question

I have referred to the importance of asking the right kind of question in choosing a research problem, avoiding those which may give a quick result and concentrating on those which are really worth while tackling. Paul Weiss<sup>7</sup> remarked: "The primary aim of research must not just be more facts and more facts, but more facts of strategic value". By strategic value he meant that an observation or an experiment should lead to the clarification of a problem or deeper insight into a phenomenon, or to the linking of previously unrelated facts and ideas. Goethe<sup>8</sup> expressed the same idea much earlier: "Progress in research is much hindered because people concern themselves with that which is not worth knowing, and that which cannot be known". Medawar<sup>9</sup> has recently stated very succinctly: "If politics is the art of the possible, science is the art of the soluble". How to select worthwhile soluble problems and how to create the tools required to achieve a solution is something that scientists learn from the great figures in science rather than from books.

I would like to underline, on the basis of my own experience, what Monod said about the importance of belonging to a group of scientists such as he found in the California Institute of Technology. Association with a leading teacher almost automatically brings about close association with outstanding contemporaries of the pupil because great teachers tend to attract good people. Students at all levels learn as much from their fellow students as from their seniors and this was certainly true in my own case. Warburg's laboratory at Dahlem, where I served my apprenticeship, was surrounded by other centres of distinction. It was in the same building as Meyerhof's laboratory and the contacts between the two biochemical groups were very close. My own contemporaries included many young people who later became outstanding scientists. There were Ochoa and Lipmann, who became Nobel laureates. There was Lohmann, who discovered ATP and the structure of co-carboxylase; there was Karl Meyer, who discovered hyaluronic acid; there were Hans Gaffron, David Nachmansohn, Dean Burk, Frank Schmitt, Ralph Gerard and Hermann Blaschko. Among the numerous other outstanding scientists working within a few hundred yards, and getting together regularly at the weekly colloquia, were Neuberg, Hahn, Meitner, Haber, Polanyi and Bonhoeffer.

There are many other examples of such centres of excellence and breeding grounds of scientists. Cambridge, for example, was a centre of excellence in physiology and

biochemistry in the early decades of this century because Foster, Langley, Hopkins, Barcroft and Adrian were each surrounded by a group of enthusiastic young people of great ability. Cambridge, of course, at the same time was also a centre of excellence in physics, thanks to J. J. Thomson and Rutherford.

No doubt Cambridge and Oxford owe some of their special standing to their size, which made it possible to assemble broadly based groups in a single subject at a time when provincial universities were usually restricted to very small departments with little scope for the cross-fertilization which occurs in the larger groups. It is gratifying to see the recent developments in the provincial universities which have removed this restriction and go a long way in providing a first rate environment.

What I have said so far is not merely a matter of historical reflexions. There are lessons to be learned, in particular by policy makers in the universities who aim at making universities into centres of excellence. As excellence in research is one of the main ultimate roots of all academic excellence, including that of undergraduate teaching, universities ought to do everything in their power to create opportunities for first rate research work by their staff. But do they? Or, being willing, are they given the means, in terms of facilities and cash, to do so?

### Leadership

In the course of this century there have been only two *really* fundamental advances in the sciences: the first was in the field of atomic physics, leading to the creation of quantum mechanics and the release of atomic energy. The second was in biology where the fusion of biochemistry, biophysics and genetics to form molecular biology has led to an understanding of basic biological phenomena which, only a generation ago, seemed beyond the reach of science altogether. When we compare the circumstances which led to these two great advances we find, as Max Delbrück<sup>10</sup> has pointed out, remarkable differences in the manner in which they have been achieved. Atomic physics was created almost exclusively within the framework of traditional university institutions, whereas in biology the modern developments have not come from the traditional departments of biology. They are largely the results of the efforts of chemists, physicists and biologists, who frequently worked in non-biology departments, and outside the universities. In Britain, decisive advances associated with the names of Wilkins, Crick, Watson, Perutz and Kendrew were made in the Medical Research Council units in London at King's College and at Cambridge, and both these units, financed by the Medical Research Council, were placed in physics and not in biology laboratories. In France, the decisive contributions associated with the names of Lwoff, Monod and Jacob came from the Pasteur Institute, an institution not controlled by a university. In the United States the Rockefeller Institute was a major contributor, through the work of Avery, MacLeod and McCarty, to the new developments. It is indeed most remarkable that universities allowed the initiative in advancing the frontiers of knowledge to slip out of their hands in this way.

The loss of leadership in science by the universities is also borne out by statistics of the Nobel awards to British scientists, which are shown in Table 1. Out of 18 British awards since 1950, only 10 laureates have earned their awards when holding university appointments—and at least one of them, myself, had a privileged appointment with very light teaching and administrative duties at the critical time. The statistics become even more telling when they are limited to the more recent times. Since 1960 only three Nobel awards went to the universities in Britain and five to non-university scientists (and this includes the physical sciences). In this table "other centres" means, in every case except one, the Medical Research Council's units. The exception is A. L. Hodgkin at Cambridge who holds a full-time research professorship of the Royal

Society. In comparing these figures one has to bear in mind that the financial resources of the universities are very much greater, as a whole, than those of the Medical Research Council or the Royal Society. The funds at the disposal of the Medical Research Council were rather less than 5 per cent of those available to the universities, and universities employ probably more than 10 times as many scientists as the Medical Research Council. In spite of this handicap the Medical Research Council has a much larger share in the number of Nobel laureates.

Table 1. BRITISH NOBEL AWARDS SINCE 1950

Universities (10)		Other centres (8)	
C. F. Powell	(1950)	A. J. P. Martin	(1952)
J. D. Cockcroft	(1951)	R. L. M. Synge	(1952)
E. T. S. Walton	(1951)	F. Sanger	(1958)
H. A. Krebs	(1953)	F. M. Perutz	(1962)
M. Born	(1954)	J. C. Kendrew	(1962)
C. N. Hinshelwood	(1956)	F. H. C. Crick	(1962)
A. R. Todd	(1957)	M. H. F. Wilkins	(1962)
P. B. Medawar	(1960)	A. L. Hodgkin	(1963)
A. F. Huxley	(1963)		
D. C. Hodgkin	(1964)		

Another illustration of this trend is provided by the statistics of the Fellowship of the Royal Society. Of 32 Fellows elected in March 1967, only 13 did their decisive work in the universities and some of these 13 were again in privileged positions within the university, occupying research posts without teaching commitments.

Why then have the universities lost their leading position in research? I believe the answer is simple. There is plenty of potential talent in British universities to achieve distinction in science; what is lacking is simply time. Real research of a fundamental character requires a tremendous amount of time. It cannot be done at odd spare moments, nor can it be delegated to technicians or PhD students. The trouble is that senior and junior academic staff tend to be grossly overloaded with teaching, administration and college administration—in particular at Oxford. This overloading often begins at a very early stage of the academic career and leaves junior people insufficient time to mature during the postdoctoral stage. What scientists need for maturing are, I think, several postdoctoral years of essentially full-time research before they embark on teaching on a major scale.

### Policies

Another illustration of the importance of time for establishing academic standing is the relatively large number of university professors supplied by Medical Research Council establishments. Between 1961 and 1966, no fewer than 42 Medical Research Council staff went to universities to take up professorial appointments. This was possible because the Medical Research Council provides opportunities that universities cannot provide, giving scientists, above all, enough time. Thus Medical Research Council establishments have proved to be very effective breeding grounds for scientists suitable for senior university posts. I ought to emphasize that it is quite wrong to blame the Medical Research Council (as has been done) for keeping some excellent people away from the universities, when these people, after maturing, return to the universities well prepared for senior appointments.

Research, unlike routine jobs such as teaching or doctoring or administration, needs a minimum critical effort to be effective, and this minimum is very demanding in time. I have often heard it said by those university people who do not know what scientific research means, "Well, if you only have half the amount of time you feel you ought to have, cut down your research by half. What does it matter?"

This reasoning is false. It is like the idea that in order to cut down the noise of an aeroplane engine the speed of the engine should be reduced. Up to a limited point, of

course, this works and the aircraft just travels more slowly. But soon there comes a point when it will no longer remain airborne. At low engine speed it can still taxi along the ground, but that is all.

Scientific research requires a high minimum critical momentum. Effectiveness in research is not just proportional to the effort. The scientist who has insufficient time may manage to taxi along over well ploughed grounds but he will have the greatest difficulty in becoming airborne—doing something really new and original. On the other hand, once he has gathered momentum he will soon find himself in new and unknown territory. One of the most effective ways of attaining a powerful momentum is belonging to a team. Contrary to what some may feel, membership of a team does not at all imply loss of individual scope, of individual initiative, of individual achievement, of individual recognition. What the team provides is a background of aggregate skill, experience and help. This background forms the starting point for individual enterprise.

In the last resort, then, the reason for failing to obtain excellence, in spite of great potentialities, is in many cases the circumstance that those responsible for the organization of the lives of scientists rob them of time.

All this leads to the large question of whether our universities today do as much as they ought to in providing centres of excellence in science, a matter taken for granted a generation ago. In many American universities this is a frequent subject for discussion, and it is perhaps significant that the present United States Secretary for Health, Education and Welfare, John Gardner<sup>11</sup> (formerly President of the Carnegie Foundation for the Advancement of Teaching), has written a provocative book called *Excellence* with the sub-title "Can we be equal and excellent too?". I am not at all sure whether our main financial sponsors, the University Grants Committee and in particular the Treasury, give sufficient thought and

money to the importance of cultivating excellence in the universities; to the fact that in science, teaching and research always go together and that in this age of science the cultivation of excellence in science is not an academic exercise but a source of economic and political strength.

My own apprehensions are naturally influenced by my personal experience at Oxford where, under the banner of equality and democracy, circumstances operate powerfully against the development of excellence in science. In quite a few spheres of the life of this country I fear we have too much equality and too little promotion of excellence. At Oxford very few of the excellent young scientists are given a chance to develop their potentialities in scientific research, merely because they are deprived of the time. A large number of promising and distinguished scientists have for these reasons left Oxford or refused appointments there. This might benefit other British universities if they can show themselves more sympathetic or able to help them, but lack of opportunities, especially in terms of time, has also contributed towards the "brain drain".

Unless we in the universities are aware of these problems and continuously strive for the maintenance of high standards, we are bound to deteriorate. This is a matter of general concern to university people.

## Structure of N-terminal Fragments of Fibrinogen and Specificity of Thrombin

by

B. BLOMBÄCK

M. BLOMBÄCK

B. HESSEL

S. IWANAGA

Department of Blood Coagulation Research,  
Karolinska Institutet, Stockholm

Determination of the amino-acid sequences of N-terminal fragments from human fibrinogen A and B chains shows that this region of the molecule is highly cross-linked with disulphide bridges and suggests why the proteolytic action of thrombin is so highly specific.

THE fibrinogen molecule is built up from three peptide chains, A, B and C (refs. 1-9). The molecular weight of 340,000 determined for the protein<sup>10</sup> is for a dimeric form of the molecule. The formation of fibrin threads is preceded by a limited proteolysis of the fibrinogen molecule, resulting in the release of fibrinopeptides A and B, respectively, from the N-terminal end of the A- and B-chain of fibrinogen<sup>11-14</sup>. The enzyme causing this limited proteolysis is thrombin. In its proteolytic action on fibrinogen thrombin has a narrow specificity of action. On synthetic substrates of low molecular weight, on the other hand, its action closely resembles trypsin; for example, it cleaves compounds like tosylarginine methyl ester<sup>15</sup>. When acting on fibrinogen only a few bonds are rapidly hydrolysed. These are the arginyl-glycine bonds linking the

fibrinopeptides to the rest of the fibrinogen molecule. Some other arginyl and possibly also lysyl bonds in fibrinogen may be split by the enzyme, but apparently at a much slower rate (compare ref. 16).

It has been suggested that the fibrinopeptides might contain structural features which are partially responsible for the narrow specificity of the enzyme<sup>8,16-20</sup>. Structures which might favour a rapid association between enzyme or substrate (or possibly activate the enzyme) are present in the C-terminal part of fibrinopeptide A (refs. 16, 17 and 20). This idea has mainly arisen from the fact that the C-terminal part of fibrinopeptide A has been essentially unchanged during mammalian evolution. Furthermore, it has been shown that fibrinopeptides inhibit thrombin action<sup>13,17</sup>. It should also be mentioned that when cross-

Fig. 1. Elution pattern of fibrinogen treated with cyanogenbromide on 'Sephadex' before (a) and after reduction and alkylation (b). Column: 'Sephadex G-100', 20-28 cm<sup>2</sup> × 66-70 cm. Flow rate: 60 ml./h. Equilibration and elution with 10 per cent acetic acid in a and 10 per cent acetic acid containing 5 per cent ethanol in b. The dashed part of the chromatogram shows the main fraction which on incubation with thrombin released fibrinopeptide A. Small amounts of this peptide were also released from fractions 1 and 3. (The conditions for digestion were: 1 per cent peptide in 0.2 molar ammonium bicarbonate, pH 8.5, 17-35 NIH units/ml., 37° C, 1 h.)

reacting thrombin and fibrinogen from several mammalian species, thrombins from different species show remarkably small differences in their clotting action on fibrinogen from one species (ref. 21 and unpublished observations of A.-C. Teger-Nilsson).

The release of fibrinopeptide A from fibrinogen seems to be a *sine qua non* for the polymerization of fibrinogen units. In all the species so far investigated the release of the B-peptide is slower than that of the A-peptide and its release appears to be of no importance at least in the initial polymerization (compare ref. 16). Comparative studies show that the B-peptide has been subjected to more changes than the A-peptide during evolution<sup>18,20</sup>.

Thus there is some evidence that in the clotting process the interaction of thrombin is determined mainly by structures in the fibrinopeptides; however, in any discussion of thrombin action it would be injudicious not to take into consideration the adjacent structures on the other side of the bonds split, let alone the complex conformation of the whole fibrinogen molecule. In the present report the amino-acid sequences around the bonds split by thrombin in human fibrinogen and their implications are discussed.

A preliminary step in the study was the isolation of N-terminal fragments of the A-chain and B-chain of fibrinogen containing the covalently linked fibrinopeptides A and B.

A fragment containing fibrinopeptide A can be isolated, after digestion of sulphitolyzed fibrinogen with plasmin, by gel-filtration, column chromatography and electrophoresis<sup>22</sup>. The fragment is composed of 43 amino-acid residues. Thus it contains 27 amino-acid residues in addition to the 16 in the A-peptide. This plasminic fragment does not contain methionine. Thus it should be possible to obtain a still longer N-terminal fragment of the A-chain by treating fibrinogen with cyanogen bromide (CNBr)<sup>23</sup>. Such a fragment was in fact produced by cleavage of native fibrinogen dissolved in 70 per cent formic acid<sup>24</sup> with cyanogen bromide. The reaction products were partially separated on a 'Sephadex G-100' column equilibrated with 10 per cent acetic acid (Fig. 1a). Fraction 2, which on treatment with thrombin released both fibrinopeptide A and B, was reduced with mercaptoethanol and afterwards alkylated with iodoacetic acid<sup>25</sup>. Excess reagent was removed by gel filtration ('Sephadex G-10' equilibrated with 10 per cent acetic acid). The S-carboxymethyl peptides were again fractionated on 'Sephadex G-100' equilibrated with 10 per cent acetic acid containing 5 per cent ethanol (Fig. 1b). Fractions 5 and 6 (Fig. 1b) were the only fractions which released appreciable amounts of fibrinopeptide A on digestion with thrombin. These fractions could be further purified by re-cycling gel

filtration<sup>26</sup> on 'Sephadex G-100', or by partition chromatography on propoxy-'Sephadex'. Amino-acid analyses indicate that the purified peptide preparation, 'mother peptide A', contains 50 amino-acid residues (Table 1). It is seven amino-acids longer than the fragment obtained from a plasminic digest. The small amounts of threonine and isoleucine (see Table 1) are most likely derived from a contaminating peptide which has so far proved extremely difficult to separate from the main peptide.

Fig. 2. Two-dimensional electrophoresis chromatography<sup>27</sup> of the valyl-peptide, T2 (see Table 1). High voltage electrophoresis was run in pyridine : glacial acetic acid : water (100 : 35 : 4,865, v/v), pH 5.5 at 2,000 V, 55 m.amp, for 2.5 h in a horizontal apparatus (AB Analysteknik, Valentuna, Sweden) cooled with tap water. Descending chromatography in n-butanol : pyridine : glacial acetic acid : water (150 : 100 : 30 : 120, v/v) at 20° C for about 12 h. The peptides were stained with ninhydrin. y, Yellow spot.

Alanine was found to be the predominant N-terminal amino-acid of mother peptide A, but there were also traces of aspartic acid and asparagine. The amino-acid sequence of the first nine residues from the N-terminal end of this material, determined by the Edman (compare ref. 8) procedure, was identical to that of human fibrinopeptide A. Hence we concluded that the mother peptide A was mainly derived from the N-terminal end of the fibrinogen-A chain.

The peptide preparation was susceptible to the action of thrombin; fibrinopeptide A (ref. 8) was released on incubation with the enzyme (0.4 per cent peptide in 0.15 molar ammonium bicarbonate, adjusted to pH 8.5 with solid CO<sub>2</sub>, was digested with thrombin (350 NIH\* units/

\* National Institutes of Health.

mg) at a concentration of 78 NIH units/ml., for 3–4 h at 37°C. In addition to fibrinopeptide A its analogues fibrinopeptide AP and Y (ref. 8) were released. The presence of small amounts of fibrinopeptide Y in the material explains the occurrence of traces of N-terminal aspartic acid found in addition to the main N-terminal alanine. From these results we concluded that the peptide preparation essentially consists of the N-terminal ends of the A-, AP- and Y-chains of human fibrinogen.

Electrophoresis and N-terminal analysis of the thrombin digest of mother peptide A revealed that thrombin had produced two other fragments in addition to fibrinopeptide A and its analogues. One was a basic tripeptide (T1) (Table 1) with the sequence Gly-Pro-Arg and the other a peptide (T2) containing 31 amino-acid residues (Table 1) having the following partial sequence: Val-Val-Glu-Arg-His-GIN-Ser-Ala-Cys-Lys-Asp-Ser-Asp-. These peptides were isolated from the digest by means of gel filtration on 'Sephadex G-50'. The tripeptide (T1) was separated from the fibrinopeptides by high voltage electrophoresis at pH 4.1.

Table 1. AMINO-ACID COMPOSITION OF N-TERMINAL PEPTIDE ("MOTHER PEPTIDE A") OF A-CHAIN OF FIBRINOGEN AND DIFFERENT FRAGMENTS OF IT

Total residues	50	3	31	14	6

The amino-acid analysis was performed with a Technicon 'Auto Analyser'. The hydrolysis was performed in 5.7 normal HCl at 110°C. The mother peptide and T-2 were hydrolysed for 22 and 48 h; the other peptides only for 22 h. The most probable number of residues is indicated within parentheses.

\* Determined as sum of S-carboxymethyl cysteine and cystine.

† Extrapolated value.

‡ Methionine was recovered as homoserine. This peak appeared in front of glutamic acid and was sometimes not completely separated from this amino-acid.

§ This peak, apparently derived from glutamic acid, was observed in front of glycine. In some runs, it could not be separated from glycine. The colour yield has been assumed to be the same as for norleucine.

In order to align the two fragments, T1 and T2, we treated fibrinogen with thrombin, thus releasing fibrinopeptide A and B, yielding fibrin. We then isolated the N-terminal fragments of the A-chain of the fibrin. To do this the fibrin was dissolved in 70 per cent formic acid, treated with CNBr and the reaction products separated on 'Sephadex G-100'. An elution pattern similar to that shown in Fig. 1a was obtained. The fraction with the same elution volume as fraction 2 (Fig. 1a) was pooled, mercaptolysed and alkylated. After S-carboxymethylation the fractionation on 'Sephadex G-100' was repeated. The elution pattern was essentially the same as that shown in Fig. 1b. The fraction corresponding to fractions 5 and 6 (Fig. 1b) was pooled. This peptide preparation had glycine as N-terminal amino-acid and the following partial sequence: Gly-Pro-Arg-Val-Val-. These results show that the tripeptide Gly-Pro-Arg (T1) succeeds fibrinopeptide A (or analogues) and precedes fragment T2 in mother peptide A.

To obtain more information on the amino-acid sequence of the C-terminal part of the mother peptide A, the so-called valyl peptide (T2) was digested with trypsin<sup>27</sup> (weight ratio enzyme: substrate, 1:100) at pH 8.5 (0.2 molar ammonium bicarbonate adjusted with solid CO<sub>2</sub>) for

3–4 h at 37°C. The five principal tryptic peptides (Try 1–5), revealed on a "finger-print" (Fig. 2), were isolated by gel filtration ('Sephadex G-25' in 10 per cent acetic acid) and paper electrophoresis at pH 3.5–5.5. Try 3 was shown to be identical with homoserine and must thus be C-terminal in the valyl peptide (T2). Try 4 was a tetrapeptide with the sequence: Val-Val-Glu-Arg. Try 5 was a hexapeptide with the sequence: His\*-GIN-Ser-Ala-Cys†-Lys. Try 2 was a hexapeptide (Table 1) with the sequence: Cys-Pro-Ser-Gly-Cys-Arg. Try 1 was a peptide containing 14 amino-acid residues (Table 1) with the following partial sequence: Asp-Ser-Asp-Trp-Pro-Phe-. It was the only peptide on the finger-print that gave a positive reaction with reagents that stain tryptophan. Analysis<sup>28</sup> of the whole mother peptide A indicated that it contains two tryptophan residues. Both of these must be in Try 1 since neither the fibrinopeptide A nor the other tryptic peptides (2–5) from mother peptide A contain tryptophan. From all the above analyses the partial sequence for the mother peptide A could be deduced (Fig. 3). The sequence seems the same for 43 amino-acid residues from the N-terminal end for both the plasmic fragment<sup>22</sup> and that produced by CNBr.

Fig. 3. Amino-acid sequence of the N-terminal part of the A-chain of human fibrinogen. The cleavage site by thrombin (T), trypsin (Try), plasmin (PL) and cyanogen bromide (CNBr) is indicated by arrows. Amino-acid residues within brackets are deduced from the amino-acid analysis of the acid hydrolysate of Try 1 (compare Table 1). The AP peptide is phosphorylated at residue No. 3.

The amino-acid sequence of the N-terminal fragment of the A-chain presents some interesting features. The first half-cystine residue is at position 28 (Fig. 3). From there on to the C-terminal end of the "mother peptide A" there are three more half-cystine residues. Altogether 14 per cent of the half-cystine residues of the whole fibrinogen molecule<sup>29</sup> are located in the N-terminal peptide which constitutes only about 3 per cent of the fibrinogen molecule. Because no free SH-groups have been demonstrated in fibrinogen<sup>30</sup> these half-cystine residues must take part in the formation of disulphide bridges. If all the disulphide bridges are interchain it would mean that about 30 per cent of the half-cystine residues of fibrinogen are linked together with the N-terminal part of the A-chain. This area of the molecule in any case forms a dense "disulphide knot". We have so far no definite information on which parts of

\* In the first cycle of the Edman procedure PTH-histidine together with small amounts of PTH-glutamine were found. The appearance of a succeeding amino-acid residue in a sequence during a degradation cycle where histidine is involved has also been noted for some other peptides (unpublished observations of Blomback). The cleavage of the chain, under the conditions used, apparently takes place during the coupling with phenylisocyanate at pH 9–9.5.

† Identified as the PTH-derivative of S-carboxymethyl cysteine.

the molecule are joined by disulphide bridges. However, the action of CNBr on fibrinogen suggests that the N-terminal part of the B- and C-chains might be joined to the N-terminal region of the A-chain. After splitting the molecule with CNBr and fractionating the mixture on 'Sephadex G-100', the disulphide containing fraction 2 (Fig. 1a) contains the N-terminal parts of both the A-chain and the B-chain. It also contains the N-terminal part of the C-chain. (Note added in proof. This fragment has the following partial N-terminal sequence: Tyr-Val-Ala-Thr.) The fibrinopeptide A portion of the molecule is probably not involved in the "disulphide knot". Its overall hydrophilic nature makes it likely that it is on the surface of the molecule.

We have also isolated the N-terminal fragments of the B-chain containing covalently linked fibrinopeptide B from both plasmic digests of sulphitylated fibrinogen<sup>22</sup> and cyanogen bromide treated native fibrinogen. These were referred to as plasmic mother peptide B and CNBr mother peptide B. The CNBr mother peptide B, fraction 3 (Fig. 1b), released fibrinopeptide B on incubation with thrombin. After alkylation this fraction was partially purified by gel filtration on 'Sephadex G-75' in 10 per cent acetic acid and subsequently on 'Sephadex G-100' in the same medium. The purified S-carboxymethylated CNBr mother peptide B is much longer than the corresponding fragment obtained from a plasmic digest<sup>22</sup> which contains only 21 amino-acid residues. Phenylisothiocyanate fails to react with the CNBr mother peptide B and after digestion with thrombin and low voltage electrophoresis at pH 6.4 it yields two main and four minor fractions. One of the main fractions has the same electrophoretic mobility at pH 6.4 as fibrinopeptide B (ref. 8) and is furthermore ninhydrin negative but Sakaguchi positive. The other main fragment has the following partial amino-acid sequence: Gly-His-Arg-Pro-Leu-Asp-. This sequence is identical with the sequence of six amino-acid residues, from the N-terminal end, of the C-terminal heptapeptide obtained after digestion of the plasmic mother peptide B with thrombin<sup>22</sup>. From these results the N-terminal sequence of the first 20 amino-acid residues at the N-terminal end of the B-chain of fibrinogen was deduced (Fig. 4). The minor thrombinic fractions have not been analysed further.

Fig. 4. Amino-acid sequence of the N-terminal part of the B-chain of human fibrinogen. The arrow indicates the cleavage site by thrombin.

On treatment of the CNBr mother peptide B with trypsin about ten fragments could be demonstrated on a finger-print<sup>27</sup> but, except for fibrinopeptide B, they have not yet been characterized.

These results give some clues regarding the requirements of thrombin action. The difference in rate of cleavage of the A-fibrinopeptide arginyl bond in fibrinogen and of other arginyl or lysyl bonds in fibrinogen or other proteins is to some extent a matter of "accessibility". One would expect that unfolding the substrate would increase the number of bonds split. When the N-terminal fragment produced by cleavage of the molecule with CNBr is digested with thrombin the tripeptide, Gly-Pro-Arg, is released in addition to fibrinopeptide A. If native fibrin, which is resistant to the further action of thrombin, is treated with CNBr and then digested with thrombin the same tripeptide is released, which means that the No. 19 arginyl bond (Fig. 3) in the A-chain of fibrinogen and the corresponding bond in fibrin have both become available for the acylation reaction with thrombin. Thrombin also seems to split additional bonds in the CNBr mother peptide B. These experiments certainly show that the cleavage by the enzyme can be influenced by modifying the substrate. The number of arginyl or lysyl bonds

that are hydrolysed in the protein treated with CNBr, however, is still very low. Reduction and alkylation of the treated protein do not change the situation appreciably. This means that, although thrombin has a trypsin like specificity of action on acylated arginyl and lysyl esters (compare ref. 16), only a few of the about 100-150 trypsin susceptible bonds in fibrinogen and fibrin (per 170,000 unit molecular weight) are accessible to the enzyme even after cleavage of all methionyl and S-S bonds in the molecule.

We are apparently dealing with an enzyme with an extraordinary hidden active centre which for steric reasons can react easily only with the N-terminal parts of the A- and B-chain of fibrinogen and fibrin, even when the protein presumably has been unfolded to a high degree. One might speculate that the location of a proline residue in close vicinity to the vulnerable arginyl bond in both the A and B N-terminal fragments (Figs. 3 and 4) creates a sterically more suitable structure for the active centre of the enzyme.

In order to explain the differences in susceptibility of the different arginyl and lysyl bonds in fibrinogen and fibrin towards thrombin we have to consider not only steric factors but also specific interaction. The extremely rapid release of the A-fibrinopeptide during the clotting process, its great stability during mammalian evolution and the facts presented in this report reinforce our previous suggestion (compare refs. 16 and 20) that specific structures in the A-fibrinopeptide or its immediate surroundings favour an "opening up" of the active centre of the enzyme or a firm association between enzyme and substrate. Thorough kinetic analysis of thrombin action on the N-terminal fragments of the A- and B-chain of fibrinogen or fibrin and on derivatives of them would certainly shed more light on this question.

The experiments reported in this paper were supported by grants from the US National Institutes of Health, Bethesda, and the Swedish Medical Research Council. We thank Mrs Sonja Söderman, Mrs Helga Messel, Mrs Anita Lindholm, Mr Jan Reuterby and Mr N. J. Gröndahl for valuable technical assistance.

# Fractionation of Iron in the Solar System

by

P. G. HARRIS

Department of Earth Sciences,  
University of Leeds

D. C. TOZER

School of Physics,  
University of Newcastle upon Tyne

In the preplanetary dust cloud, particle adhesion and aggregation would have been most effective for magnetic grains. Enrichment of iron in the region of the inner planets could have occurred by a particle-size fractionation, the outward dispersal of small, metal-poor aggregates leaving behind only the larger aggregates enriched in magnetic particles of iron.

CURRENT theories on the formation of the solar planetary system<sup>1-3</sup> have met with some success in accounting for its present dynamical properties, but there is still great uncertainty about the processes that have led to the measured densities of the planets<sup>4-6</sup> (Table 1). Different degrees of phase transformation seem inadequate to account for the density differences, which are consequently attributed to chemical differences. Any unitary theory of formation of the solar system must therefore account for chemical fractionation either in the preplanetary solar nebula or at some subsequent stage. Adequate theories exist as to why some of the lightest elements, which are gaseous or have gaseous compounds, are depleted in the inner planets relative to their solar abundances, but, as Urey<sup>7</sup> emphasizes, it is much more difficult to explain any differences in the relative abundances of the non-volatile elements of medium or heavy atomic weight, either among the inner planets or between these planets and the Sun.

Table 1. DENSITIES OF THE INNER PLANETS

Planet	Mass*	Density g/cm <sup>3</sup>	Wt. per cent of metal phase†
Mercury	0.054	5.33	63
Venus	0.81	5.15	26
Earth	1.00	5.52	32
(Moon)	0.012	3.33	5
Mars	0.11	4.00	19
Asteroids ‡ per cent	10 <sup>-4</sup>	3.5	0-30

\* Expressed relative to the Earth.

† Calculated by assuming that the various bodies are effectively two phase systems of densities 3.3 g/cm<sup>3</sup> and 7.9 g/cm<sup>3</sup> (recalculated to mean density of 10 kbars).

‡ Density and metal content of asteroids are based on the values for chondrites.

All values taken from Ringwood<sup>6</sup>. The values of Urey<sup>7</sup> differ slightly.

Perhaps the most significant evidence comes from analyses of meteoritic material and the solar atmosphere. In a general discussion of the chemical analyses of chondritic meteorites (in particular, Type 1 carbonaceous chondrites) and the spectral analysis of the solar atmosphere, Urey<sup>7,8</sup> suggests that abundance differences are quite well established at least for iron and some other elements of the iron group. If carbonaceous chondrites (or any other chondrite) are assumed to be average samples of primitive asteroidal material, some chemical fractionation process has increased by a factor of 3 or 4 the iron content relative to an average for non-volatile light elements, of planetary material at that general solar distance.

The evidence for important chemical differences among the inner planets is based on an interpretation of their mean densities. A unique solution is impossible with present data, but one treatment of the problem is to assume that inner planets are composed of different proportions of metal and silicate corresponding to terrestrial core and mantle material (Table 1, after Ringwood<sup>6</sup>). The comparison of the iron content or of the iron to

silicon ratio of inner planets such as the Earth, with solar or meteoritic material, then rests on assumptions about the composition of the terrestrial core and mantle. For example, Urey<sup>7,8</sup> assumes that the core material in each planet is essentially of the same composition as the metal phase in most meteorites, that is an iron-nickel alloy, and because the planets differ from one another in density and metal content, they differ also in overall chemistry, as shown by the iron to silicon ratios of Table 2. On the other hand, Ringwood<sup>6</sup> considers that the inner planets have the same content of involatile elements (and the same iron to silicon ratio) as chondritic and solar material, and originally consisted of material of the composition of carbonaceous chondrites. During and after formation of the planets, they suffered varying degrees of auto reduction to give rise to their present ratios of free metal to silicate.

Table 2. ATOMIC IRON-SILICON RATIOS

Body	Iron-silicon ratio
Sun	0.2
Mercury	~3.0
Venus	~1.0
Earth	1.0
(Moon)	0.3
Mars	0.6
Chondrites*	0.7
Carb. chondrites (type 1)	0.9

\* Mean of low and high iron chondrites.

All values taken from Urey<sup>8</sup>.

The purpose of the present article is to describe qualitatively how a degree of the chemical inhomogeneity inferred by Urey may have been achieved at the preplanetary stage during cooling of the solar nebula. An examination of Table 2 shows that the degree of iron enrichment found by Urey<sup>7,8</sup> decreases fairly regularly with increasing distance from the Sun, and that all the terrestrial planets and chondrites have a greater iron enrichment than the solar atmosphere. Accepting that planets have been created from material left behind at the equator of a contracting, rotating solar nebula<sup>1-3</sup>, either non-ferrous material has been preferentially lost outward from orbits near the Sun, or iron has been brought inward from greater distance to these orbits. This article suggests the preferential loss of iron-poor material and the retention of iron-enriched material in the region of the inner planets by a process of particle-size fractionation.

We shall try to trace the chemical history of iron in the nebular material. We shall assume that the discarded material had a chemical composition closely similar to the present Sun. During rapid cooling from an initial ejection temperature of 1,000-2,000° K, there would have been a continuous adjustment of chemical equilibrium between involatile compounds present as a dust and the residual gas. At temperatures above 1,000° K and in the presence

of hydrogen and water in cosmic molecular proportions (500:1) the reaction;

would have been well to the right. From the calculations of Urey<sup>10</sup> and Latimer<sup>11</sup>, modified by Mueller<sup>12</sup> to allow for the activity of  $\text{Fe}^{2+}$  in solid solution, the iron would have been virtually all in the metal phase, with  $\text{Fe}^{2+}$  in only 1 per cent of the cation positions in ferromagnesian silicates at 750° C. At about 300° C, enough iron would have become oxidized to occupy 20 per cent of the cation positions, and at 100–200° C oxidation would have been virtually complete.

The size of particles formed by direct condensation from the gas phase is very uncertain. Arguing by analogy, chemical smokes on formation often have particle size of  $10^{-4}$  to  $10^{-5}$  cm;  $10^{-5}$  cm is also quoted for the size of cosmic dust, and, according to Wood<sup>13</sup>, the groundmass of carbonaceous chondrites appears to contain particles of  $10^{-4}$  to  $10^{-6}$  cm. Dynamical arguments suggest that there must have been growth in the particle size of the matter which is now the inner planets, to some minimum size, while its mean free path was much smaller than the cloud, and the electromagnetic radiation in the cloud approximately isotropic. Otherwise it would have been rapidly dispersed by radiation pressure and perhaps a solar wind. For the present solar luminosity this critical size is about  $10^{-4}$  cm and we shall at first assume this as the primary particle size. It can be shown that if the present mass of the inner planets was distributed as such particles within the present Martian orbit, the mean free path based on interparticle collisions is at most only  $10^8$  cm. With such a small mean free path, the collision velocity distribution of the dust particles will be determined by the residual particle velocities, after the local streaming velocity needed to balance solar gravitational attraction by centrifugal force is subtracted. Turbulent motions will probably not significantly affect the calculations given later. If allowance is made for the presence in the cloud of hydrogen in solar proportions, it may be demonstrated that it is reasonable to regard the dust particles as being in complete thermal equilibrium with the gas. In this case, the mean dust-particle velocity is about 0.1 cm/sec for  $10^{-4}$  cm particles at 1,000° K, and the mean collision velocity is twice this for a Maxwell distributed system.

In the earliest stages before self-gravitation becomes significant, the aggregation of the primary dust particles will be by mechanisms of adhesion. In the presence of hydrogen in solar proportions the gas pressure could be as high as  $10^{-1}$  atmospheres so that the adhesion by chemical bonding observed under ultra-high vacuum will not occur<sup>14</sup>. A much weaker load-independent adhesion is found in the presence of gases, which is attributed to dispersion forces. Surface films and electrostatic forces can also contribute to adhesion, but with the exception of electrostatic forces they are all of extremely short range and could never give capture or "sticking" cross sections significantly greater than the optical cross section—probably much less. Ambient conditions do not favour electrostatic charging and it is a moot point whether an electrostatically enhanced collision cross section would lead to a correspondingly enhanced capture cross section; charge sharing would occur on contact and the resulting electrostatic repulsion might reduce the chance of adhesion by an even larger factor. This seems a point worth experimental check.

We would like to suggest that an interesting long range interaction that can lead to enhanced capture or "sticking" cross sections is the magnetostatic attraction of ferromagnetic dust particles. It will be seen that with a Curie point for iron or iron-nickel alloy of more than 700° C and an average time interval between dust particle collisions based purely on the optical cross section, of the order of one year, there would have been time for a very large number of such collisions before oxidation of the

iron occurred to any significant degree. The calculation of capture cross sections for this interaction is somewhat involved and we give an outline of our method of estimation.

Despite the fact that one can adequately treat the dust collisions as two body interactions, ignoring damping effects introduced by residual gas, the general problem of computing orbital motion resulting from magnetic interaction is extremely difficult. The magnetization of the primary particles, even if they were as large as  $10^{-3}$  cm, would be of uniform single domain type and, in general, effectively fixed by shape and crystalline anisotropy with respect to the axes of the inertia tensor. A full discussion of the motion in this case of non-central forces is impractical and one must be content with a demonstration of the enhancement of capture, accurate to within perhaps a factor of five, based on a central force approximation.

Because we are interested only in the possibility of the interaction leading to greatly enhanced capture it is permissible to neglect all except the dipole moments  $M_1$  and  $M_2$  of the particles. The use of the central force approximation with reduced mass  $\mu$  in this situation is equivalent to assuming that the relative orientation of the dipoles is fixed in the collinear position and we shall assume that this is such as to minimize the potential energy of the system. A necessary condition for this to be valid is that the period of oscillations of one particle in the magnetic field of the other is smaller than the time for the radius vector to describe an angle of  $2\pi$ . The absence of any consideration of the process by which the requisite collinearity of the moments is attained at great distances may be responsible for an overestimation of the capture cross section by a factor of two or three. The potential energy is

$$-\frac{2 M_1 M_2}{r^3}$$

and it is well known that with such rapidly varying potentials, orbits are either open or involve spiralling to the centre of force if the impact parameter is less than a certain value<sup>15</sup>. It may be shown that the cross section for spiralling, which we identify with the capture cross section, is given by

$$\sigma = 3\pi \left( \frac{2 M_1 M_2}{\mu V_\infty^2} \right)^{\frac{2}{3}}$$

where  $V_\infty$  is the velocity at infinite separation. Putting the particle volumes both equal to  $V$  and an intensity of magnetization  $I$ , we have

$$\mu = m/2$$

$$V_\infty^2 = 2 V^2 = \frac{6 kT}{m}$$

and substitution gives

$$\sigma = 3\pi \left( \frac{2 V^2 I^2}{3 kT} \right)^{\frac{2}{3}}$$

For the thermalized dust particles envisaged here with the magnetization  $I$  of about 200 E.M.U. (a value that would be attained about 50° C below the Curie point of about 1,000° K) we obtain  $\sigma = 1.2 \times 10^{-4}$  cm<sup>2</sup>. This is about  $2 \cdot 10^4$  times the optical cross section. At a separation of 100 particle diameters, the magnetic field resulting from each moment is about  $10^{-3}$  gauss and a general ambient field large enough to affect the capture probabilities seems unlikely. Further investigation indicates that for these particles the ratio of the instantaneous orbital period at the critical impact parameter distance of order  $\sqrt{\sigma}$ , to the period of small oscillations of a particle in the field of the other is approximately 70 and decreases to about 10 at the instant of contact. This seems to justify the use of the central force approximation in this case.

More general consideration indicates that this ratio of periods is proportional to  $(V I^2)^{\frac{1}{3}}$  while the ratio of capture

to optical cross sections for a thermalized dust cloud varies as  $(V^2)^{-1/2}$ . From this we may conclude that because the intensity of magnetization is limited to less than about five times the value chosen previously, enhancement of aggregation by magnetic attraction is negligible for particles much smaller than  $10^{-5}$  cm.

The efficiency of magnetic capture for the resulting aggregates probably declines as the number of primary particles forming them increases. Only if the particles were added with random moments and the bodies retained thermal velocities would the ratio of capture and optical cross sections remain unchanged. In practice there will be definite cancellation of moments that will lead to a decline in this ratio as  $N^{-1/2}$ , where  $N$  is the number of particles per body; if the particles do not remain thermalized and collision velocities are fixed by the terminal velocity in the gas, it falls as roughly  $N^{-2}$ . For a thermalized cloud of  $10^{-4}$  cm particles, the aggregations would grow most rapidly to about  $10^3$  particles and thereafter optical and capture cross sections would be virtually identical. This could still be a much greater capture cross section than for silicate dust of comparable optical size.

Let us now examine how these results might be used to explain the large scale chemical inhomogeneity referred to previously. At high temperatures in a thermalized dust cloud, the cross sections for adhesion are probably extremely small compared with the optical cross section and all primary dust particles might well survive as independent bodies down to the Curie temperature. Thereafter the cross section for mutual capture of the metallic particles grows by an enormous factor for only a further fall in temperature of a few tens of degrees Celsius. The magnetic metallic dust would rapidly be collected into aggregates of at least several thousand particles in a time of the order of years. The further evolution of the system will depend on the relative timing of the cooling and the escape of residual gas. The degree of oxidation of the aggregates, which might also act as a cementing process, will be dependent on the pressure of residual gas left below  $300^\circ\text{C}$ .

The outward removal of the gas as from the region of the inner planets would be accompanied by a particle size sorting<sup>16</sup>, the finer particles being carried away with the gases. Also when the residual gas was removed, the remaining particles would have been subjected to the full

effect of radiation pressure and solar wind. All these factors would have resulted in the outward removal of the smaller particles and aggregates, and a preferential retention of the larger aggregates. It is reasonable to suppose that aggregates large enough to avoid expulsion from the vicinity of the Sun were iron-enriched, and hence the iron to silicon ratio in the inner planets became higher than the solar value. There would be a progressive decrease outwards, in iron content, among the inner planets and asteroids. Each planet would have a distinctive chemical composition, so that solar and meteorite compositions could not be quantitatively applied to the Earth, in the comparison of elements that are likely to have undergone pre-planetary fractionation.

This mechanism could have caused some fractionation of nickel and cobalt together with iron; comparison of chondritic and solar abundances indicates that this did not occur. An explanation may lie in the possible volatility of these elements in a reducing atmosphere containing carbonaceous and nitrogenous compounds, and in the role of supersaturation during condensation of planetary material<sup>17</sup>. In any case, the recognition of a very specific aggregation mechanism may help to narrow the range of plausible physical conditions during the pre-planetary stage of the solar system.

We would like to thank Professor H. C. Urey for his comments and a preprint of his paper, and Drs R. S. Bradley, E. Irving and J. A. Wood for helpful discussions.

## Geochronology of the St Helena Volcanoes

by

I. BAKER

Department of Geology,  
Imperial College, London

N. H. GALE

J. SIMONS

Department of Geology and Mineralogy,  
University of Oxford

Recent theories of crustal spreading propose that the volcanic islands of the Atlantic have drifted away from the mid-ocean ridge. Do these theories stand up to a close geochronological scrutiny of some of the islands in question?

THERE has been considerable recent interest in the idea that there is a correlation between the ages of oceanic volcanic islands and their nearest distance from a mid-ocean ridge. It has been suggested that such a correlation lends support to the hypothesis of the spreading apart of ocean floors, and thus to the hypothesis of continental drift<sup>1-3</sup>. There has also been recent interest in the possi-

bility of using radiometric ages to investigate the life history of volcanic islands<sup>4-11</sup>. In both cases there are at present only rather scanty quantitative data available<sup>4-12</sup>. It is our object to add to the data by presenting the results of a stratigraphically controlled geochronological study of the island of St Helena using the potassium/argon method.

The volcanic island of St Helena lies in the South Atlantic ocean at longitude  $5^{\circ} 40' \text{ W.}$  and latitude  $16^{\circ} 00' \text{ S.}$ , more than 800 km east of the crest of the Mid-Atlantic Ridge. The island is elongated in a north-east/south-west direction, with maximum linear dimensions of approximately 16.1 km and 9.7 km and an area of about 120 km<sup>2</sup>. St Helena rises through 4,400 m of water to an overall height of about 5,220 m above the ocean floor. The relief of the island is very rugged, and all levels of the sub-aerial volcanoes are exposed as a result of the severe erosion. All the rocks exposed on the island belong to the alkali olivine basalt-trachyte-phonolite assemblage.

The island is formed by the coalescence of two broad basaltic shield volcanoes (Fig. 1). The smaller north-eastern volcano is in part buried beneath the flanks of the main volcano. Eruptions from a third, minor, centre have resulted in extensive flooding of both volcanoes in the east and north-east of the island. The eruptions have occurred predominantly through fissures and pronounced dyke concentrations occur in the central areas of both volcanoes. A number of highly alkaline dykes and parasitic masses intrude the central regions and upper flanks of the south-western shield.

Because the exposures are good in the arid low central regions of the main volcano, it has been possible to establish an accurate stratigraphic sequence. The

younger lavas frequently occur as erosional relics in the thickly vegetated high parts of the island, however, and it has proved very difficult in several cases to determine their relative ages by their field relationships. In the deeply eroded central areas it is impossible stratigraphically to correlate the alkaline intrusive rocks directly with each other or with younger flow groups.

Twenty-four rocks were eventually selected for radiometric dating; of these about half were from stratigraphic levels which could be accurately correlated relative to each other. The others were mainly late intrusive rocks and relic flows of less certain relative ages.

The structure of the smaller volcano is less complex than that of the south-western shield. The oldest rocks—very highly altered breccias of uncertain origin—are exposed as screens between swarms of dykes in the central region. In the dominant sub-aerial flows and pyroclastics of the shield only one major erosional break is seen, separating a very late minor sequence of basaltic agglomerates and thin flows from the main sequence. The western and southern flanks of this volcano are buried beneath flows from the south-west, but one small erosional "window" is exposed in the valley at Jamestown (Fig. 1). Only three rocks from this volcano have been dated: two flows from stratigraphically low (679) and high (145) levels in the sequence, and a dyke (678) known to cut the lower flows (679) in the central region (Fig. 2).

Fig. 1. Major stratigraphic divisions of the St Helena volcanoes. U, Late lavas of the third centre; dotted areas, late trachytic flows and equivalent extrusives; heavy stippled areas and black, alkaline intrusive rocks.

The structure of the south-western volcano is very complex. The centre of volcanic activity has moved at frequent intervals, and at low levels in the volcano extensive pyroclastic deposits, frequently from local cinder cone concentrations, are interstratified with well defined groups of lavas. The positions of the dated rocks are shown in Fig. 2, which is based on the relative ages of the various units as determined from field evidence.

Only one group of altered flows underlies the oldest dated thick group of lavas (785). Overlying these are largely altered pyroclastics and flows, up to 500 m thick locally and divisible into several distinct groups. The sequence forming the lower shield is highly complex, and late activity resulted in the extrusion of a number of thick trachybasaltic flows (792) over an erosional surface cut into several groups of the sequence.

Above these early groups extensive lava flows become dominant and form the main part of the shield. Several distinct groups of flows are apparent, with minor unconformities throughout the pile. Specimens 179 and 78 are from two of these flow groups separated by about 500 m of basaltic and trachybasaltic flows. It is these major shield forming flows which overlap and bury the western and southern flanks of the north-eastern volcano.

The flanks of the volcanoes were extensively eroded during a prolonged period of quiescence. In the east of the island a broad, deep depression was eroded through flows of both volcanoes in the area of their overlap (Fig. 1). Activity subsequently recommenced at a third, minor centre on the flanks of the main shield and lava infilled the erosional depression and other smaller valleys. These late flows may be divided into two groups, an older thick sequence of basaltic lavas (803, and probably 794),

and a younger group of intermediate lavas (TC). The two groups are separated by another marked erosional surface. The trachytic flow domes (105, 111) in the east of the island (Fig. 1) are known from field evidence to be younger than the 803 group of flows and may also be younger than the later TC group.

In the central high ground of the island relic patches of a thick porphyritic olivine basalt (844) are preserved. Although apparently associated with the two late flow groups of the third centre, the isolated nature of the exposures makes it impossible to assess its true stratigraphic position.

The main basaltic shield is intruded by a large number of highly alkaline dykes and parasitic masses. Several of the individual bodies (88, 121, 661) cut flows younger than 179, but the majority of the intrusions are not seen in direct relation to flows as young as 179 (281, 290, 313, 358, 414, 443, 683). Specimen 746 is from an irregular parasitic intrusion which cuts through the upper levels of the thick pile of late basaltic flows of the main shield.

From the field evidence, therefore, it is possible to establish a fairly accurate time sequence for the older extrusive, and some later intrusive, rocks. The younger extrusives and intrusives, however, were both difficult to correlate with any certainty.

A thin section of each rock was examined; in general any specimen that showed evidence of alteration other than minor alteration of olivine<sup>4</sup> was rejected, as were any amygdaloidal lavas. In a few cases (samples TC, 105, 111, 121, 746) it was necessary to relax the selection criteria slightly because the samples were the only ones available from certain important stratigraphic positions. Petrographic descriptions and the locations of the specimens are given in Table 2.

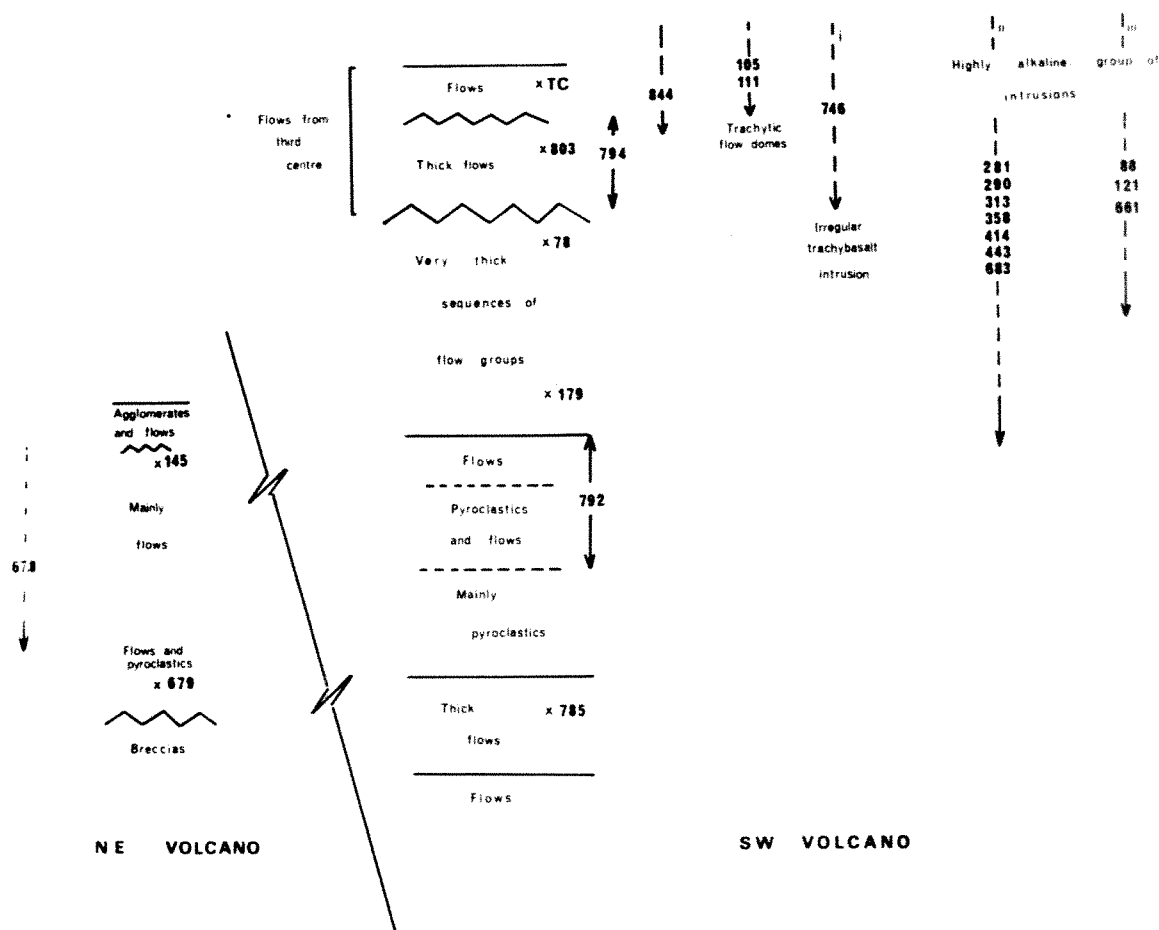

Fig. 2. Positions of dated specimens in simplified stratigraphic chart; arrow heads denote minimum and maximum ages based on field evidence.

In order to avoid sampling errors the rocks were crushed and sieved to 40–80 mesh size. All the ages were measured on whole rock samples.

Argon extractions were made in a 'Pyrex' high vacuum fusion system which was baked overnight at 200° C in order to drive off the majority of adsorbed atmospheric argon from the samples and glassware. Each sample (usually of about 10 g mass) was fused in a molybdenum crucible within the fusion system at about 1,400° C for 20 min by radio frequency induction heating. A tracer of argon-38 ( $\approx 1 \times 10^{-5}$  c.c. S.T.P.) was added before fusion, and purification of the gases was made over hot copper oxide (CuO) and titanium, with a hot tungsten filament to dissociate hydrocarbons (chiefly methane).

The purified argon was led through a Granville-Phillips leak valve directly to a Reynolds all glass bakable mass spectrometer operated in the dynamic mode. The argon was determined in the usual way by isotope dilution. A bulb to dispense argon-38 tracer was used, similar in design to that recently described by Lanphere and Dalrymple<sup>11</sup> but in use at Oxford for many years. Calibration of the argon-38 tracer was made against known volumes of air, and secondary standards including the Massachusetts Institute of Technology biotite B3230.

Three important samples were also analysed for argon using an 'MS10' mass spectrometer. This instrument is free from the mass 36 background (and from memory effects) which can sometimes vitiate results obtained with the Reynolds machine.

Potassium was determined in duplicate by flame photometry, using an 'EEL' flame photometer burning a mixture of air and coal gas and modified by the incorporation of an interference filter peaked at 7666 Å and with a pass band of 96 Å. The sensitivity in this region of the spectrum was improved by replacing the standard photocell by a 'Megatron' infra-red photocell and the precision of observation was greatly enhanced by using a potentiometric chart recorder with the instrument.

A very careful investigation has been made of the interfering effects on the determination of potassium of the presence of other cations and anions. The interference effects found are similar to, but different in detail from, those reported by Cooper for the Perkin-Elmer instrument<sup>12</sup>. A buffering technique has been developed to overcome the interference effects; the buffering solution contains 1,000 p.p.m. of each of the elements sodium, aluminium, magnesium, calcium and iron in chloride form, and is made weakly acid (1,000 p.p.m.) with hydrochloric acid (about 36 per cent HCl) to prevent hydrolysis. The technique now used for potassium analysis makes use of no chemical separation, but involves the addition to both unknown and potassium standard solutions of the buffer solution on a 1:1 basis by volume. Determination of the concentration of potassium in the buffered unknown solution is made by bracketing it between two buffered standard potassium solutions 1 p.p.m. apart in concentration, in the range 1–10 p.p.m. of potassium.

The technique has been calibrated against interlaboratory standards (G1, W1, B3203) and against the neutron activation technique in the range 0.1 per cent–10 per cent potassium, and has been proved capable of an accuracy of  $\pm 1.5$  per cent throughout this range.

For each of the twenty-four specimens dated, potassium analyses were made in duplicate and argon analyses were duplicated on six of the samples. In all cases replicate potassium determinations agree to within 1 per cent, and analysis of inter-laboratory standards leads to an estimate of an absolute accuracy of  $\pm 2$  per cent. The principal factor influencing the errors in the ages is the error in measuring the argon content, which in its turn was principally in error because of the rather large atmospheric argon contamination (ranging from 20 to 70 per cent) associated with these rocks.

In order to be able properly to compute the effect on the age of the errors in the various measured parameters

Table 1

Sample No.	Potassium analysis (wt. per cent K)	Radiogenic <sup>40</sup> A (10 <sup>-8</sup> c.c./g)	Per cent radiogenic argon	Age (× 10 <sup>8</sup> yr)
TC	2.37 ± 0.04	80.4	65	8.5 ± 0.4

443	4.07 ± 0.08	123.7	78	7.5 ± 0.4
661	3.57 ± 0.07	104.5	77	7.3 ± 0.4
678	0.79 ± 0.01	35.9	51	11.4 ± 1.0
679	1.10 ± 0.02	64.3	50	14.6 ± 1.0
	1.11 ± 0.02	61.91*	60	14.0 ± 1.0
683	3.88 ± 0.08	118.4	80	7.7 ± 0.4
746	1.55 ± 0.02	52.1	48	8.4 ± 0.6
785	0.44 ± 0.01	20.1	39	11.3 ± 1.0
792	1.25 ± 0.02	54.4	45	10.9 ± 0.8
794	1.05 ± 0.02	40.4	41	9.6 ± 0.8
803	1.09 ± 0.02	40.2	32	9.2 ± 1.0
844	0.88 ± 0.01	32.9	50	9.3 ± 0.6

Adopted constants:  $\lambda_\beta = 4.72 \times 10^{-10}$  yr<sup>-1</sup>;  $\lambda_e = 0.584 \times 10^{-10}$  yr<sup>-1</sup>;  $^{40}\text{K} = 1.19 \times 10^{-2}$  atom per cent.

\* Argon determined on 'MS10' mass spectrometer.

a straightforward statistical analysis was carried out. The resulting expression for the standard deviation of the age is

$$\sigma(\text{age}) = \frac{1.712 \times 10^4}{(1 + 9.082R)} \cdot \sigma(R) \times 10^6 \text{ yr} \quad (1)$$

where

$$R = 1463 \times [^{40}\text{A}] / [K] \quad (2)$$

where

$$[^{40}\text{A}] = (\text{c.c. S.T.P.}) / \text{g of radiogenic } ^{40}\text{A}.$$

[K] is the weight per cent of potassium and the values adopted for various constants are  $\lambda_\beta = 4.72 \times 10^{-10}$  yr<sup>-1</sup>;  $\lambda_e = 0.584 \times 10^{-10}$  yr<sup>-1</sup>;  $^{40}\text{K} = 1.19 \times 10^{-2}$  atom per cent.

Assuming that the errors propagate independently we may write for  $\sigma(R)$  the expression

$$\sigma(R) = \frac{1463}{[K]} \sqrt{\sigma^2([^{40}\text{A}]) + \frac{[^{40}\text{A}]^2}{[K]^2} \cdot \sigma^2([K])} \quad (3)$$

which, if we assume that  $\sigma([K])/[K] = 1.5 \times 10^{-2}$ —a 1.5 per cent error at the 68 per cent confidence level—reduces to

$$\sigma(R) = \frac{1463}{[K]} \cdot \sqrt{\sigma^2([^{40}\text{A}]) + 2.25 \times 10^{-4} [^{40}\text{A}]^2} \quad (4)$$

It is fairly easy to show, from the expressions used in the determination of argon by isotope dilution, that the standard deviation of the radiogenic argon-40/g,  $\sigma([^{40}\text{A}])$ , depends on two terms according to the relation

$$\sigma^2([^{40}\text{A}]) = \{\sigma^2(T) + \sigma^2(a)\} / m \quad (5)$$

where  $m$  is the mass of sample taken in grams,  $T$  is the total volume of argon (radiogenic plus atmospheric) evolved from the sample and  $a$  is the volume of atmospheric argon evolved from the sample. The standard deviations  $\sigma(T)$  and  $\sigma(a)$  may be computed from the standard errors associated with the measurement of the isotopic ratios of the argon evolved from the sample, atmospheric argon and the tracer argon. The explicit formulae will not be given here. An alternative is to establish  $\sigma(T)$  and  $\sigma(a)$  (in the range of values of  $T$  and  $a$  appropriate to

the study in hand) by replicate analysis; for the St Helena samples  $T$  could be determined with a reproducibility of  $\pm 1$  per cent while  $a$  could be determined to  $\pm 2$  per cent. It then follows that the standard deviation of the quantity  $[^{40}\text{A}]$  is given by

$$100 \cdot \frac{\sigma([^{40}\text{A}])}{[^{40}\text{A}]} = \frac{\sqrt{(4(a/T)^2 + 1)}}{[1 - (a/T)]} \quad (6)$$

The errors quoted in this work are twice the standard deviation calculated from expression (1), using expressions (4) and (6), and are thus calculated at the 95 per cent confidence level.

The potassium/argon ages from Table 1, shown graphically in Fig. 3, may be compared with Fig. 2, which shows the stratigraphic position of the samples as determined in the field. The radiometric ages correlate well with the stratigraphic ordering for those specimens which could accurately be placed stratigraphically. The age for lava flow 78 is believed to be anomalous. Because its stratigraphic position is well determined, and specifically because it is in the flow group cut by the 746 intrusion (dated at  $8.4 \pm 0.6 \times 10^6$  yr, which is in full agreement with the other dates), it is believed that argon has been lost as a result of re-heating by the overlying flow. The ages obtained for the late relic flows (794, 844) suggest

their contemporaneity with the activity of the third centre.

The overlap of the radiometric ages for the two volcanoes still does not solve the problem of the time relations between the centres of activity. Specimen 785 ( $11.3 \pm 1.0 \times 10^6$  yr) is from the lowest levels of the south-western volcano; specimen 145 ( $11.4 \pm 1.0 \times 10^6$  yr) is from the top part of the north-eastern shield, a stratigraphically low specimen from which gives an age of  $14.6 \pm 1.0 \times 10^6$  yr (679). The lack of late intrusives and restricted development of late extrusives in the north-east perhaps strengthen the possibility, suggested by the radiometric ages, that the shift of the eruptive centres, 12 km to the south-west, marked a complete transfer of major extrusive activity.

The radiometric ages establish that the south-western basaltic shield volcano was built up in approximately  $3 \times 10^6$  yr ( $8.5\text{--}11.3 \times 10^6$  yr). The late flows above the unconformity (Fig. 2) appear to be markedly later ( $8.5\text{--}9.6 \times 10^6$  yr) than the bulk of the shield forming extrusives ( $10.1\text{--}11.3 \times 10^6$  yr), and form less than a quarter of the volume of the volcano. The highly alkaline intrusives, volumetrically less than 5 per cent of the total volcanic products, belong to a group significantly younger than the shield as a whole (the average age is approximately  $7.6 \times 10^6$  yr). These late intrusives have been interpreted

Fig. 3. Radiometric ages; all but intrusive rocks are shown in stratigraphic sequence left to right. Intrusives (groups i, ii and iii of Fig. 2) are arranged for simplicity in order of specimen numbers.

as products of a late, highly differentiated magma chamber at a high level in the volcanic pile<sup>14</sup>. It is conceivable from these dates that the magma may have had considerable time in which to differentiate before the intrusion of these late rocks.

The age/volume relationships demonstrate a slowing down in activity throughout the formation of the main volcano. The late flows and minor flank activity appear to have occupied a period of time approximately equal to that taken to build the bulk of the main shield. The volumetrically almost insignificant late alkaline intrusives represent the volcanic history over a comparable period of time. This succession of events presents a close analogy with Hawaiian activity of the Kohala type, where late differentiates are separated by a marked unconformity from alkali basaltic and intermediate flows which form the late parts of the shield<sup>15</sup>; which is tholeiitic in the Hawaiian case.

The total sub-aerial active life of the island is a minimum of  $7.5 \times 10^6$  yr—even the single main volcano presents a minimum active life of  $4 \times 10^6$  yr. This time scale appears comparable with preliminary age determinations on the Canary Islands<sup>7</sup>. In view of the scarcity of data from other islands in the Atlantic, the geochronological results for St Helena and the Canaries strongly suggest that the general conclusions on the active life of volcanic oceanic islands drawn by Gass<sup>8</sup> from geochronological studies of the Tristan group are not tenable. It is clear that the results of studies of the rate of formation of one volcanic pile cannot necessarily be extended as generalizations to others. Furthermore, the conclusions on the Tristan group are themselves based on much less evidence than that available for either St Helena or the Canaries. There is direct evidence only for the rate of formation of Tristan itself, and none for Inaccessible or Nightingale—indeed, the direct geochronological evidence for Nightingale would appear, by itself, to support equally well the hypothesis that that island was built up over a period of approximately  $18 \times 10^6$  yr.

In considerations of how far the results on St Helena support theories of ocean floor spread<sup>1-3,16</sup> two main points should be noted. The rocks forming the island of St Helena above sea level (even allowing for erosion) form approximately 5 per cent of the total volume of the volcanic pile, and represent up to  $7.5 \times 10^6$  yr of its history. These ages cannot be extrapolated down into the pile because of the unknown rate of submarine extrusion. Wilson<sup>1-3</sup> has stressed that the ages which he quoted for oceanic islands were minima, and thus that his calculations of rates of ocean floor spread were maxima. In view of the possible age range from a single island, and the impossibility of extrapolation through the volcanic pile, it would appear that these dates can strictly only be used as minimum dates for the commencement of sub-aerial volcanic activity. It should be emphasized that the date required for correlation with theories of ocean floor spreading is that of the commencement of volcanic activity at the particular centre, and that the rocks recording this lie at the base of the volcanic pile. It is certainly true, however, that the radiometric ages for St Helena reported here support in a general way the concept of ocean floor spreading. It is clear that the formation of St Helena took place more than  $14 \times 10^6$  yr ago, which is certainly much older than the age of volcanism on the North Atlantic Ridge and does in fact accord quite well with the linear correlation between age and distance from the ridge given by Wilson<sup>1</sup>.

Evidence from the Canary Islands, Cape Verde Islands and Tristan da Cunha demonstrates that islands may still be volcanically active when at considerable distances from the crest of the Mid-Atlantic Ridge. Individual islands in the Atlantic have acted as point sources for the prolonged extrusion of magma, and theories of ocean floor spreading must account for this continuity of activity over considerable periods of time (and thus over con-

Table 2. PETROGRAPHIC DESCRIPTIONS OF SPECIMENS

Specimen No.	Description
TC:	Slightly altered, fine-grained trachyandesite. Fayalitic olivine microphenocrysts in good trachytic texture of feldspars and very poikilitic aegirine-augite. Partial alteration of the olivine and groundmass to turbid phyllosilicates.
78:	Very fine grained trachybasalt. "Iddingsitized" groundmass olivines. Phenocrystal titanomagnetite and apatite.
88:	Medium-grained trachyte. Rare fayalitic olivine, and titanomagnetite in a mass of alkali feldspar laths and ragged aegirine-augite.
105:	Highly oxidized, slightly altered trachyte. Altered fayalitic olivine and groundmass. Perfectly unaltered alkali feldspars with trachytic texture.
111:	Slightly altered trachyte with perfect fluidal texture. Fayalitic olivines partially altered to green phyllosilicates. Microphenocrysts of titanomagnetite and sub-poikilitic or anhedral aegirine-augite.
121:	Fine-grained (phonolitic) trachyte. Microphenocrysts of alkali feldspar in a finer grained mass of alkali feldspars and late poikilitic aegirine-augite; rare euhedra of ? hydronepheline. Perfect trachytic texture.
145:	Porphyritic olivine-pyroxene basalt. Slight "iddingsitization" of all olivines. Groundmass very fine-grained: pyroxene, olivine, plagioclase and titanomagnetite.
179:	Porphyritic pyroxene-olivine basalt. Groundmass of fine-grained olivine, pyroxene, plagioclase and titanomagnetite. Slightest trace of "iddingsitization" of phenocrystal olivine.
281:	Phonolite. Phenocrystal alkali feldspar, and small euhedral nephelins, ragged anhedral to sub-poikilitic aegirine/aegirine-augite, in a very fine-grained groundmass of nepheline and alkali feldspar.
290:	Medium-grained phonolite. Alkali feldspar laths in little matrix of smaller laths, anhedral nepheline and very poikilitic aegirine with rare cossyrite.
313:	Medium-grained phonolite. Alkali feldspar prisms in finer mass of feldspar laths, minute nepheline euhedra, titanomagnetites and ragged to sub-poikilitic aegirine.
358:	Fine-grained phonolitic-trachyte. Rare phenocrysts of alkali feldspar in very fine groundmass of feldspar laths, rare nephelins, titanomagnetite, and mossy aegirine-augite.
414:	Medium to fine-grained phonolitic-trachyte. Subhedral alkali feldspar prisms in fine-grained mass of feldspars, minute nephelins, titanomagnetite, and subhedral to sub-poikilitic aegirine-augite.
443:	Medium to fine-grained phonolitic-trachyte with perfect trachytic texture. Minute nepheline euhedra, and ragged sub-poikilitic dark green aegirine-augite.
661:	Phonolitic-trachyte. Microphenocrysts of euhedral alkali feldspar and nepheline in groundmass of alkali feldspar laths, sub-poikilitic aegirine-augite, and very rare fayalitic olivine.
678:	Porphyritic pyroxene-olivine basalt. Groundmass of fine-grained olivine, pyroxene, plagioclase and titanomagnetite. Slight phyllosilicate alteration of the olivine along cracks.
679:	Porphyritic pyroxene, feldspar, olivine, titanomagnetite basalt. Fine-grained groundmass of similar minerals. Slight alteration of olivine along cracks to phyllosilicates.
683:	Medium-grained phonolitic-trachyte. Alkali feldspar prisms in fine-grained mass of alkali feldspar, nepheline, and anhedral to sub-poikilitic aegirine-augite/aegirine.
746:	Highly oxidized trachybasalt, with olivine, plagioclase laths with weak fluidal texture.
785:	Porphyritic olivine-pyroxene basalt. Fine-grained groundmass. Very slight traces of "iddingsitization" of olivines.
792:	Medium-grained basalt; slightly "iddingsitized" olivine microphenocrysts in mass of plagioclase, titanomagnetite, and granular pyroxene. Late interstitial biotite; very slight traces of green phyllosilicates in patches in the groundmass.
794:	Basalt. Microphenocrysts of olivine and plagioclase in finer groundmass of pyroxene, titanomagnetite, plagioclase and olivine. Slight phyllosilicate alteration of olivine microphenocrysts.
803:	Fine-grained basalt. Microphenocrysts of olivine and plagioclase in a groundmass of olivine, titanite, plagioclase and titanomagnetite. Slight alteration of the olivine along cracks to phyllosilicates.
844:	Porphyritic olivine-pyroxene basalt. Fine-grained groundmass of plagioclase, pyroxene, olivine and titanomagnetite.

siderable distances), perhaps by the parallel movement of the magma source with each volcanic island.

We thank the Natural Environment Research Council for support. We also thank S. Moorbath and J. G. Jones for helpful examination of the manuscript.

# An Evolutionary Sequence for Strong Radio Sources

by

M. SIMON

Center for Radiophysics and Space Research,  
Cornell University, New York

F. D. DRAKE

Arecibo Ionospheric Observatory\*,  
Arecibo, Puerto Rico

The authors attempt to show that the results of Heeschen on extra-galactic radio sources can be simply interpreted in terms of a consistent evolutionary sequence. They suggest that only three stages of evolution are required: particle injection into a jet-like structure; adiabatic expansion of a relativistic gas; and, finally, pressure equilibrium with the inter-galactic gas. This suggests that the quasars are at cosmological distances.

HEESCHEN<sup>1</sup> has recently compared the 1,400 Mc/s absolute radio luminosity,  $L$ , and surface brightness,  $B$ , of many extra-galactic radio sources, and found a remarkable, well defined correlation. It is the purpose of this article to suggest that Heeschen's results may be interpreted as evidence of a possible radio source evolutionary sequence which is very similar to that suggested by Gold<sup>2</sup>. We shall find that the location of a source in the sequence is determined by the evolutionary stage extant: particle injection, adiabatic expansion of a relativistic gas, or pressure equilibrium with the inter-galactic medium. The location is also correlated with spectral index, which reflects the age of the radiating material.

To facilitate the discussion we have reproduced Heeschen's results in Fig. 1. Heeschen found that the quasi-stellar objects fall on a zero slope sequence in the  $\log L$ - $\log B$  plane at the absolute luminosity  $L \approx 10^{28}$  W/c/s (on the assumption that they are at cosmological distances) and that the radio galaxies form a well defined sequence adjoining that of the quasi-stellar objects with a mean slope of about 1.5. Spiral and irregular galaxies are clustered at the base of the radio galaxy sequence. Several sources are outside these sequences, particularly the cores of three core-halo objects: M87, 3C 218, and Perseus A. Their halo components are found in the radio galaxy sequence. Outside the sequences, and in the same region as the cores, are also one Seyfert galaxy, NGC 1068, and one peculiar galaxy, M82. It is significant, as pointed out by Heeschen, that each anomalous object is known to be associated with a violent event in its nucleus.

The quasi-stellar object sequence indicates that the quasi-stellar objects have similar intrinsic luminosities at 1,400 Mc/s. There is other evidence in support of this observation. If the quasi-stellar objects do have a fixed intrinsic luminosity at a particular frequency then there should be a relation between their apparent radio magnitude at that frequency and their red-shift. Hoyle and Burbidge<sup>3</sup> have explored this possibility by plotting the apparent radio magnitude at 178 Mc/s against  $(1 + \log z)$ , where  $z$  is the usual red-shift, and showed that the result was simply a scatter diagram. Bolton<sup>4</sup>, however, has constructed a similar diagram for the apparent radio magnitudes at the frequency 1,400 Mc/s where the effects of self-absorption tend to be less, and has shown that if only the quasi-stellar objects with spectral indices less than 0.5 are considered then the scatter is considerably reduced, indicating that such quasi-stellar objects may be better characterized by a fixed intrinsic luminosity. Further, Kafka<sup>5</sup> has calculated the intrinsic spectra for 31 quasi-stellar objects in the 3C revised catalogue by

applying to the observed spectra the cosmological corrections appropriate to Friedmann models with several values of  $q$  and zero cosmological constant. Inspection of his results for  $q = -1$  (steady state universe) indicates that while the scatter in luminosities at the frequency 1,500 Mc/s for all the 31 quasi-stellar objects is about a factor of 250, if only the five in his sample with strikingly flat spectra are considered (3C 273, 3C 345, 3C 138, 3C 309.1, 3C 286), the scatter in their luminosities is reduced to a factor of about 20. For other values of  $q$  the scatter in both groups is less. Even with such limited statistics, the indications are that the quasi-stellar objects with flat spectra may have a sharply bounded intrinsic luminosity. Using the table of radio source parameters compiled by Howard *et al.*<sup>6</sup>, we find that half the quasi-stellar objects plotted by Heeschen<sup>1</sup> have spectral indices less than 0.6 so that we may perhaps expect those to be of the same intrinsic luminosity.

There is evidence that the spectra of radio galaxies steepen with time. Kellermann<sup>7</sup> has compared the spectral index with the projected linear separation of the two components in double radio sources and has shown that there is an increase in the spectral index with increase in the separation of the components. Cohen, Gundersmann and Harris<sup>8</sup> have demonstrated that quasi-stellar objects

Fig. 1. The absolute radio luminosity,  $L$ , and surface brightness,  $B$ , at 1,400 Mc/s for various radio sources<sup>1</sup>. We have added the possible evolutionary paths I, IA, II, IIA, and III.

\* Operated by Cornell University with the support of the Advanced Research Projects Agency under a research contract with the US Air Force Office of Scientific Research.

with flat spectra are particularly strong scintillators and are thus sources of exceptionally small angular size. Thus the radio emission of quasi-stellar objects with flat spectra seems to originate from a small volume and they are likely to be young.

Setting aside discussion of the quasi-stellar object sequence for the moment, we shall show that Heesch's results suggest the following evolutionary path of a typical radio source. In the first phase a violent event occurs in a small region inside a galaxy and the radio source makes its initial appearance in the  $\log L$ - $\log B$  plane as an object of high brightness but small luminosity. It is likely, as noted by Gold<sup>2</sup>, that while the relativistic gas produced by the violent event is in the galaxy, it is not free to expand isotropically, but rather is guided by the galactic magnetic fields into a jet such as is observed in M87. In its early stages, then, the radio source will in general have a core-halo structure, and as we shall show, its core will evolve along one of the vertical lines in Fig. 1, say, path I, with the direction of increasing time indicated by the arrow.

The second phase occurs when the relativistic gas has reached the inter-galactic medium and is thus able to expand more nearly isotropically as a "cloud". The slope of the evolutionary path in this phase will be shown to be

$$\frac{d \log L}{d \log B} \approx 0.7$$

The final phase is reached when the cloud of relativistic particles has stopped expanding because it has come into pressure equilibrium with the inter-galactic medium. The external pressure on the cloud may be caused by the ambient magnetic pressure of the inter-galactic medium<sup>2</sup>, or may be of dynamical origin as a result of the motion of the cloud through the inter-galactic medium (unpublished work of D. S. DeYoung). Even though the cloud has stopped increasing its size, it will may have sufficient transverse momentum to continue to separate from its parent galaxy. The relativistic particles continue to lose energy by synchrotron radiation so that their energy spectrum steepens, but the size of the cloud remains fixed. Thus this phase will be shown to be characterized by a slope of 1 in the  $\log L$ - $\log B$  plane.

We now discuss each of these evolutionary stages in greater detail. For an optically thin source of average emissivity  $\epsilon$ , the absolute luminosity,  $L$ , and surface brightness,  $B$ , are

$$L = \epsilon V \quad B = \epsilon V / \Omega \quad (1)$$

where  $V$  is the volume of the source and  $\Omega$  the solid angle it subtends. In the case that the energy spectrum of the relativistic electrons is

$$n(r, E) dE = K(r) E^{-m} dE \quad (2)$$

the volume emissivity resulting from synchrotron radiation is

$$\epsilon_v \propto K H^{\frac{m+1}{2}} v^{\frac{1-m}{2}} \quad (3)$$

where  $H$  is the average magnetic field strength and  $v$  is the frequency of the radiation. It will be useful to replace  $K$  in (3) by its dependence on the total relativistic electron number density  $N$  which is the integral of (2) between the upper and lower energy cut-off,  $E_2$  and  $E_1$ , respectively. As  $(E_2/E_1) \gg 1$ , we may write (3) as

$$\epsilon_v \propto \begin{cases} N E_1^{m-1} H^{\frac{m+1}{2}} v^{\frac{1-m}{2}} & m > 1 \\ N \log \frac{E_2}{E_1} H v^0 & m = 0 \\ N E_2^{m-1} H^{\frac{m+1}{2}} v^{\frac{1-m}{2}} & m < 1 \end{cases} \quad (4)$$

We now consider the evolutionary path during the first phase. For guidance, we take the core of M87 as representative of the cores of core-halo objects. We can characterize these sources by a jet inside the body of a galaxy. We take the jet to be continuously supplied with relativistic particles by the explosions inside the galaxy, and as forcing its way out in such a way that it increases its length  $l$  while maintaining the same diameter. Then we may take  $N \approx$  constant,  $H \approx$  constant, so that  $L \propto l$ , and  $B \approx$  constant. Thus, as the jet lengthens, the source evolves in the direction of increasing luminosity along a line of constant brightness. The paucity of core-halo objects suggests that this stage of evolution is particularly rapid.

The evidence clearly suggests that the jets eventually reach the inter-galactic medium where they evolve into the common double-lobed radio structure. During this second phase we consider the cloud of relativistic particles to be roughly spherical (of radius  $r$ ) and to have its full complement of relativistic particles. It expands until it comes to pressure equilibrium with the inter-galactic medium. During the expansion, by continuity and flux conservation,  $N$  is proportional to  $r^{-3}$ ,  $H$  is proportional to  $r^{-2}$ , and if in addition, the expansion is adiabatic (with ratio of specific heats  $\gamma = 4/3$  as appropriate to a relativistic gas) then  $E$  is proportional to  $r^{-1}$ . From (4) we have that (provided that  $m \neq 1$ )  $L$  is proportional to  $r^{-2m}$  and  $B$  is proportional to  $r^{-2m-2}$ . Hence

$$L \propto B^{m/(m+1)} \quad (5)$$

In the expansion in the second phase therefore the radio sources should evolve with a slope of  $m/m+1$  in the  $\log L$ - $\log B$  plane. Taking  $m \approx 2.4$  which is a mean value for double radio sources, the slope is  $\approx 0.7$  which we have drawn in Fig. 1 as path II. As  $m$  increases with time the slope steepens to 1. The increase in slope towards the value is evident at the lower luminosity end of path II.

We observed in Fig. 1 that in the radio galaxy portion of the diagram beyond path II there is a steepening in the radio galaxy sequence. It is unlikely that this is caused by the steepening of the slope  $m/m+1$ , as calculated for the expansion phase, because the radio galaxies in this portion of the  $\log L$ - $\log B$  diagram have about the same spectral indices as those lying near path II. We suggest rather that in the final stage of the evolutionary sequence the cloud of relativistic particles has come to pressure equilibrium with the inter-galactic medium and no longer expands. The dimensions of the cloud are fixed, so that in this stage of evolution the luminosity and brightness remain directly proportional to each other and the evolutionary path has slope 1 in the  $\log L$ - $\log B$  diagram (path III). The evolution is of course in the direction of decreasing luminosity since the emissivity decreases with time as a result of the synchrotron losses of the relativistic particles.

Looking now at the surprisingly flat sequence described by the quasi-stellar objects, we note that the nearly zero slope is likely a consequence of the flat intrinsic source spectra. It is natural to suggest that we are dealing here with young sources just beginning their expansion, in the second phase, into the inter-galactic medium. They have commenced their evolution with a rapid particle injection into a smaller volume than the radio galaxies, so that the first phase has followed path IA. The energy spectrum of the relativistic electrons has not yet been steepened by losses. It is not known what should be assumed for the original unsteepened energy spectrum, but the criterion of frequency spectrum flatness used above indicates that we should take  $m < 2$ . For the special case  $m = 1$  the slope in the  $\log L$ - $\log B$  plane is  $1/2$  and for smaller  $m$ s it decreases as  $m/m+1$  to 0 when  $m = 0$ ; that is when we have a flat energy spectrum. This range of values for the slope seems to be compatible with Heesch's<sup>1</sup> observed quasi-stellar object sequence. As these sources continue

to evolve and steepen their energy spectrum, their evolutionary path IIA steepens its slope into that of the "normal" expansion phase, path II.

In summary we have attempted to show that Heesch's observations may be interpreted in terms of a consistent evolutionary sequence. We must emphasize that at any one time different radio components of the same object may be found in different phases of the evolution. For example, while the intense double radio sources are in the second or final phase, the emission of the parent galaxy may be located among that of the normal spirals and irregulars.

Throughout the discussion we have implicitly assumed the cosmological nature of the quasi-stellar objects. We suggest that the radio emission properties of the quasi-

stellar objects fit so naturally into the proposed sequence that it argues that they are at cosmological distances.

We thank T. Gold and D. S. DeYoung for helpful discussion.

## Specific Adsorption of Anions

by

F. J. HINGSTON\*

R. J. ATKINSON

A. M. POSNER

J. P. QUIRK

Department of Soil Science and Plant Nutrition,

The specific adsorption of anions depends on the  $pK$  values of the anion acids. The adsorbed anions confer a negative charge on the surface displacing the zero point of charge to lower  $pH$  values.

ADSORPTION of anions at mineral surfaces is important in soils because of the limit this process imposes on the availability of plant nutrients which occur naturally as anions or are added in anionic form in fertilizers. The nature of an oxide solution interface is determined both by the hydrogen ion concentration and the presence of specifically adsorbed anions within the co-ordination shell of, for instance, an iron atom.

Protons and hydroxyl ions are the potential determining ions<sup>1</sup> in the non-specific adsorption of such anions as chlorine and nitrate on kaolinite<sup>2</sup>, ferric<sup>3</sup> and other oxides. When adsorption of protons occurs in excess of that for hydroxyl ions the surfaces become positively charged, the magnitude of the charge increasing with ionic strength at any given  $pH$  below the zero point of charge (ZPC). In these circumstances the positive charge is located on the inner Helmholtz layer with the balancing anion located either in the outer Helmholtz layer<sup>4</sup> or the diffuse double layer. Such adsorption is termed non-specific.

Changes in bulk concentration of the anions, orthophosphate, pyrophosphate, tripolyphosphate, selenite, silicate and fluoride after adsorption show that these anions are bound to a far greater extent than would be predicted from their concentrations when compared to a non-specifically adsorbed anion. At any  $pH$  there is a maximum adsorption<sup>5</sup> of such anions and when these maxima are plotted against  $pH$ , curves of the type shown in Fig. 1 are obtained (adsorption envelope). These curves are insensitive to changes in the ionic strength so that the adsorption is not determined by the properties of the diffuse double layer or the outer Helmholtz layer.

For the silicate and fluoride ions there is an adsorption maximum at the  $pK$  value, while for orthophosphate

there is a discontinuity at each  $pK$  value, the one at the last  $pK$  value being the most marked. The good linear correlation (Fig. 2) between the  $pK$  values of a number

Fig. 1. Adsorption envelope. Variation in the maximum adsorption of silicate and orthophosphate on goethite with  $pH$  at  $20^\circ C$  in the presence of 0.1 molar sodium chloride as supporting electrolyte:  $\circ$  silicate;  $\Delta$ , orthophosphate. Broken curves indicate the relationship obtained from the equation. Amount of anion adsorbed =  $2V\sqrt{\alpha(1-\alpha)}$  where  $V$  is the amount of anion adsorbed at  $pH$  9.2 for  $H_4SiO_4$  and  $pH$  11.3 for  $H_3PO_4$ ,  $\alpha$  is the degree of dissociation of  $H_4SiO_4$  and  $HPO_4^{2-}$ . a,  $H_3PO_4$ ,  $pK_2$ ; b,  $H_4SiO_4$ ,  $pK_1$ ; c,  $H_3PO_4$ ,  $pK_1$ .

\* CSIRO Division of Soils.

of weak acids and the  $pH$  values at the discontinuities on the adsorption envelopes indicates the wide applicability of this relationship. The results indicate that the undissociated free acid and the most highly charged form of the anion are not adsorbed when present alone, that is, at low and high  $pH$  with respect to the  $pK$ , but that the presence of both forms of the anion is necessary before adsorption can take place. Thus the requirement for adsorption of an anion of a weak monobasic acid is the presence of both a proton donor (acid) and acceptor (salt).

It can be shown that the amount of adsorption should be proportional to  $2\sqrt{\alpha(1-\alpha)}$  where  $\alpha$  is the proportion of the most highly charged form of the anion and the adsorption envelope should pass through a maxima at the  $pK$  value and be described by a relationship,

$$A = 2V\sqrt{\alpha(1-\alpha)} = 2V\sqrt{\frac{K[H^+]}{(K+[H^+])^2}} \quad (1)$$

where  $A$  is the amount of the ion adsorbed per unit weight of adsorbent,  $\alpha$  the degree of dissociation of the acid or acid anion in solution,  $V$  the amount of ion adsorbed at the maximum, and  $K$  is the dissociation constant of the most highly charged anion that is adsorbed.

If the acid is polybasic (for example, phosphoric acid), then the acid anions (for example,  $HPO_4^-$ ) produced with decreasing  $pH$  past the last  $pK$  value can themselves accept and donate protons without requiring the presence of two types of anion. Instead of passing through a maximum the envelope shows a marked decrease in slope as it passes through the last  $pK$  value (Fig. 1, phosphate).

Fig. 1 shows that equation (1) applies reasonably well to the results for the rise to the last  $pK$  of phosphoric acid. The deviations for silicic acid at the extremes of  $pH$  must be caused by an interaction between the ions and the surface and/or the ions already adsorbed which is not taken into account.

For a polybasic acid after the "envelope" passes through the last  $pK$  it follows a Temkin isotherm (Fig. 1, phosphate), probably because of a linearly increasing interaction energy as the surface coverage increases. As further  $pK$  values are negotiated the adsorbing species

Fig. 2. The relationship between the  $pK$  values for weak acids and the  $pH$  for breaks in slope of the curve for maximum adsorption against  $pH$ . All acid dissociation constants, except  $pK_3$  for  $H_3PO_4$  and  $H_3AsO_4$ , were determined in 0.1 molar sodium chloride. Approximate values for the two exceptions were obtained from values given in the literature. Note that fluoride is not adsorbed at  $pH$  values higher than the natural zero point of charge of the oxide. b, The negative charge contributed to the surface/mole of silicon adsorbed ( $E$ ), as a function of  $pH$  and ionic strength of the supporting electrolyte.  $\bullet$ , 0.01 molar sodium chloride;  $\blacktriangle$ , 0.1 molar sodium chloride;  $\blacksquare$ , 1.0 molar sodium chloride.

undergoes an abrupt diminution in charge resulting in a change in slope of the Temkin regions of the "envelope" at that  $pH$ . The direction of change is determined by the net effect of the interactions between ions on the surface and the ion/surface interaction. When the undissociated acid species becomes the dominant form the envelope should fall following equation (1).

From acid/base titration curves in the presence and absence of specifically adsorbed anions and the adsorption measurements the effect of the specifically adsorbed anions on the surface charge has been determined and some results presented in Fig. 3. The zero point of charge (ZPC) is shifted to more acid values and thus specific adsorption of an anion renders the surface more negative. This it must do by entering the inner Helmholtz layer<sup>4</sup>, that is the first co-ordination sphere of the metal ions on the oxide surface, through displacement of a co-ordinated hydroxyl ion. The displacement is a ligand exchange reaction. A negative charge is developed only if a proportion of the hydroxyl ions liberated from the inner layer is in effect retained by the surface through the formation of water as shown in Fig. 4, i-iii. This may be contrasted with the formation of a positive charge balanced by non-specific adsorption and non-specific exchange (Fig. 4, iv and v).

These ideas explain why weak acid anions show maximum adsorption at about the  $pK$  value, since at this  $pH$  the displaced hydroxyl can be retained by adsorption and ionization of the acid form of the anion.

Fig. 4. Anion reactions at the oxide/solution interface. (i) Neutralization of positive charge at pH values below the ZPC; (ii) ionization of a proton of an adsorbed acid anion; (iii) enhancement of the tendency of the surface itself to acquire a negative charge; (iv) non-specific adsorption; (v) non-specific exchange.

The charge ( $\sigma$ ) per unit weight of adsorbent in the presence of the adsorbed anion is given by the expression,

$$\sigma = \sigma_0 + AE$$

where  $\sigma_0$  is the charge per unit weight of adsorbent in the absence of specific adsorption and  $E$  the charge contribu-

tion per adsorbed ion. An example of the variation in  $E$  is given in Fig. 3b.  $E$  is the resultant of the actual exchange of the anion for the hydroxyl ion and the uptake of this ion by the surface in the presence of the anion, that is, of processes (i), (ii) and (iii).

$A$  and  $E$  may be varied independently of one another by change of anion, ionic strength and anion concentration and the same charge can be made up in any number of ways. Thus, with varying pH,  $\sigma$  could have several maxima and minima and more than one zero point. For example, if all the adsorbed anion is removed through pH change before the natural ZPC of the surface is reached, then two ZPC could be obtained (Fig. 3).

The concepts discussed here also explain the observation that anions specifically adsorbed at a given pH could not be desorbed<sup>5</sup> by washing with a solution of non-specifically adsorbed anions (for example, chlorine ions) at the same pH and ionic strength. It is essential for desorption of specifically adsorbed anions to make the charge on the surface more negative than the equilibrium value at which adsorption took place. Non-specifically adsorbed anions cannot make the charge more negative at constant ionic strength and thus are ineffective. Anions capable of specific adsorption to a greater extent than the anion on the surface can, however, make the surface more negative, liberating hydroxyl ions which result in desorption. In essence the same effect, that is, an increase in the net negative charge, is accomplished by raising the pH, thus increasing the adsorption of hydroxyl ions.

## Immunological Reactivity of Lymphoid Cells after Treatment with Anti-lymphocytic Serum

by

L. BRENT

T. COURTENAY

G. GOWLAND\*

Department of Zoology,  
University of Southampton

Immunological reactivity of lymphoid cells after treatment with anti-lymphocytic serum has been measured by their ability to mount a graft-versus-host reaction. This technique makes it possible to test the "blindfolding" hypothesis of ALS action.

It is now well established that anti-lymphocytic serum (ALS) prepared in animals of another species can prolong the life of homografts very significantly when injected into the recipients at or soon after transplantation<sup>1-11</sup>. Several hypotheses have been proposed to explain its mode of action, among them Medawar and Levey's suggestion of lymphocyte "blindfolding"<sup>8</sup>, that is, that coating of lymphocytes with xenogeneic protein in the form of antibody prevents the receptor sites of the cells from recognizing the allogeneic antigens of the graft.

The experiments described here combine the more conventional assays of ALS, such as determination of antibody titres and effect on skin homograft survival,

with an assay based on the graft-versus-host reaction (runt disease) which is aroused when allogeneic lymph node cells are injected into newborn mice. This assay has the advantage of measuring the reactivity of serum-treated cells in an antibody-free environment.

Five New Zealand white rabbits were injected with  $300 \times 10^6$  CBA mouse lymph node cells on days 0, 7 and 15. Immediately before the third injection 50 ml. of blood was taken from each animal, and they were all bled out on day 29. All sera were pooled, heated at 56° C for 30 min and absorbed three times with CBA red blood cells freed from white cells by repeated filtration through glass wool. Absorptions were carried out overnight at 5° C and the ratio of packed red cells and serum was approximately 1 : 10. The serum (ALS 2266) was sterilized

\* Present address: Department of Bacteriology, The London Hospital Medical College, London, E1.

by Seitz filtration and stored at  $-20^{\circ}\text{C}$ ; it was non-lethal to mice injected intravenously with 0.5 ml. Normal rabbit serum (NRS) was handled in the same way.

Agglutinins to nucleated cells were estimated in the following way. Two-fold dilutions of serum were prepared in Ringer-phosphate buffer (pH 7.4) containing 5 per cent NRS. To each dilution an equal volume of lymphoid cells suspended in the same medium was added, the final concentration of the cells being  $6 \times 10^6/\text{ml}$ . The tubes were gently shaken at room temperature for 1 h and scored microscopically.

Red cell agglutinins and lysins were measured as follows. For agglutinins, two-fold dilutions (0.5 ml.) of serum in 0.1 per cent polyvinylpyrrolidone-saline received 0.05 ml. of a 2.5 per cent suspension of mouse red blood cells. The tubes were shaken gently for 2 min and left at  $4^{\circ}\text{C}$  overnight. The degree of agglutination was ascertained by viewing the bottom of the tubes in a concave mirror. For lysins, tubes were set up as described here except that dilutions were made in normal saline. After shaking, the tubes were incubated at  $37^{\circ}\text{C}$  for 30 min; 0.25 ml. of a 1:3 dilution of fresh guinea-pig serum was then added to each tube, and, after shaking, the tubes were incubated for a further 30 min. The degree of lysis was estimated by the colour of the supernatant after centrifugation.

To detect antibody on the surface of peripheral blood cells, smears were prepared from the blood of ALS-treated mice and fixed in 95 per cent ethanol for 10 min. The presence of rabbit gamma globulin on white blood cells was then demonstrated using a fluorescein-labelled goat anti-rabbit globulin (Burroughs Wellcome) and the standard sandwich technique described by Nairn<sup>12</sup>.

Skin was grafted by the method of Billingham and Medawar<sup>13</sup>. Recipients were injected with 0.5 ml. of serum 2 and 5 days after grafting, and in this we followed Medawar and Levey<sup>8</sup>, although in our experiments the serum was given intraperitoneally. Epidermal cell suspension was prepared from tails of *CBA* mice essentially as described by Medawar<sup>14</sup>.

The graft-versus-host assay was carried out in the following way. One ml. of ALS was injected intraperitoneally into each female *C57Bl* recipient and cervical, axillary and inguinal lymph nodes were removed at appropriate intervals. Cell suspensions were prepared in Ringer-phosphate solution (pH 7.4)<sup>15</sup> containing 5 per cent heated *C57Bl* serum; the final cell concentration was usually  $20 \times 10^6/\text{ml}$ . Newborn *A* strain mice were injected intravenously within 20 h of birth with 0.05 ml. of the suspension, that is, with  $1 \times 10^6$  cells. These experiments were controlled by using cell donors treated with normal rabbit serum (NRS).

*In vitro* treatment of lymph node cells with ALS was carried out at room temperature at a cell concentration of  $25 \times 10^6/\text{ml}$ . Serum concentrations varied from 1:20 to 1:500 (final concentrations). The preparation of the suspensions was as here, except that the medium consisted of ninety-five volumes of Ringer-phosphate solution and five volumes of 4 per cent dextran ('Intradex', Glaxo) and clumps were removed by filtration through cotton wool. After exposure to ALS the cell suspension was diluted by the addition of two volumes of Ringer-phosphate without dextran and spun at 1,500*g* for 5 min. They were washed again in Ringer-phosphate solution and finally resuspended in medium. *In vitro* treatment with ALS caused clumping that was proportional to the concentration of the serum, and for most experiments a final concentration of 1:100 was accepted as optimal. Cell clumps were removed by filtration through cotton wool, and a considerable loss of cells occurred at this stage.

Cells were trypsinized at concentrations of  $40 \times 10^6/\text{ml}$ . at room temperature and at a pH of about 7.4. The concentration of trypsin (Difco, 1:250) was 0.05 per cent, and the duration of exposure 45 min. At the end of the incubation period the suspension was cooled to  $5^{\circ}\text{C}$  and

diluted with two volumes of medium; it was then spun at 1,300*g* for 5 min and resuspended in fresh medium.

Incubation with and handling in trypsin damaged many lymph node cells and the number of cells was markedly reduced, but after the final resuspension the number of non-viable cells was negligible. Viability was determined by dye exclusion tests with nigrosin, the final concentration of the dye being 0.01 per cent. All counts were made 3 min after addition of the dye, which had previously been dialysed.

Table 1 summarizes the ability of whole serum to agglutinate lymph node cells, thymocytes and epidermal cells from several strains of mice. Although there was no sign of strain specificity and titres were as strong against thymocytes as they were against lymph node cells, *CBA* epidermal cells registered very low titres. On the face of it this suggests that lymph node and thymus cells have antigens that are absent from the surface of epidermal cells, and that this may be so is underlined by our finding that five sera produced by the injection of rabbits with mouse epidermal cells had high titres against epidermal cells (1,024, 512, 1,280, 640, 1,280) but low titres against lymph node cells (64, 8, 8, 8, 16) (unpublished data). Furthermore, when tested *in vivo* these sera prolonged the life of *A* strain skin grafts on *CBA* mice by only 3 days, an observation which could, however, mean that the timing of our immunization schedule was unsuitable (compare ref. 8; ALS can be successfully absorbed with a variety of tissues).

The cytotoxic titre of ALS 2266 was 256-512.

\* The haemolytic titre (guinea-pig complement added) was identical.

† 7S and 19S fractions prepared on a  $44 \times 3$  cm 'Sephadex G-200' column.

‡ 2-Mercaptoethanol.

The suggestion that there may be some degree of tissue specificity certainly deserves further investigation. Meanwhile, from a clinical point of view it would seem prudent to use only lymphoid tissues in the preparation of ALS.

It will also be seen from Table 1 that the lymph node cell agglutinins reside mainly in the 7S fraction, an observation in agreement with the data of James and Medawar<sup>16</sup>, who find that 19S fractions are virtually inactive when tested *in vivo*.

Notwithstanding the lack of strain specificity so far as agglutinating antibodies are concerned, a clear-cut difference was found in the ability of the serum to prolong the life of *A* strain skin homografts on *CBA* and *C57Bl* recipients (Table 2). The implications of this are not at all clear; it might suggest that agglutinating antibodies are not a sound guide to the *in vivo* reactivity of ALS. At any rate, there can be little doubt that a measure of

Serum (0.5 ml.) was injected intraperitoneally 2 and 5 days after skin-grafting.

strain specificity exists, for our observation is confirmed and extended by experiments on another serum (unpublished data).

A four-fold drop in the number of circulating white cells occurred within 4 h when 1 ml. of ALS was injected intraperitoneally into ten adult *C57Bl* males, which were bled alternately in groups of five, and this low level was maintained for 24 h (Fig. 1a). The proportion of lymphocytes also declined (Fig. 1b), and the absolute number of circulating lymphocytes reached its nadir by 12 h, when it was about one-eighth of its normal value. Recovery occurred remarkably quickly and by the fourth day the number of cells was back to normal. The rapidity with which both the drop and recovery of lymphocytes came about was more extreme than that observed by Levey

and Medawar<sup>8</sup> in *CBA* mice, and the rapid rate of recovery argues the more strongly against the possibility that non-reactivity of mice treated with ALS is primarily caused by depletion of circulating lymphocytes<sup>9</sup>.

The data on the graft-versus-host assay in newborn mice are summarized in Table 3 and Fig. 2. Although lymph node cells from donors treated with NRS almost invariably caused the recipients to die by the sixteenth day, cells from donors taken 2 days after intraperitoneal injection of a single dose of 1 ml. of ALS allowed 64 per cent of the recipients to survive into adult life. This protective effect was not significant until 24 h after serum injection; it was at its peak on days 1-6; the decline observed thereafter was first rapid and then relatively slow, until on day 28 it reached the control value of 0.

\* Serum treatment = 1.0 ml. of ALS or NRS intraperitoneally at time 0.

† Animals grafted when 2 months old (see Table 5).

That the effect of the serum had a "latent period" of about 24 h suggests that its action during this period was principally on circulating cells rather than on the cells sequestered in the lymphoid organs. This suggestion has some appeal in view of the fact that at 4 h about 90 per cent of circulating white cells were found to be coated with fluorescein-conjugated antibody (Fig. 1c). Our attempts to collect blood lymphocytes 4 or 12 h after injection to test their reactivity were frustrated because there were so few lymphocytes and they tended to agglutinate badly during extraction.

The percentage of circulating cells coated with antibody was maintained between 12 h and 3 days, and then it went into a fairly rapid decline which slowed down after day 5. Except in the first 12 h the percentage of coated

cells therefore roughly followed the reduction in *in vivo* responsiveness of lymph node cells. As unresponsiveness to skin homografts is in force at a time when relatively few cells can be expected to show visible signs of coating, it must be inferred that (a) antibody is present on the surface but in amounts that would be difficult to trace by the fluorescent antibody technique, or (b) "blindfolding" or some other consequence of surface-attached protein plays a part in the early phase, but retention of antibody on the surface is no longer necessary once the cells have gone through one or more cell divisions, or (c) "blindfolding" is not involved at any stage, coating of cells being merely incidental to the induction of unresponsiveness through other phenomena such as "sterile activation".

Table 5. SURVIVAL OF A STRAIN MICE INJECTED INTRAVENOUSLY, WITHIN 20 H OF BIRTH, WITH  $1 \times 10^6$  *C57Bl* LYMPH NODE CELLS TREATED *in vivo* WITH 1 ML. OF ALS FOLLOWED 2 DAYS LATER BY *in vitro* EXPOSURE TO TRYPSIN

\* Grafted with *C57Bl* skin at 2 months; normal survival time.

Some of the survivors were grafted with *C57Bl* skin when they were 2 months old. One would expect few of them to be tolerant, for they had received only  $1 \times 10^6$  cells neonatally<sup>17</sup>. It is therefore interesting that 2/53 were tolerant (Table 4), suggesting that in these animals the cells had remained viable. The question of whether the cells treated with serum survive after injection into newborn mice is being carefully investigated, and will be discussed elsewhere<sup>18</sup>.

Table 5 gives the results of an experiment in which an attempt was made to restore reactivity to cells treated with ALS by exposing them to the action of trypsin. Although this is so far the only experiment of its kind, we give the results because it is internally well controlled (the experiment has since been repeated with very similar

results<sup>18</sup>). A cell suspension was prepared from the lymph nodes of *C57Bl* mice 2 days after intraperitoneal injection of 1 ml. of ALS—that is, at a time when suppression of responsiveness is near its peak. The experiment included a group of recipients that had received cells untouched by trypsin as well as recipients of cells treated with NRS: tentative as any conclusion must be at this stage, the data (Table 5) suggest that it may indeed be possible to restore reactivity, for the cells exposed to trypsin had the same level of reactivity as the controls. This result cannot be caused by any non-specific action of trypsin unless it is postulated that trypsin enhances immunological reactivity—a possibility that can be dismissed because NRS-treated, trypsinized cells behaved normally in this and in other experiments.

*In vitro* exposure of lymph node cells to ALS for as little as 30 min at room temperature effectively prevented mortality (Table 6), and it was shown that almost all the cells had been coated; even exposure for 1 min, followed immediately by washing, had a slight effect. Concentrations of ALS down to 1:100 gave good protection to neonatal cell recipients, but there was a rapid fall-off in efficacy with lower dilutions, 1:500 being indistinguishable from NRS controls. When higher doses of cells ( $5$  or  $10 \times 10^6$ ) exposed to 1:100 ALS were injected there was some delay in mortality, but only one mouse survived to be grafted with *C57Bl* skin: it was immune. The absence of tolerance in this one animal does not necessarily prove that cells treated *in vitro* with ALS do not survive in their hosts, for the animal may have been merely one of those in which the host-versus-graft reaction had gained the upper hand. While it is true that, judged by dye exclusion tests, about 95 per cent of the cells were viable at the time of injection, it may nevertheless be argued that cytotoxic effects may have been produced by

the presence of complement in the recipients. Experiments are in progress to test the validity of this objection, and preliminary results indeed suggest that cells treated *in vitro* do not always survive in their hosts<sup>18</sup>.

This work was supported by a grant from the Medical Research Council. We thank Dr R. J. Batchelor for determining cytotoxic titres, and Miss M. Croft and Miss J. A. Moore for technical assistance.

# Classically Conditioned Discrimination in the Planarian, *Dugesia dorotocephala*

by

RICHARD A. BLOCK  
JAMES V. McCONNELL

Mental Health Research Institute,  
University of Michigan,  
Ann Arbor, Michigan

Planarians have been trained in a Pavlovian way with one conditioning stimulus followed by another. Extinction trials followed, and the results indicate that the animals can differentiate between the two conditioning stimuli and respond appropriately.

SINCE Van Oye's classic study in 1920<sup>1</sup> of planarian behaviour, considerable experimental evidence<sup>2,3</sup> has suggested that platyhelminths are capable of learning even rather complex tasks, including some types of conditioned discriminations. For example, in a study by Griffard and Peirce<sup>4</sup>, planarians were trained to turn in one direction when one conditioning stimulus (light) appeared and in the opposite direction at the appearance of a second conditioning stimulus (vibration); polarized shock was the unconditioned stimulus. Jensen<sup>5</sup>, however, expressed dissatisfaction with the Griffard and Peirce experiment because their procedure did not involve reversal learning or extinction training. Our investigation was designed to overcome Jensen's objections; it consisted of four different stages of training, two involving acquisition of a conditioned response and two involving extinction.

Sixteen laboratory-hatched planarians (*Dugesia dorotocephala*) about 1 cm long were taken randomly from the stock supply of the Planarian Research Group at the Mental Health Research Institute at the University of Michigan. The parent stock had come from Buckhorn Springs, Oklahoma. The planarians were maintained at approximately 22° C throughout the experiment. They were housed individually in small glass custard cups filled with artificial pond water<sup>6</sup> and were fed brine shrimp for 1 h/week. The water was changed immediately after each feeding. The animals were maintained on a normal diurnal lighting cycle.

The training apparatus<sup>2</sup> was a block of opaque white plastic in which had been machined a square-shaped trough measuring 11 cm along each side. The trough had a semi-circular cross-sectional area of approximately 0.5 cm<sup>2</sup>. A glass tube at one corner of the trough delivered a weak jet of air which kept the water in the trough moving slowly in one direction.

The unconditioned stimulus was a pulsed direct current produced by a 6 V storage battery and delivered through a Harvard inductorium to four electrodes, one of which was mounted in each corner of the trough so as to be flush with the bottom surface. Electrodes diagonal to each other were of the same polarity, so that a planarian in the trough was always between an anode and a cathode. Conditional stimulus 2 was weak vibration produced by a 60 cycles/sec oscillator and delivered through an amplifier to a 2.5 in. speaker mounted under the plastic trough. Background illumination was dim and diffuse, being about 75 ft.-candles measured at the level of the trough. When conditioned stimulus 1 was turned on, the illumination increased to about 1,000 ft.-candles.

The intensity of the unconditioned stimulus was adjusted so that the shock presented was the minimal intensity that would always evoke a vigorous unconditioned response in the animals, which was a longitudinal contraction of the body that typically involved a turning of the anterior end of the animal towards the cathode. The intensities of the two conditioned stimuli were also adjusted so that in eight previously untrained pilot animals the response rate was less than 20 per cent to either stimulus. In this pilot study, the animals were also given exposure to the unconditioned stimulus (shock)

presented randomly to prevent any pairing of the unconditioned stimulus with either conditioned stimulus.

Two troughs mounted side by side but carefully shielded from each other were used during the experiment.

Before each day of training, six non-experimental planarians were placed in each trough for about 30 min so that there was a fresh layer of mucus on all trough surfaces. The slime-providing planarians were then removed from the troughs and the water was carefully changed. An experimental subject was then gently transported to each trough from its home aquarium by means of a large camel hair brush and allowed about 5 min to adapt to the trough before the day's trials began. A trial was begun only after the planarian had been gliding smoothly for more than 10 sec in a straight line in the direction of one of the electrodes; the planarian additionally had to be at least 2 cm from the nearest electrode when a trial began. (The speed of locomotion of planarians in these conditions is about 12 cm/min.)

During stages 1 and 3 of the experiment, each planarian was given twenty-five random presentations daily of both conditioning stimuli (1 and 2), each stimulus appearing for 4 sec. The unconditioned stimulus (shock) was presented during the final second of all twenty-five presentations of one of the two conditioned stimuli, but was never paired with the other conditioned stimulus. The minimum elapsed time between unconditioned stimuli was 60 sec. During stages 2 and 4, twenty-five daily presentations of each of the two conditioned stimuli were given as usual, but no shock was presented. A "trial" consisted of the presentation, at least 30 sec apart, of both conditioned stimulus 1 and conditioned stimulus 2, one of which might be paired with the unconditioned stimulus. Thus each animal was given twenty-five "trials"/day. The training procedure used was one found to optimize learning in several previous studies<sup>2</sup>.

For eight planarians (group LV), the light (conditioned stimulus 1) was paired with the shock during stage 1, while the vibration (conditioned stimulus 2) was paired with the shock during stage 3. For the other eight animals (group VL) the order was reversed. During stages 1 and 3, the animals were trained until they reached the criterion level of responding, then were put on extinction training. They were deemed to have reached the criterion of conditioning when, during any block of twenty-five trials, their response level to the "paired" (conditioning) stimulus exceeded 50 per cent and their response level to the "unpaired" ("neutral") stimulus was less than 15 per cent. The criterion for extinction during stages 2 and 4 was reached when the animals showed a response rate of less than 15 per cent to both stimuli during a block of twenty-five trials.

Responses made by the planarians during the initial 3 sec of the presentation of any stimulus were recorded. A response was defined as either a vigorous longitudinal contraction of the body, a turn of the anterior end of the animal through at least a 90° angle, or both. During most of the experiment, observations were made by only one experienced observer. During the first twenty-five extinction trials, however, during stages 2 and 4, the responses of four animals (two from each group) were recorded in-

dependently by two trained observers. This part of the experiment was run "blind", in that neither experimenter knew the previous history of the animals he was observing. Inter-judge reliabilities averaged more than 94 per cent.

Two animals, one from each group, were run simultaneously in the two adjacent troughs. The experiment was replicated four times; in each replication four animals (two from each group) were put through the complete experimental paradigm. No animal was discarded for any reason.

Figs. 1 and 2 present the mean frequency of responding during all four stages of training for group LV and group VL, respectively. In stage 1, using the *t* test for difference between means of matched groups (one-tailed), the mean difference between the number of responses to the "paired" as compared with the "unpaired" stimuli was statistically significant ( $P=0.01$ ) for both groups after an average of only seventy-five trials.

During stage 2 (extinction), the difference between the means was significant ( $P=0.01$ ) for the first two blocks of trials for both groups. During stage 3 (reversal), the difference between the means was significant ( $P=0.05$ ) from the very first block of trials onwards for both groups. During stage 4 (extinction), the difference between the means was significant ( $P=0.01$ ) for both groups during the first block of trials but not during the second block.

The mean number of trials to criterion in stage 1 was 213 for group LV and 173 for group VL. The mean number of trials to criterion in stage 3 was 113 for group LV and 125 for group VL. Both groups learned faster during stage 3 than during stage 1 ( $P=0.01$  for group LV;  $P=0.5$  for group VL).

Fig. 3 shows the mean frequency of responding during all stages of training for the twelve animals tested by one observer and the four animals tested "blind" during stages 2 and 4 (extinction) by two independent observers. In Fig. 3, data from groups LV and VL are thus combined. There were no significant differences between the animals scored by one observer and the animals scored blind by two independent judges.

The results of the present study support the previous findings<sup>4,6-9</sup> that planarians are capable of making a conditioned discrimination. Because, during the present experiment, each animal served as its own control, it does not seem likely that these results can be explained in terms of "sensitization" or "pseudo-conditioning". It should also be noted that significant differences were found not only during stages 1 and 3 (acquisition) but also during stages 2 and 4 (extinction), in contradistinction to earlier reports by Halas and his associates<sup>10,11</sup>. Possible explanations for the failure of these latter experimenters to find evidence for conditioning have been discussed elsewhere<sup>12</sup>.

Fig. 1. Response curves for group LV. There were twenty-five trials in each block.  $N=8$ . —●—●, Conditioning stimulus 1 (light) paired with shock; —●—●, conditioning stimulus 2 (vibration) paired with shock; —○—○, conditioning stimulus 1 (light) not paired with shock; —○—○, conditioning stimulus 2 (vibration) not paired with shock.

Fig. 2. Response curves for group VL. There were twenty-five trials in each block.  $N=8$ . —●—●, Conditioning stimulus 2 (vibration) paired with shock; —●—●, conditioning stimulus 1 (light) paired with shock; —○—○, conditioning stimulus 2 (vibration) not paired with shock; —○—○, conditioning stimulus 1 (light) not paired with shock.

Fig. 3. Response curves (circles) for a group of twelve animals judged by one observer compared with the curves (triangles) for a group of four animals judged "blind" by two independent observers during the first blocks of trials in stages 2 and 4. Solid figures denote pairing of conditioned with unconditioned stimulus. Open figures denote conditioned stimulus presented without unconditioned stimulus.

Both Kimmel and Harrell<sup>6,7</sup> and Jacobson, Horowitz and Fried<sup>9</sup> report that vibration is a more effective conditioned stimulus than is light. Because, in our experiment, the LV animals conditioned more slowly than the VL animals during stage 1, but faster than the VL animals in stage 3, our results tend to confirm these previous results.

The findings of the present study, combined with the recent report<sup>9</sup> that learning occurs in planarians given "forward" conditioning trials (in which the pairing of conditioned with unconditioned stimulus was the same as in our study) but did not occur in planarians given "backwards", "simultaneous" or "pseudo-conditioning" training, should go a long way towards answering in the affirmative the question, "Can planarians be conditioned reliably?"

## LETTERS TO THE EDITOR

## PLANETARY SCIENCE

## Dependence of Decametric Radio Emission from Jupiter on the Positions of the First Two Galilean Satellites

JOVIAN decametric radio emission is controlled by Io, the first Galilean satellite of the planet, and it has been assumed that the determining factor is the position of Io in its orbit as measured from superior geocentric conjunction<sup>1</sup> or from superior heliocentric conjunction<sup>2</sup>. It has also been shown that the probability of emission is dependent on the position of Io with respect to the plane which contains the magnetic axis of the planet<sup>2,3</sup>.

I have now analysed statistically the observations at Boulder, Colorado, of the decametric radio emission between 1961 and 1965 (refs. 4 and 5). I have sought correlations between the emission in various ranges of frequency and the position of the first three Galilean satellites of Jupiter with respect to the Sun, the Earth and the plane which contains the Jovian magnetic axis.

The radio events used in the analysis were divided into three groups according to the centre frequency. The centre frequency is the arithmetic mean of the lower and upper limits of the observed frequency range. Table 1 shows the classification chosen and the numbers of events in each class. The total number of events was 1,151. The data were stored on magnetic tapes and the search for the effects of the satellites was made by suitable computer

Fig. 1. The probability of emission as a function of the Jovicentric longitude of Io on different frequencies. —, < 15 Mc/s; ---, 15-20 Mc/s; . . . , > 20 Mc/s.

Fig. 2. Probability of emission on frequencies below 15 Mc/s as a function of the departure of Europa from SHC (—) and SGC (---).

programmes. The positions of the satellites were computed for the mid-point in time of each event.

Table 1. CLASSIFICATION OF JOVIAN RADIO EVENTS AND THE NUMBER OF EVENTS IN EACH GROUP

Group	Centre frequency	No. of events
1	< 15 Mc/s	198
2	15-20 Mc/s	579
3	21-30 Mc/s	374

Fig. 1 represents the probability of emission in three frequency ranges as a function of the Jovicentric longitude of Io. The probability of emission is increased at frequencies below 15 Mc/s when the angular departure of Io from the plane containing the magnetic axis of Jupiter is about 90 degrees. At frequencies greater than 20 Mc/s, the probability of emission reaches its maximum when Io is above the Jovian magnetic pole ( $\lambda_{III} = 200$  degrees). In fact, roughly 60 per cent of the events occur when the position of Io is between 165 and 225 degrees. The other magnetic pole at  $\lambda_{III} = 20$  degrees seems to have no influence, which may be explained by the fact that the magnetic dipole is shifted towards the northern rotational pole of Jupiter<sup>6</sup>.

Fig. 2 shows the probability of emission as a function of the angular departure of the satellite Europa from superior heliocentric conjunction (SHC) and from superior geocentric conjunction (SGC). It indicates that the probability of emission is increased at frequencies below 15 Mc/s when Europa is about 195 degrees from SHC. Statistical chi-square test shows that this peak is significant ( $P \approx 0.99$ ). The corresponding peak in the SGC-curve (about 195 degrees from SGC) has a probability of about 0.95. For Io no difference was found between the geocentric and heliocentric maxima.

The forty-one events which occurred when the angular departure of Europa from SHC was from 176 to 225 degrees were investigated in detail. Fig. 3 shows the probability of emission as a function of the longitude of Io from SHC. Evidently the influence of Io at about 240 degrees from the SHC is enhanced. When Io is about 15 degrees from the SHC, the probability of receiving radio emission on frequencies below 15 Mc/s also increases when Europa and Io are situated on opposite sides of Jupiter. Fig. 3 also shows the probability of emission as a function of the Jovicentric longitude of Europa when

Fig. 3. The probability of emission as a function of the position of Io from SHC (—) and of the Jovicentric longitude of Europa (---). Only events during which Europa was from 176 to 225 degrees from SHC on frequencies below 15 Mc/s are considered.

Europa is from 176 to 225 degrees from SHC. The probability is highest when Europa is close to the plane containing the magnetic axis of Jupiter (Jovicentric longitudes of Europa about 200 and 20 degrees).

I thank Dr Martti E. Tiuri for many helpful discussions and Dr Jorma J. Riihimaa for advice.

### Rates of Secular Variation in the North-east Atlantic

TOTAL field magnetic data have been collected by proton magnetometers towed behind ships along tracks in the north-east Atlantic during the 11 years between 1956 and 1966, and have been plotted on 1:1,000,000 plotting sheets covering Admiralty plotting sheet areas 29, 30, 41, 42, 43, 59 and 60 (Fig. 1).

In order to reduce these data to magnetic anomalies I have subtracted from the observed values a predicted regional field taken from a chart of magnetic fields in the north-eastern Atlantic drawn by Bullard, Hill and Mason<sup>1</sup>. To reduce all the data to the same epoch (1958.0) it was necessary to make a correction for secular variation.

Before choosing the rates of secular variation two assumptions were made: (a) that the rate was constant within each plotting sheet area; and (b) that the rate of

secular change remained constant over the 11 yr period. The rates of secular variation chosen were extracted from a chart of secular change for epochs 1955.0 and 1960.0 prepared by Leaton<sup>2,3</sup>. The chart was based on results from magnetic observatories on land. In the course of this work sufficient data were accumulated to make an independent check on the rate of secular variation predicted from the land observations.

A simple analysis of the collected data was made: the observed values of total field intensity, without correction for daily variation or the magnetic effect of the ship, were plotted at intervals of 10 min along tracks of the ship. Where two or more tracks crossed, the position, time, date and total field value were listed. The difference in observed values between tracks at the cross-over was divided by the time difference in years between the observations. The mean was then taken for each plotting sheet area and the probable error calculated using Peters's formula

$$r = \pm 0.8453 \frac{\sum |v|}{n\sqrt{n-1}}$$

where  $v$  is the sum of the residuals and  $n$  is the number of observations. The result should then be the mean annual rate of secular change.

In the course of this some obviously inaccurate cross-overs were found. Some errors could result from the fact that no correction was made for daily variation in the geomagnetic field which might account for  $\pm 25\gamma$  and possibly more in times of magnetic storms. In general no data on daily variation were available other than from distant land observatories and so no corrections were applied. Nor was any correction made for the magnetic effect of the ship at the magnetometer; this is dependent on course and could produce errors of  $\pm 10\gamma$ .

Errors and inaccuracies in navigation, particularly in areas of steep magnetic gradient, caused some of the bad cross-overs. Much of the area has been within the range of the Decca and Loran radio navigation station for several years, however, and later tracks should be accurate to  $\pm 1$  mile. Tracks farther offshore and out of the range of Decca and Loran, as in area 41, depended on clear skies for astrofixes and some of the tracks are probably only accurate to  $\pm 5$  miles.

Means were calculated only for the plotting sheet areas which had a sufficient number of reliable cross-overs.

The results are shown in Table 1.

Area	Lat. and long. covered	No. of cross-overs	Mean annual rate of change	Error	Previously assumed values
29	48°-54° N. 6°-21° W.	26	+20.2 $\gamma$	$\pm 5.78 \gamma$	+20 $\gamma$
42	42°-48° N. 12°-24° W.	36	+15.6 $\gamma$	$\pm 4.23 \gamma$	+15 $\gamma$
43	42°-48° N. 0°-12° W.	137	+17.1 $\gamma$	$\pm 1.34 \gamma$	+15 $\gamma$
60	36°-42° N. 6°-18° W.	38	+8.7 $\gamma$	$\pm 3.44 \gamma$	+10 $\gamma$

This is the first independent check on rates of secular variation for an oceanic area using off-shore data and the generalized values which we obtained for each plotting

Fig. 1. Map of plotting sheet areas.

sheet area agree remarkably well with those calculated from land observatory data.

### Natural Infrasonic of Five Seconds Period

BOTH infrasonic air pressure waves with periods of 4–6 sec, known as microbaroms<sup>1</sup>, and seismic ground waves or microseisms, are generated within marine cyclonic storms. This communication considers briefly the origin of microbaroms and their relationship to microseisms and describes and interprets the recently observed semi-diurnal variation of microbaroms. The general characteristics of microbaroms have been described elsewhere—for example, as summarized by Donn and Posmentier<sup>2</sup>.

Cook<sup>3</sup> suggested a line source origin in which ocean wave energy is transformed to acoustic energy at the shore when a semi-infinite train of waves is stopped abruptly. To test this hypothesis we set up a portable capacitor-microphone system at points ranging from the breaker zone on the south shore of Long Island to this laboratory, 65 km to the north. Although higher than average swell was present from an offshore hurricane, there was no significant variation in microbarom amplitude over the range involved. The observations tend to negate the surf mechanism and indicate that the infrasonic waves were coming from a region, distant or large in relation to the 65 km range.

On the basis of a case study, Donn and Posmentier<sup>2</sup> concluded that both microseisms and microbaroms were generated in the ocean water-bottom system and in the atmosphere, respectively, by the same mechanism. This conclusion is supported by the comparison of microseism and microbarom spectra in Fig. 1a which was developed from a simultaneous 45 min magnetic tape recording to both sets of signals, a playback of which is shown in Fig. 1b. The double cyclone system in Fig. 2 was the source of both microseisms and microbaroms.

The air and ground waves have remarkably similar power spectra—including relatively fine details. This was also observed for a different case by Donn and Posmentier<sup>2</sup>. Despite their simultaneous arrival, it was shown by both Cook<sup>3</sup> and Donn and Posmentier<sup>2</sup> that coupling between the ground and air waves during propagation is not possible. Ocean waves appear to be the only mechanism within the storm source capable of exciting these different phenomena with such similar characteristics. My own earlier observations of ocean waves and microseisms seemed to negate this mechanism of microseism origin and so the conclusions based on these new, cogent observations are a reversal of opinion. Posmentier<sup>4</sup> has extended the microseism theory of Longuet-Higgins<sup>5</sup> to include the oscillations of the centre of gravity of the air above standing ocean waves and has obtained amplitudes and periods of infrasonic waves close to those observed at distances of hundreds of kilometres.

In addition to the well known seasonal variation of microbaroms (low intensity in summer) from a variation in storm intensity and in upper level winds, prominent diurnal and semidiurnal changes in intensity also occur.

Existing literature (for example, Saxer<sup>6</sup>) refers only to the diurnal variations of microbaroms, but those observed here usually show a pronounced semidiurnal change when an intense marine storm exists and when the signal is not obscured by local pressure noise induced by wind. Peaks of activity are characteristically centered just after local noon and local midnight (Fig. 3). Although our tripartite

Fig. 1. a, Power spectra of microseisms and microbaroms recorded simultaneously on analogue magnetic tape and processed through a statistical analogue computer (Noratom ISAC). The scales of power on the Y axes are not equivalent. b, Analogue record of a small portion of the 45 min of signal the analyses of which are shown in Fig. 1a. Microseisms were recorded by an electronic, vertical component seismograph having a pendulum period of 15 sec; microbaroms by a capacitor microphone with the output filtered through a 1–10 sec pass band to suppress wind noise.

station for infrasonic wave detection has been in operation less than a year, it now seems that the semidiurnal oscillation variation is weak or absent from late spring to early autumn—the time when signal intensity is generally low.

The cause of the strong semidiurnal oscillation is not yet fully explained, but the 12 h periodicity with peaks close to local noon and midnight suggests an origin related to solar thermal or solar tidal effects for the following reasons. The storm sources of the microbaroms are between hundreds and one to three thousand kilometres away. Infrasonic waves from such storms must therefore follow paths that curve gently into the upper layers of the atmosphere where the temperature and wind structure may be quite different from conditions near the surface. Layers with high sound velocities because of higher temperatures and higher wind speed (in the direction of wave travel) tend to refract rays originating at the surface back to the surface. Layers of lower velocities tend to refract rays

away from the surface. The temperature increase in the upper stratosphere and lower mesosphere produces an increase in sound speed of about 30 to 35 m/sec. Although

Fig. 2. Weather chart of the western North Atlantic Ocean showing the storm pattern related to the microseisms and microbaroms of Fig. 1. Palisades (Lamont Geological Observatory location) is shown at "P".

Fig. 3. A portion of the 24 h record of infrasonic waves recorded on January 2-3, 1967, at the Lamont Geological Observatory (Palisades, NY) with the use of Globe microphonic pressure transducers. About 17 min of each line, which contain 60 min, are shown in the copy. Timing marks are made at intervals of 1 min. (EST is 75° meridian time.)

this effect produces a "sound channel" between the surface and about 50 km, no semidiurnal or diurnal variability of the type required is known. Conceivably a rising and falling of the reflecting layer may occur from solar and auroral heating, and this may vary the positions of reflection and produce the observed effect. Preliminary results indicate that wind variations are the more important factor.

Tidal wind components show a pronounced semidiurnal clockwise rotation in the northern hemisphere<sup>7</sup>. At an elevation of about 100 km the tidal component is reported to have a speed of about 30 m/sec. The normal track and development of cyclones are such that the most common infrasonic signal of storm origin arrives from a direction north-east to east-north-east of Palisades. According to Stolov<sup>7</sup>, winds at about 100 km come from a north-easterly direction at about 0100-0200 and 1300-1400 local solar time. The 6 h differential in the ambient wind speed is thus 60 m/sec. The mean zonal winds above the tropopause increase from about 20 to about 70 m/sec, and so the tidal wind effect would seem, in a preliminary examination, to be of significance in producing the semidiurnal oscillation.

On at least two occasions of strong semidiurnal oscillations the signal, at times of wave amplitude maxima, arrived from well developed storms to the north-east of Palisades as determined by our tripartite station. But at the times of minima, the signals arrived from the north-west. At these times, intense storms were present off the west coast of Canada some 3,000 or more kilometres away. The tidal wind component would also be from the west at these times. The semidiurnal variation is under continuing investigation. It should be noted that this discussion refers to storm generating areas at least hundreds of kilometres from the recording station. When they are quite close to the station, microbarom activity is continuously high with no obvious time variations.

### Palaeomagnetism of Atlantic Islands: Fernando Noroña

BECAUSE of their role in testing the crustal spreading hypothesis<sup>1</sup> the ages of Atlantic islands have assumed a prime importance<sup>2</sup>. Conventional geological methods are not usually applicable to studies of oceanic islands, because of the general lack of stratigraphically useful fossils and the dominantly volcanic environment. Palaeomagnetic methods, as pioneered by Einarsson<sup>3</sup>, however, can provide valuable stratigraphic indices in volcanic regions. In addition, if defined from a time span sufficient to average out secular variation<sup>4</sup>, palaeomagnetic poles can provide age estimates, because with increasing age they have occupied positions at increasing angular distances from the present geographic pole. Palaeomagnetic surveys are forming the bases of diverse studies of Atlantic islands. This is the third in a series of reports<sup>5,6</sup>, in which the palaeomagnetic poles resulting from these surveys are reported.

Fernando Noroña (Fig. 1) is an island of 18.4 km<sup>2</sup> area on the geomagnetic equator, at latitude 3° 50' S. and longitude 32° 26' W., approximately 345 km from the

north-east coast of Brazil. Almeida<sup>7</sup> has carried out a detailed geological survey, including extensive chemical and petrological analyses, to define the volcanic history of the island. Two principal stratigraphic units are defined (Fig. 1). The older Remédios formation contains no effusive rocks, but is highly diversified, consisting of various pyroclastic rocks cut by plugs of alkali basalt, essexite porphyry, trachyte, large phonolite domes, and dykes of very variable petrological type. Above an irregular unconformity, the younger Quixaba formation consists of ankaramite lavas and intercalated pyroclastics. The physiography is dominated by the phonolite domes, with "Pico" being regarded as "the most striking landmark in the South Atlantic Ocean"<sup>8</sup>. In common with outcrops on most oceanic islands, no sound age estimates are possible. Almeida limits speculation to the following: "The age is certainly pre-glacial, and considerations about the age of volcanism in the Atlantic Ocean seem to indicate that it ought not to be older than Senonian (Upper Cretaceous)"<sup>9</sup>.

Wilson<sup>10</sup> noted that a pre-continental drift configuration would involve virtual superimposition of the magmatic sources of the islands of the Gulf of Guinea (Fernando Po, Principe, Annabon) and Fernando Noroña, and that the

available geochemical data are consistent with such a similarity.

At least four cores were drilled from each of twenty-eight separate bodies which represent most of the outcrops on the island. Sample locations are shown in Fig. 1. The cores, of 2.5 cm diameter and average length 12 cm, were oriented in geographic co-ordinates while still attached to outcrop. An astatic magnetometer and alternating field demagnetizing unit were used to determine the natural remanent magnetism (NRM) of each specimen. The results for each body are given in Table 1. Polished thin sections from all specimens have been examined using a Reichert 'Zetopan-pol' reflexion microscope at  $\times 1,200$  under oil, and Curie points have been measured in each specimen. Full results will be reported elsewhere, but it can be stated here that there is no reason to believe that the NRM measured is not caused dominantly by the ambient magnetic field during the initial cooling of the bodies sampled, although the NRM in four bodies is insufficiently well defined<sup>11</sup> to be included in group statistical analyses<sup>12</sup>.

The virtual geomagnetic poles (or surface expressions of the hypothetical geocentric dipoles which would give rise to the observed NRM) for each body are shown in

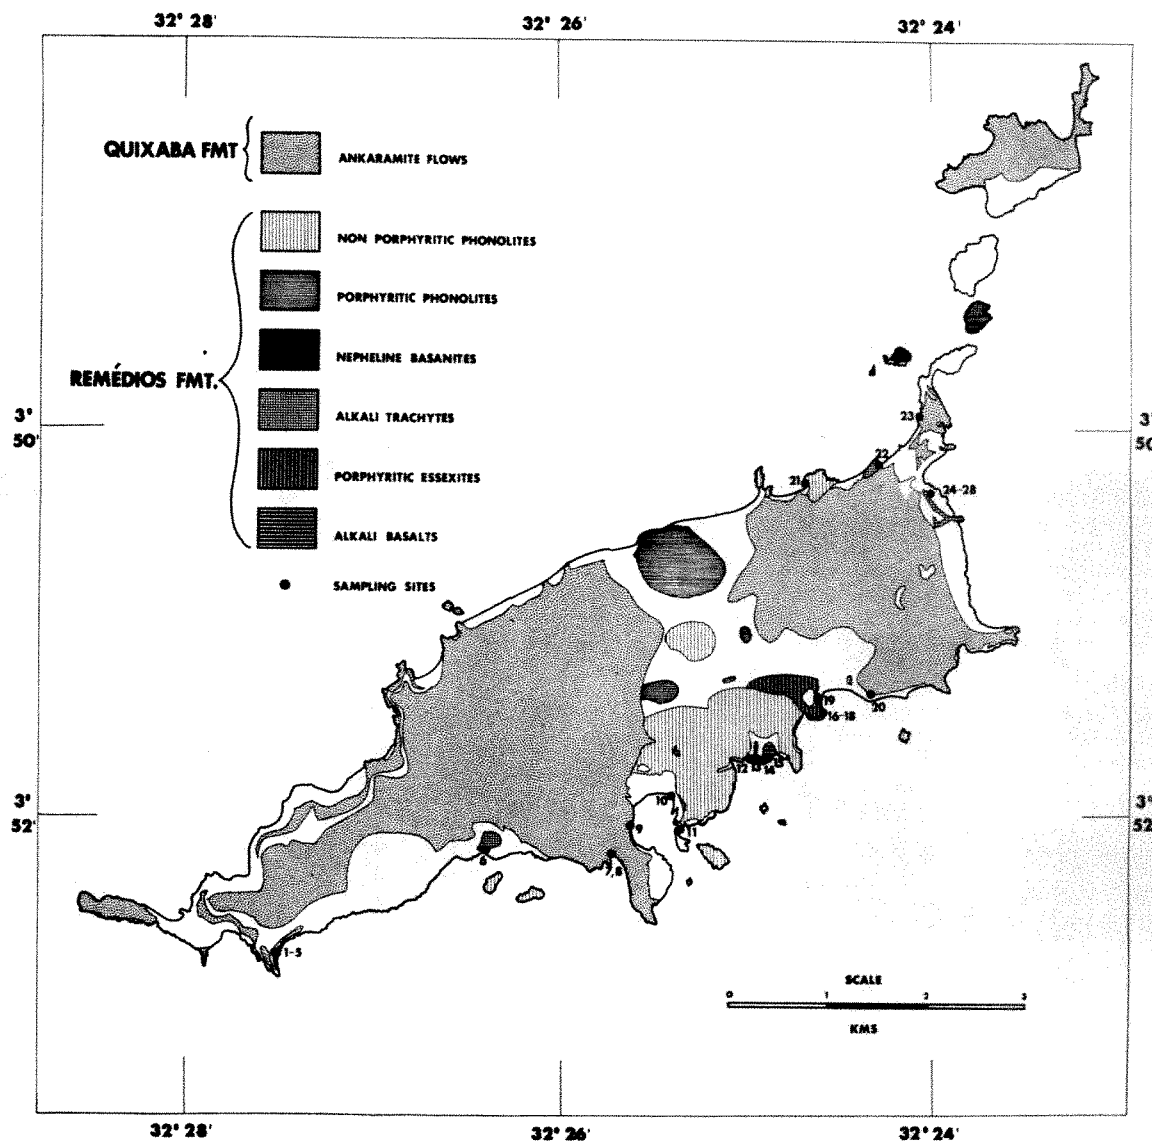

Fig. 1. Geological map of Fernando Noroña, after Almeida<sup>7</sup>. Sample sites are shown as solid circles, with numbers corresponding to the data presented in Table 1.

Fig. 2. Virtual geomagnetic poles for each of the twenty-four units which provide data of sufficient precision. Results from the older Remédios formation are shown as circles; those from the younger Quixaba formation are shown as squares. A cross within the circle or square signifies normal polarity; a dot within the circle or square signifies reversed polarity; (reversed or southern hemisphere poles are transposed to the northern hemisphere). The mean of all the virtual geomagnetic poles (or palaeomagnetic pole) is shown as a star. The dotted oval is the 95 per cent confidence oval of the palaeomagnetic pole. The position of the present geomagnetic pole is shown by a heavy cross.

Symbols as in Table 1, except here unit vector per body is applied. In addition *B* is the number of bodies sampled. Note that in some of the above cases *k*<sub>max</sub> < *k*<sub>100</sub>. This is not a computational error: *k*<sub>max</sub> results from unit vector being applied to each 'least scatter' (*k*<sub>max</sub>) body as in Table 1, and there is no reason why this must be > *k*<sub>100</sub> or *k*<sub>200</sub>.

Fig. 2. Table 2 shows the results of combining the data to obtain the palaeomagnetic poles for both formations, and for the entire survey. The palaeomagnetic pole for the entire survey is shown in Fig. 2, together with the 95 per cent confidence oval. Polarity variations in both formations suggest a sufficient time span for probable cancellation of short period or secular variations<sup>13</sup>. Fig. 2 clearly shows that the palaeomagnetic pole for Fernando Noroïha is not significantly different from that caused by the present axial dipole. Comparison of this fact with much independent data strongly suggests that Fernando Noroïha does not exceed Miocene age in outcrop. For example, Doell and Cox<sup>14</sup> suggest that post-Miocene geomagnetic poles are not on average divergent for the present geographic pole; and Irving<sup>15</sup> shows a clear difference between Lower Tertiary palaeomagnetic poles and the present geographic pole.

This suggested age limitation for Fernando Noroïha would clearly invalidate any comparison of the island surface with the islands of the Gulf of Guinea in terms of any pre-drift configuration, for even if continental drift is considered proved the Gulf of Guinea and north-eastern Brazil could not be envisaged as being sufficiently close to yield the same magmatic sources for outcrops of the respective islands during the Upper Tertiary.

We thank the NERC for support and Professor R. G. Mason for continued support and encouragement.

### Additional Theory of Origin of Fiamme in Ignimbrites

THE pantelleritic Quaternary volcano Fantale (lat. 8° 58' N., long. 39° 54' E.) is situated at the northern end of the main Ethiopian rift valley. During a field excursion to this volcano, we made a brief examination of a recent ignimbrite. This pale green ash flow, which was probably erupted in association with the formation

of the Fantale Caldera<sup>1</sup>, is particularly rich in fiamme. Fiamme are flattened, black, glassy inclusions with flame-like cross sections. These are usually considered to have formed by the collapse of included molten pumice under the load of the overlying portions of the pyroclastic flow<sup>2</sup>. As we shall show, it seems unlikely that the fiamme in the Fantale ignimbrite originated in this way; the purpose of this communication is to suggest an alternative origin.

The Fantale ignimbrite covers much of the plain of Matahara surrounding the volcano to the south and west, and is also present in places on the slopes of the mountain. As the unit is traced uphill towards the caldera, however, the ignimbrite becomes much less extensive. The thickness varies considerably because of the irregular topography of the volcano before the eruption. Nevertheless, it can be shown that the unit is thinner (0.3–2 m) on the sloping flanks of the volcano, and very much thicker on the surrounding Matahara Plain (about 20 m). A striking feature is the absence of an air-fall pumice deposit either below or above the welded tuff. Wherever erosion or faulting allows examination of its whole thickness, the ignimbrite is revealed as being completely welded from top to bottom, in the more extreme cases to a hard flinty rock.

Fiamme are present throughout the flow, and although not regularly distributed they are definitely not localized in the lower parts of the unit. Even when the ignimbrite is only 30 cm thick, well developed, severely flattened fiamme are present. Under the microscope these show no evidence of a collapsed pumice origin, but instead many are filled with spherical bubbles. It is striking that the highly flattened inclusions contain generally undeformed vesicles. Similar fiamme are also present in the topmost part of the flow on the Matahara Plain. In the absence of any thick overlying tuff therefore it is unlikely that the fiamme in many parts of this unit could have originated by the collapse of included molten pumice. This is particularly obvious because the presence of euhedral uncorroded anorthoclase phenocrysts suggests that unusually high eruptive temperatures were not involved.

It is suggested that on eruption the Fantale ignimbrite was composed of the usual gas phase loaded with shards, crystals and lumps of molten pumice. In addition it contained abundant inclusions of non-vesiculated, gas-rich molten glass. These glassy inclusions must have been very fluid on eruption, probably because of their particularly high gas content<sup>3</sup>. Thus on deposition they became very flattened, even when the weight of the overlying ignimbrite was very small. After deposition and flattening, the inclusions at last began to vesiculate<sup>4</sup>, forming the spherical bubbles.

It should be stressed that we do not suggest that fiamme in "normal" ignimbrites originated in this way. The mode of origin outlined here, however, must be considered when fiamme are found in extremely thin ignimbritic units.

Further work on this striking unit is in progress. Studies of present day ignimbrites in Alaska<sup>5</sup> indicate that "normal" ash flow deposits do not show the extreme welding and flattening in the absence of any overload, as is visible at Fantale. Particular efforts are being made to understand this feature. Other workers interested in this problem are invited to write to us; we shall be pleased

to supply typical thin sections and other information in exchange for comparable material.

## Origin of the Keuper Salt in Britain

EXPLORATION for hydrocarbons in the southern North Sea has shown that over a large part of it the Mesozoic rocks are underlain by Upper Permian (Zechstein), containing thick salt layers which have reacted to the overburden load by developing a wide range of halokinetic structures, from salt pillows to diapiric salt plugs<sup>1,2</sup>. Some of the plugs penetrate the overlying beds to levels high in the Mesozoic and Tertiary rocks, and in some cases approach the level of the sea floor. Seismic profiles show sharp variations in stratal thickness associated with the plugs, commonly indicating a history of movement from at least Lower Jurassic times onwards.

It has been suggested that certain anomalous sedimentary features of eastern England may be related to the erosion of Triassic rocks in North Sea salt plugs<sup>1</sup>. Thus the Albian Red Chalk development requires a source of fine-grained ferruginous detritus which could well be from this source, and the two Cretaceous ironstones of east Lincolnshire could reflect erosion of ferruginous Trias. To these may perhaps be added the unique red-bed facies of the Upper Rhaetic of north Lincolnshire and south Yorkshire<sup>3</sup>.

The salt movements can, however, be shown in some cases to have affected beds as early as the Middle Triassic Muschelkalk, and this has suggested an explanation for the problem of the Keuper salt beds in Britain. It has long seemed to us that the great bulk of sodium chloride in the Keuper associated with minimal quantities of calcium sulphate and other salts precludes direct origin by evaporation of sea water; it must have been derived from pre-existing salt beds. The suggestion that the Keuper salt was derived from normal sea waters, which precipitated dolomite and gypsum in crossing "a broad shelf far to the south-east" (unpublished work of W. B. Evans) is negated by the evidence of Keuper development available to us. No such massive—or even significant—quantities of Keuper dolomite or gypsum are known in the relevant area.

Certain of the north-west German Zechstein salt plugs are known to have reached the diapiric stage in Keuper times<sup>4</sup>, and the same may be true of some of the plugs on the western side of the North Sea. On reaching the surface they would be leached by the rivers or lakes of the Triassic landscape, just as the desert rivers of South Persia are now leaching the emergent plugs of Cambrian salt. A supply of sodium chloride brine would thus become available, almost free of sulphates and carbonates, for subsequent redeposition by evaporation in the deeper parts of an inland basin. Such may be the source for the Keuper salt beds in Britain.

The main British Keuper salt beds are located in the deep Triassic basins of western England, in Lancashire, Cheshire, Worcestershire, Somerset and the Isle of Man.

This limitation may be a function of the basin type, involving rapid subsidence, with consequent heavy deposition and with relatively steep flanks which may be in part fault controlled. Evidence has recently been adduced to show that much of this western area was topographically low in Triassic times<sup>5</sup>. Alternatively, but in our view less likely, the westerly location of the thick salt beds might indicate that the source was more local, and that the Irish Sea basin is not only an important Triassic feature<sup>6,7</sup> but includes Permian evaporites thick enough to have developed piercement salt plugs which supplied separated halite for the Keuper basins.

Salt beds with only very small quantities of associated gypsum or anhydrite which occur in the Keuper of the North Sea and north-west Germany may also, it is suggested, owe their origin to the process described here.

## PHYSICS

### Vacuum Arc Voltage

IN an investigation of the cathode mechanism of the vacuum arc, in a vacuum of  $10^{-5}$  torr, arc voltages were recorded for forty-one different cathode metals. Oscillographic measurements were made at the minimum stable arcing current over a period of 20 sec; values varied from 5 to 25 V. Each arcing voltage consisted of a broad band of noise 2–3 V in width with a well defined lower edge  $V_L$ . The quantity  $V_L$  was measured for all forty-one elements and used as a parameter for correlation with the solid state properties of the cathode.

It is suggested that a connexion exists between arcing voltage and the plasma frequency  $\omega_p$  of the electrons in the cathode metal. Should there be a direct connexion, such that

$$eV_L = \frac{h\omega_p}{2\pi} = \frac{h}{2\pi} \sqrt{\frac{sN\rho e^2}{Wm\epsilon_0}} \text{ joules} \quad (1)$$

using M.K.S. units, so

$$V_L = \frac{h}{2\pi} \sqrt{\frac{sN\rho}{Wm\epsilon_0}} \text{ volts} \quad (2)$$

where  $\frac{h\omega_p}{2\pi}$  is the plasma oscillation energy of the electrons

in the solid ( $h$  is Planck's constant);  $\omega_p^2 = \frac{ne^2}{m\epsilon_0}$  gives the

plasma frequency of the electrons in the solid metal cathode (M.K.S.);  $n$  = effective free electron density in the metal (per  $m^3$ );  $m$  = mass of electron in kg;  $e$  = charge of electron;  $N$  = Avogadro's number;  $\rho$  = density of metal (solid state),  $kg/m^3$ ;  $W$  = atomic weight;  $s$  = number of electrons/atom contributing towards  $n$ ;  $\epsilon_0$  = permittivity of free space.

Then the experimental results should give information on  $s$ —the number of electrons/atom contributing towards the plasma oscillations in the metal.

Ga	10.0	1.43	Ta	20-23.0	5.2-6.9			
In	9.5	1.71						

The analysis was carried out using equations (1) and (2) and results are tabulated in Table 1.

If the connexion between  $s$  and the valence is not a coincidence, one would expect the best fit for elements which react chemically with a unique valency, valency electrons being clearly differentiated in their energy from those in inner shells. On the whole, the best fit between  $s$  and valence is found for the alkaline and rare earths and aluminium, in which this requirement is fulfilled.

## THE SOLID STATE

### Radiophotoluminescence of Biphenyl in Methylcyclohexane Glass

It is known that the recombination of positive and negative species trapped in rigid matrices during gamma-irradiation at 77° K leads to the emission of light. This recombination, and the subsequent luminescence, can be induced either by warming the sample to certain characteristic temperatures (radiothermoluminescence, RTL) or by illuminating it at 77° K with light of a suitable wavelength (radiophotoluminescence, RPL). In previous work<sup>1</sup> it was shown that in methylcyclohexane glass containing aromatic compounds two peaks of RTL are observed, one of which could be ascribed to the recombination of cations with electrons trapped in the glass and the other to the recombination of cations with negative ions. The emission spectra observed correspond to the fluorescence and phosphorescence spectra of the dissolved aromatic compounds, the phosphorescence spectrum being enhanced in comparison with photoluminescence. We have found that identical emission spectra could be obtained by illuminating the sample with infra-red light (1.2-1.8 $\mu$ ), though our results have not yet been published.

Fig. 1. Decay of RPL. Time, 1 division = 2 sec.

Fig. 2. RPL excitation spectra of biphenyl in methylcyclohexane. Dotted curve,  $10^{-4}$  molar; dashed curve,  $10^{-3}$  molar; full curve,  $10^{-2}$  molar biphenyl.

We have now obtained a complete RPL excitation spectrum of gamma-irradiated glassy solutions of biphenyl in methylcyclohexane, between 360 m $\mu$  and 2.3 $\mu$ .

In this work the solutions were bubbled with helium in order to remove possible traces of carbon dioxide, degassed by the freeze-pump-thaw technique, and then irradiated at 77° K with a cobalt-60 source to a dose of about 60 krad at a dose rate of about 80 rad/min. The sample, placed in liquid nitrogen, was then illuminated with light from a xenon arc, through a monochromator. Slit widths were adjusted at each wavelength to give a constant light flux, as determined by calibration with a thermopile. An electro-mechanical shutter protected the photomultiplier used to detect the luminescence while the exciting light was on (1 sec); it opened 1 sec after the end of excitation. The photomultiplier output was displayed on an oscilloscope and photographed. In this way we obtained the decay of the long-lived component of the luminescence, as is shown in Fig. 1.

The plot of luminescence intensities, at a constant time after the end of illumination, against wavenumbers of the exciting light gave the spectra shown in Fig. 2. The dotted curve, with maxima at  $6.25 \times 10^3$ ,  $7.4 \times 10^3$ ,  $9.1 \times 10^3$   $\text{cm}^{-1}$  and  $10 \times 10^3$   $\text{cm}^{-1}$ , was obtained with a  $10^{-4}$  molar solution of biphenyl. It is similar to the absorption spectra observed by different authors<sup>2,3</sup> for electrons trapped in hydrocarbon matrices. The full curve was obtained with a  $10^{-2}$  molar solution of biphenyl. The trapped electron bands in the infra-red are practically absent, and the bands observed at 0.650, 0.405, 0.393 and 0.380 $\mu$  ( $15 \times 10^3$ ,  $24.6 \times 10^3$ ,  $25.4 \times 10^3$  and  $26.3 \times 10^3$   $\text{cm}^{-1}$ ) coincide with the absorption spectrum of the biphenyl anion<sup>4</sup>:  $\lambda_{\text{max}} = 0.660$ , 0.410, 0.395 and 0.380 $\mu$ . For  $10^{-3}$  molar solutions of biphenyl, both anion and trapped electron bands appear in the excitation spectrum (dashed curve).

The observed effect of solute concentration on the excitation spectrum indicates competition between traps and biphenyl molecules for electrons released during gamma-irradiation. A similar concentration effect was observed by Guarino and Hamill<sup>5</sup> for the absorption spectra of irradiated solutions of biphenyl in 2-methylpentene-1.

From this concentration dependence it can be deduced that an electron can migrate up to a distance of 55 Å from the parent cation with practically no chance of being trapped in the matrix (only biphenyl ion bands are present in the RPL excitation spectrum of a  $10^{-2}$  molar solution), but that within a distance of 250 Å trapping in the matrix is nearly 100 per cent (no biphenyl ion

bands in  $10^{-4}$  molar solution), the average trapping distance being about 120 Å, which agrees with results obtained by other techniques.

From the luminescence decay a lifetime of  $4.05 \pm 0.05$  sec has been determined for the long-lived excited state. This value is in good agreement with the lifetime of biphenyl phosphorescence, 4.0 sec, measured by Azumi and McGlynn<sup>6</sup> at the same temperature.

When infra-red light was used, the protection of the photomultiplier during excitation was unnecessary, and both fluorescence and phosphorescence could be recorded simultaneously in the course of excitation by McClain and Albrecht's technique<sup>7</sup> of chopping the exciting light. McClain and Albrecht analysed the kinetics of the fluorescence and phosphorescence of tetramethyl *p*-phenylenediamine brought about by infra-red light after photo-ionization in glassy 3-methylpentane and showed that the enhancement of phosphorescence could be explained in this case by a direct formation of both triplet and singlet states from a common intermediate formed in the course of the recombination. Their relation seems also to apply to the RPL of biphenyl in methylcyclohexane glass; the lifetime for biphenyl phosphorescence deduced in this way,  $4.5 \pm 0.5$  sec, is in fairly good agreement with the value given by Azumi and McGlynn.

Analogous experiments with other aromatic hydrocarbons are in progress.

## Origin of the Luminescence in Natural Zircon

NATURAL zircons generally luminesce yellow or orange under ultra-violet light<sup>1,2</sup>. The luminescence is not caused by the tetravalent uranium responsible for the absorption spectra of zircon<sup>1,3</sup>. Because there have been speculations on the origin of the luminescence, I have studied several zircons which gave a yellow luminescence and I have found that there are at least two main types of luminescent

centres in zircon. The varying proportions of these centres give the differences in the colour of the luminescence.

The luminescence spectrum of a zircon crystal which has both types of centres is shown in Fig. 1.

Type 1 centres are most probably trivalent europium,  $\text{Eu}^{3+}$  ions. They give the two groups of lines at 4800 Å and 5800 Å, and these correspond to the transitions  $^5\text{D}_2 \rightarrow ^7\text{F}_2$  and  $^5\text{D}_1 \rightarrow ^7\text{F}_3$ , respectively, of the  $4f^6$  configuration of  $\text{Eu}^{3+}$  in  $\text{LaCl}_3$  (ref. 4). The number of lines in each group is about that expected from selection rules. No other rare earth ion could be responsible because different host lattices have only a very small effect on the transition energies of these ions. Only the intensities of the different transitions are affected by the host lattice. Europium is known to have a very high luminescence efficiency and hence only a small amount is required to give the weak luminescence observed.

Europium lines were found in most of the luminescent spectra observed. Some New Zealand zircon sands gave weak lines while a white zircon gemstone from Siam gave strong europium lines but no trace of the type II centre. Type II centres appear to be colour centres induced by the radioactive decay of the uranium and thorium present. Their luminescent spectrum is a broad band centred around 6000 Å. (In Fig. 1 the structure around 6500 Å is caused by absorption of the luminescence by  $\text{U}^{4+}$  ions.) The zircons giving this luminescence are coloured a yellow-brown, and on heating to about 1,000°C they become clear and the broad band goes from the luminescent spectrum. This type of heat treatment is often applied to coloured zircons to produce the clear gemstone variety<sup>1</sup>.

Zircons which have been subjected to intense radiation become red-brown and have marked colour centres<sup>5</sup>. No luminescence, however, is known from these, though there may be some infra-red luminescence.

I thank I. N. Douglas for his assistance and D. R. Hutton for supplying the zircon samples.

## Photo-annealing of Chemical Radiation Damage

ANNEALING of the chemical effects of nuclear recoil in solid substances by ionizing radiations<sup>1</sup> and by ultra-violet<sup>2</sup> and visible<sup>3</sup> light is well known. In the case of chemical radiation damage, evidence for the existence of radiation annealing, necessarily indirect, is provided by the observation that the rate of damage generation decreases with increase in the radiation dose. The effect is particularly pronounced in lead nitrate for which the steady state nitrite yield under gamma-irradiation, for example, is only about 2 per cent<sup>4,5</sup>. There is no record of photo-annealing of chemical radiation damage in the literature. We have observed the recombination of damage fragments in lead nitrate by light in the visible region.

The experiments were conducted on lead nitrate crystals sieved to between 85 and 100 mesh, vacuum dried and irradiated with a dose of 50 Mrads with cobalt-60 gamma-rays at the dose rate of 1.5 Mrads/h. Samples (100–150 mg) of the irradiated crystals, in thin layers, were illumin-

Fig. 1. Densitometer trace from an 'Astra III' plate of the luminescence spectra of a zircon crystal at room temperature. Taken on a Hilger quartz spectrograph.

Fig. 1. Photo-annealing of chemical radiation damage in lead nitrate.

Fig. 2. Dependence of photo-annealing on the light frequency.

ated at 50 cm distance with light from a 200 W tungsten filament lamp condensed by a 10 cm diameter lens system. Care was taken to ensure that the samples did not get heated up during the illumination. The same procedure as that previously described was used for determining the damaged nitrite<sup>4</sup>. Typical plots of the nitrite concentration in p.p.m. versus the time of illumination are given in Fig. 1. The plots lie on a straight line which implies a monomolecular recombination process.

The dependence of the annealing on light frequency, in the visible range, was investigated by exposing samples of the irradiated crystals to different narrow wavebands obtained by using monochromatic coloured glass filters and the same source of light as before. The effective mean frequency of the light bands was determined by standard optical methods. Fig. 2 records a set of data for an exposure of 360 h. It is seen that the annealing increases linearly with increase in the effective mean frequency of the light. Extrapolation to the zero value of nitrite

annealed gives a threshold frequency for annealing, namely,  $42 \times 10^{13} \text{ sec}^{-1}$  (wavelength, 7140 Å) corresponding to an energy of 1.74 eV. The fact that the recovery is caused by light shows that it occurs by an electronic process.

Experiments with ordinary lead nitrate showed that the salt is not susceptible to photolysis by visible light.

We thank the Bhabha Atomic Research Centre, Bombay, for assistance with the irradiations.

## CHEMISTRY

### Structure of Phycoerythrobilin and Phycocyanobilin

DEGRADATIVE work on the phycobilin prosthetic groups of the algal biliproteins (phycoerythrins and phycocyanins) has been hampered by the difficulties involved in splitting off these prosthetic groups in native form and isolating them in sufficiently high yields for classical degradation and analysis. These difficulties have now been avoided by using the chromic acid micro-degradation technique recently refined for the study of aplysiocyanin<sup>1</sup>, the defence pigment of the sea hare. This technique may be used with as little as 100  $\mu\text{g}$  of bilin and is not affected by the presence of protein (Rüdiger and Klose, W., unpublished), thus enabling direct degradation of the phycobilins while still attached to the proteins. This development, together with the improved resolution of the chromatographic techniques used, has led to the identification of side chain groupings not previously detected in these prosthetic groups.

Degradation of the phycobilins *in situ* on the biliproteins and release of the resulting imides was achieved by mixing 2–4 mg of the purified biliprotein<sup>2</sup> in water (0.2 ml.) with acetone (0.1 ml.) and 1 per cent chromic acid in 2 normal sulphuric acid (0.2 ml.) and heating at 90–100° C for 1 h. Free bilins were degraded as described for aplysiocyanin<sup>1</sup>. The imide degradation products were extracted into ether (0.2 ml.) and identified by thin-layer chromatography<sup>1</sup>. The identifications were verified by co-chromatography with authentic imide samples.

*R*-phycoerythrin, *C*-phycoerythrin, phycoerythrobilin (the bilin isolated after controlled acid hydrolysis of phycoerythrins<sup>3</sup>) and "purple pigment" (the closely related pigment released from phycoerythrins after prolonged refluxing with methanol<sup>4</sup>) all yielded the imides 1, 2 and 3 on oxidation. Phycoerythrobilin and "purple pigment" both contain two free carboxyl groups<sup>3,4</sup> suggesting that they each contain two rings corresponding to 1. Aplysiocyanin, which contains one free and one methylated carboxyl group, gave the imides 1, 2, 3 and the methyl ester of 1 on oxidation<sup>1</sup>. After methylation of their free carboxyl groups, "purple pigment" and aplysiocyanin became indistinguishable by thin-layer chromatography on silica gel in a range of solvent systems, and had identical ultra-violet and visible spectra as free base, hydrochloride and zinc complex. As reported previously for "purple pigment"<sup>4</sup>, aplysiocyanin was converted by cold 10 normal hydrochloric acid first to a rhodin spectrally identical with phycoerythrobilin, and then to a urobilin which formed a chloroform-insoluble adduct with cysteine. The "purple pigment" (in common with phycoerythrobilin and phycoerythrin) gives a transient deep blue colour in alkali, which is also characteristic of aplysiocyanin<sup>1</sup>. This evidence strongly suggests that the "purple pigment" is the unesterified form of aplysiocyanin. Structure 5 is therefore proposed for the "purple pigment", since the structure previously proposed for aplysiocyanin<sup>1</sup> is represented by the mono methyl ester of 5, with *R* representing a hydroxyl group. The assignment of this hydroxyl group was tentative, however<sup>1</sup>, and some recent results (Rüdiger and Ó Carra, unpublished) cast further doubt on it, suggesting that *R* represents a hydrogen atom.

Phycoerythrobilin rather than the "purple pigment" appears to be the native prosthetic group of phycoerythrins<sup>3,4</sup>. The oxidative degradation shows that both compounds have identical side-chains, and as the two are readily interconvertible<sup>4</sup> they must be very closely related.

Oxidation of *C*-phycoerythrin yielded the imides 1, 2 and 4. The same products were obtained on oxidation of phycobilin 630, the bilin isolated after careful acid hydrolysis of phycoerythrin<sup>5</sup>, and of the "blue pigment" released by prolonged refluxing of phycoerythrin in methanol<sup>4</sup>. Both these isolated bilins were also found to contain two acidic side-chains, and because the phycoerythrin chromophore is intermediate between the verdin and violin types<sup>6</sup>, the conjugation must extend through

all four rings, but with one ring incompletely conjugated. Structure 6 is consistent with all these data.

Principally on the basis of nuclear magnetic resonance and mass spectral data, Cole *et al.*<sup>6</sup> have recently proposed the same structure for the "blue pigment" which they termed phycocyanobilin. The term phycocyanobilin, however, is properly applied to the native prosthetic group and it remains to be established whether the "blue pigment" or phycobilin 630 should be regarded as such. Present evidence favours phycobilin 630 (refs. 4 and 5). The precise basis of the spectral differences between these two pigments<sup>4</sup> also remains to be elucidated.

Crespi *et al.*<sup>7</sup> have also recently proposed a structure for the "blue pigment". It is similar to 6 as regards the side-chains, but contains one double bond less in the conjugated system. We consider that this is incompatible with some of the properties of the "blue pigment", in particular its facile isomerization in alkali to mesobiliverdin<sup>8</sup> and the presence of a basic pyrroline ( $-N=$ ) group in its conjugated system<sup>4</sup>.

## Photodissociation of Nitroso Dimers

Most C-nitroso compounds in the crystalline state exist as colourless dimers, though the monomers, often formed by dissociation in solution, are green or blue<sup>1-3</sup>. Heating solutions of the nitroso compounds also shifts the equilibrium so that formation of monomers is enhanced.

We have observed that solutions of some nitroso compounds which are colourless become green or blue on irradiation with ultra-violet light. On removal of the light the colour fades. This photochromic effect may be repeated many times. The colour produced by irradiation is identical to that produced by heating, and apparently is due to the formation of the monomer species.

Dimeric 3-methyl-3-nitrosobutan-2-one (I) (ref. 4) when dissolved in ethanol, chloroform, methylene chloride, or benzene yields colourless solutions. These solutions on irradiation at or below room temperature with ultra-violet light, become blue and show a maximum at 6860 Å. The same absorption curve is obtained by heating without irradiation.

Solutions of (I), in a thermostated cell, were irradiated with the unfiltered light from a high-pressure mercury lamp and the disappearance in the dark of the 6860 Å band produced by the irradiation was followed with time. The

kinetics of the fading reaction, which we believe to be the rate of dimerization, were of second order. If we assume an extinction value of 20 at 6860 Å, an approximation which appears reasonable<sup>5</sup>, the estimated respective rates of decay in ethanol and methylene chloride at -25° C were  $12.1 \times 10^{-2}$  and  $3.7 \times 10^{-2}$  l. mole<sup>-1</sup> sec<sup>-1</sup> (ref. 5).

It was also noted that in the infra-red region, irradiation caused a decrease in the intensity of the 1289 cm<sup>-1</sup> band, and formation of a new band at 1561 cm<sup>-1</sup>. On removal of the light the original absorption curve was obtained. The same respective effects were obtained by warming and cooling the same solution. Dimeric C-nitroso compounds have been reported to have an absorption in the region from 1430 to 1000 cm<sup>-1</sup>, and the monomeric form in the region from 1650 to 1495 cm<sup>-1</sup> (ref. 6).

1,4-Dichloro-1,4-dinitrosocyclohexane exists in two stable forms as a solid. The blue solid has been assigned structure (IIa) and the white solid structure (IIb) (refs. 2-7). Compound (IIb) yields a colourless solution, which on warming becomes blue because of the formation of (IIc). Irradiation of the colourless solution with ultra-violet light also produced the same blue colour which faded in the dark. At -26.3° C, the fading rate in methylene chloride measured at 6550 Å was  $0.9 \times 10^{-5}$  sec<sup>-1</sup>, and followed first order kinetics.

The formation of free radicals on irradiation of C-nitroso compounds with ultra-violet and visible light has been reported recently<sup>8-10</sup>. The relationship of this reaction to the dissociation effect observed is not clear at this time.

We have observed the production of a blue or green colour by irradiation of colourless solutions of other tertiary, secondary, and primary nitroso compounds. The kinetics of the dissociation of C-nitroso compounds have been reported<sup>11-15</sup>. By irradiating and following the colour fading rates at several temperatures we are currently investigating the kinetics of the association reaction.

## IMMUNOLOGY

### Effect of Surfactants on Antigen-Antibody Reactions

In our laboratories bentonite flocculation tests<sup>1</sup> are generally used for the titration of antigens and antisera. To reduce non-specific reactions, surfactants are sometimes added to the bentonite suspensions. Recently a report has appeared suggesting that the surfactants have an adverse effect on biological systems<sup>2</sup>. We therefore decided to examine the effect of surfactants on antigen-antibody reactions.

We have found that two surfactants generally used in our laboratory, 'Tween 80' (polyoxyethylene sorbitan mono-oleate) and 'Gantrez AN-119' (a copolymer of methyl vinyl ether and maleic anhydride), inactivate antibody when added at concentrations used for immunological studies.

Three rabbits were immunized with crystalline bovine serum albumin (BSA). The concentration of antibody in each rabbit serum was determined by the quantitative precipitin test, as described by Kabat<sup>3</sup>. All protein concentrations were determined by the method of Lowry<sup>4</sup>.

Each rabbit serum was tested for inactivating effects of the two surfactants. All rabbit sera were diluted 1:4 with 0.01 molar borate buffered saline, pH 8.2. To 0.5 ml. of the diluted rabbit sera, 1.0 ml. of either 'Tween 80' or 'Gantrez AN-119' was added in decreasing concentrations. The surfactants were previously prepared in the same buffer as the antisera. The mixtures of surfactant and antisera were incubated for 30 min at 37° C before addition of 0.5 ml. of BSA containing sufficient antigen to bring the reactants to the equivalence point. The tubes were then incubated for

another hour at 37° C and placed at 4° C for an additional 48 h. The precipitates were washed and the total protein was determined. The loss of precipitable protein as compared with controls was taken as the degree of inactivation.

Results are shown in Fig. 1. The inactivation caused by the presence of 'Tween 80' seems to increase to a maximum. This may be caused either by inactivation of a particular antibody fraction or by binding of surfact-

Fig. 1. Antibody inactivation in the presence of surfactants as determined by antigen-antibody precipitation at equivalence for each rabbit.

ant to antigen, which blocks specific antigenic sites. The results obtained with the 'Gantrez AN-119' seem to be completely dependent on concentration and may represent denaturation, antibody dissociation or even soluble antigen-antibody complex formation. No antibody activity could be detected in the supernatants from any of these experiments.

A series of experiments was carried out to determine whether the loss of precipitable protein was caused by (a) antibody dissociation; (b) formation of soluble antigen-antibody complexes; or (c) irreversible denaturation. Antigen adsorbed to bentonite was prepared by modification of the method of Bozicevich<sup>5,6</sup>. Each serum was titred by the antiserum dilution method. Titres were repeated after addition of 'Tween 80' or 'Gantrez AN-119' to the antiserum. If the loss of precipitable antibody, as observed in Fig. 1, were caused by the formation of a soluble complex, the bentonite titre would not be expected to decrease because the antigen is bound to an insoluble matrix and cannot solubilize. Decreased titres were observed (Table 1).

Table 1. BENTONITE FLOCCULATION TITRE VERSUS SURFACTANT CONCENTRATION

Serum No.	Total antibody (mg/ml.)	Original reciprocal titre	Surfactant	Reciprocal titre after addition of surfactant. Concentration of surfactant (per cent)		
				5.0	0.5	0.01
218	1.85	256	'Tween 80'	128	128	256
			'Gantrez AN-119'	64	256	256
219	1.21	128	'Tween 80'	64	64	128
			'Gantrez AN-119'	32	64	128
220	1.40	256	'Tween 80'	128	128	256
			'Gantrez AN-119'	32	64	256

The possibility that the surfactants were causing reversible antigen-antibody dissociation was also considered. Three rabbit sera were pooled and fractionated by precipitation of the globulins with one-third saturated ammonium sulphate. The globulins were adsorbed to bentonite as previously described<sup>5,6</sup>. The sensitized bentonite was titred against BSA before and after addition of either 'Tween 80' or 'Gantrez AN-119'. Loss of titre was observed on the addition of either surfactant. The sensitized bentonite was centrifuged and washed free of the surfactants, resuspended, and retitred. No recovery of antibody activity was observed. Either the surfactants irreversibly inactivated the antibody bound to bentonite or remained adsorbed to the bentonite in some manner, causing continued inhibition. Washing and resuspending sensitized bentonite in the absence of surfactants did not affect the titre.

These experiments strongly indicate the necessity of carefully considering the possible effects a surfactant may have when added to biological systems. It cannot be assumed that a surfactant, if used in low concentrations, will have little or no adverse effects on the system being investigated.

## Detection of Antibodies against Mitochondria by the Fluorescent Antibody Technique with Smears of Rat Liver Cells

SERA of patients with primary biliary cirrhosis contain autoantibodies against a non-organ specific cytoplasmic component, which are probably mitochondria<sup>1,2</sup>. A convenient way to detect these antibodies is by the fluorescent antibody technique using unfixed cryostat sections of human or rat organs. Sections of renal cortex proved to be the most suitable for the demonstration of cytoplasmic

Fig. 1. Indirect fluorescent antibody technique on smears of a rat liver cell suspension with fluorescein conjugated anti-human-complement. (A) Incubated with serum of a patient with primary biliary cirrhosis showing staining of mitochondria; B, incubated with serum containing ANF, showing speckled staining of nuclei of a bi-nuclear liver cell; (C) control with normal serum, no staining.

antibodies. Liver sections showed the same coarsely granular staining, but because of the uniform appearance of this tissue, it was difficult to distinguish the fluorescence obtained with the weaker sera from non-specific artefacts<sup>1</sup>.

This technique is suitable for the detection of these antibodies, but a cryostat is essential. We have tried to show that smears of rat liver cell suspensions can be used to detect antibodies against mitochondria as well as antibodies against nuclei.

Rat liver cell suspensions were prepared as follows: rats were decapitated and 0.04 molar sodium citrate-0.15 molar sucrose (adjusted to pH 7 with citric acid) was perfused through the aorta for 3 min. The liver tissue was minced with scissors and suspended in a hand-driven 'Teflon' pestle in 0.25 molar sucrose at 0°-4° C. After filtration through nylon gauze the suspension was washed twice with 0.25 molar sucrose, after which it consisted of a pure suspension of single cells<sup>2</sup>. Smears were prepared on thoroughly cleaned slides and air dried. If they were not used immediately, they were stored, sometimes for several weeks, at -20° C. The indirect fluorescent antibody technique was used with a fluorescein conjugated rabbit anti-human-complement serum (anti- $\beta_{1A}$ -C and - $\beta_{1E}$ , supplied by the Central Laboratory of the Netherlands Red Cross Blood Transfusion Service) or with various anti-human gamma globulin conjugates. Usually the conjugates were applied in 1:5-1:10 dilutions in buffered saline. Inactivated (30 min, 56° C) sera were incubated for 30 min at room temperature. Thereafter the smears were incubated with fresh human AB serum for 30 min at room temperature, when the anti-complement conjugate was to be used. To avoid aspecific staining of an irregular, stringy appearance in the periphery of the cytoplasm, the fresh AB serum, as well as the conjugate, was absorbed with lyophilized rat liver homogenate (respectively 50 and 100 mg/ml.).

Sera from patients with primary biliary cirrhosis and serum from a patient with breast cancer who may have had immunological tumour resistance<sup>4</sup> showed coarse granular staining in the cytoplasm of the liver cells. The fluorescent granules were seen best when the  $\times 40$  objective was focused on a level just above the nucleus. Sera known to contain anti-nuclear factor (ANF) stained the nuclei. Normal sera stained neither granular cytoplasmic components nor nuclei.

The anti-gamma globulin conjugates showed smooth aspecific staining when the undiluted sera were used. Staining with anti-complement conjugate was much more distinct because there was no background fluorescence (Fig. 1). The results were as good as those from unfixed rat renal cryostat sections. When the smears were compared with renal sections the sera of three patients with mitochondrial antibodies and one with ANF showed no difference in titre, and the staining of the smears was much more clear cut than the staining of the sections. Smears stored for up to 6 weeks showed no diminution of antigenicity, because the pattern and intensity of staining and also the titre of the three anti-mitochondrial sera were the same as those of fresh smears. Fluorescent staining of nuclei with ANF sera was nearly as strong with the stored smears as with fresh ones. As Walker *et al.* found, fluorescent staining of the granules was only positive when the smears were air-dried. Staining was abolished by fixation with ethanol or methanol and decreased by fixation with acetone.

Sera of patients with primary biliary cirrhosis are supposed to contain antibodies to mitochondria, and so it seemed logical to assume that the fluorescent granules represent liver mitochondria. Electron microscopy has shown that isolated rat liver mitochondria incubated for 30 min with one of these sera, and negatively stained by PTA, had a fringe on the outer membrane (Fig. 2). The size and shape of this fringe are typical of antibody deposition<sup>5,6</sup>. The fringe was absent on the fragments of endoplasmic reticulum and plasma membranes which were

Fig. 2. Electron micrograph of isolated rat liver mitochondrion negatively stained with 1 per cent PTA pH 7, after incubation for 30 min with antiserum. On the outer surface of the mitochondrion a fringe representing antibody deposition is visible. ( $\times 192,700$ .)

occasionally present as contaminants in the same preparation. Control mitochondria incubated with normal human serum did not show fringes.

It can be concluded that smears of rat liver cell suspensions are a suitable substrate for the detection in human sera of antibodies to mitochondria as well as to nuclei. The method is particularly useful for routine purposes in laboratories where cryostats are not available. For the detection of mitochondrial antibodies the results are more clear cut with anti-human complement conjugate than with anti-human gamma-globulin conjugate.

We thank Dr E. L. Benedetti for carrying out the electron microscope work.

### Time-dependent Immunosuppressive Effects of Anti-thymocyte Serum

THE effectiveness of immunosuppressive agents depends greatly on the time of their administration in relation to the time of immunization. The immunosuppressive effects of heterologous anti-lymphoid sera are under intensive investigation but little seems to be known about their time-dependence. Monaco *et al.*<sup>1</sup> found that a course of seven daily injections was most effective in prolonging the survival of allogeneic skin grafts if it was given during the week before grafting and was progressively less effective the later it was begun. On the other hand, Levey and Medawar<sup>2</sup> found that a course of two injections was marginally more effective if given on days +2 and +5 relative to the time of grafting than if given on days -1 and +2.

It was therefore of interest to study the effect on the antibody response of anti-thymocyte serum given at different times before or after a single injection of antigen.

Anti-thymocyte serum was produced by the method of Levey and Medawar<sup>2</sup> by injecting rabbits intravenously

Fig. 1. Effect of a single dose of anti-thymocyte serum on the number of antibody-containing cells in the spleen 4 days after injecting sheep red cells. Curves drawn through geometric means of the values in each group. C, Counts in mice given sheep red cells only; p, probabilities that the differences between the groups indicated were due to chance.

Fig. 2. Effect on number of antibody-containing cells in the spleen of anti-thymocyte serum given on day -2 or day +2 relative to an injection of sheep red cells. C, Mice given sheep red cells only.

with two lots of  $10^6$  CBA mouse thymus cells at an interval of two weeks and bleeding a week after the second injection. Sera were heated at  $56^\circ\text{C}$  for 30 min and stored at  $-20^\circ\text{C}$ .

Male CBA mice, weighing 20–25 g, were injected intraperitoneally with 0.2 ml. 10 per cent (v/v) formalized sheep red cells in saline. Groups of between six and twelve mice were given single injections of anti-thymocyte serum, 0.25 ml./10 g body weight subcutaneously, at various times before or after the injection of red cells. Control mice were given red cells only. The spleens were removed 4 days after the antigen injection and the numbers of cells containing haemolysin or haemagglutinin in the spleens were counted by Jerne's method<sup>3</sup> and a modification of

Zaalberg's method<sup>4</sup>. The results are shown in Fig. 1. The values were compared statistically by a distribution-free ranking method of Wilcoxon<sup>5</sup>.

There was a significant depression in the response ( $P < 0.01$ ) if anti-thymocyte serum was given at any time between days -6 and 0, with a maximum effect on day -3. The haemolysin-cell response was not significantly depressed if the injection of antiserum was delayed to day +1 or later. The agglutinin-cell response was depressed even with late administration, but the depression was minor (to about half the control values).

In a second experiment, mice were given sheep red cells on day 0 and 0.25 ml. anti-thymocyte serum/10 g body weight on day -2 or +2. Counts of cells containing antibody were made from day +2 to +6. Administration on day -2 markedly reduced the response, whereas administration on day +2 had no effect (Fig. 2).

In a third experiment, mice were injected once with sheep red cells and then daily with 0.2 ml. of anti-thymocyte serum or normal rabbit serum/10 g body weight, subcutaneously, from day +2 to +6 inclusive. Spleens were examined on days +7 and +11. The results are shown in Table 1. Depression of haemolysin-cell counts by anti-thymocyte serum was relatively minor (to one-third or one-half of the control values) and the level of cells containing agglutinin was not materially affected.

It therefore seems that the processes leading to production of humoral antibody are sensitive to anti-thymocyte serum if it is given before, or simultaneously with, the antigen, but lose sensitivity to this agent within 24 h of administration of antigen. This sort of timing effect could be caused by a delayed absorption of the agent, but this is not likely in view of the failure of a relatively prolonged course of injections to cause more than a modest depression of the response (experiment 3) and the finding by Brent, Courtenay and Gowland<sup>6</sup> that lymphoid cells taken from mice 24 h after administration of anti-thymocyte serum had a reduced ability to cause a graft-versus-host reaction. It is therefore unlikely that heterologous anti-lymphoid sera act during the stage of cell proliferation induced by antigen. The fact that the greatest effect is produced by giving anti-thymocyte serum 3 days before the antigen makes it difficult to believe that the serum acts directly on the cells which are sensitive to antigen. The serum can scarcely take 3 days longer than the antigen to reach these cells, nor does it seem likely that, once having reached them, it would take 3 days to damage or inactivate them.

## BIOCHEMISTRY

## Photoreactions of Retinol and Derivatives sensitized by Flavins

CRYSTALLINE riboflavin is present in the eyes of several fishes and mammals (for example, *Galago crassicaudatus*)<sup>1</sup>. Its role in vision, however, is obscure. One possible function may be that of a transducer to convert blue light (efficiently absorbed by the flavin but not by rhodopsin) into energy that can be utilized by rhodopsin producing the chemical signal. This conversion may be achieved by the trivial process of re-emission (the wavelength of fluorescence of riboflavin is at 530 m $\mu$ , which is favourable for absorption by rhodopsin)<sup>2</sup> or by direct energy transfer either of a singlet-singlet or of a triplet-triplet type.

In our studies we have chosen all-*trans*-retinol and the 13-*cis*-derivative as models for the photosensitive part of the visual pigment rhodopsin. This choice was primarily governed by the consideration that the absorption spectra of these compounds involve transitions of higher energy than the longest wavelength absorption of riboflavin. This, then, excludes the possibility of the trivial process or of singlet-singlet energy transfer in our system.

When an anaerobic solution of all-*trans*-retinol ( $1.6 \times 10^{-5}$  molar) and lumiflavin ( $2 \times 10^{-5}$  molar) in 98 per cent methanol/water is illuminated (using light composed of wavelengths above 400 m $\mu$ ) a gradual decrease in the peak height of retinol at 328 m $\mu$  is observed (Fig. 1). No reaction is found for either of the reactants alone under these conditions. Lumiflavin can be replaced by riboflavin or flavin mononucleotide (FMN) and all-*trans*-retinol by 13-*cis*-retinol. In the dark no interaction is observed between retinol and lumiflavin either by spectrophotometry or by fluorescence methods.

The photoreaction is inhibited by  $10^{-2}$  molar nickel sulphate, oxygen and potassium iodide (Fig. 1). Potassium iodide also quenches the fluorescence of lumiflavin but less efficiently than it quenches the photoreaction (Fig. 2).

Thin-layer chromatography of the reaction mixtures of 13-*cis*-retinol and lumiflavin has shown qualitatively the formation of all-*trans*-retinol. The reverse of this reaction was also observed although in this case the analytical procedure did not distinguish the 13-*cis*- from the 11-*cis*-isomer. The thin-layer chromatography was essentially as already described<sup>3</sup>.

Thus the flavins can sensitize a reaction of retinol similar to that observed in the ultra-violet illumination of retinol or retinal alone<sup>4</sup>. The *cis-trans* isomerization is undoubtedly accompanied by some destruction of the compound. We have no direct evidence for the mechanism

Fig. 1. Sensitized photoreaction of all-*trans*-retinol. ●, Retinol and lumiflavin; ■, retinol, lumiflavin and  $10^{-2}$  molar nickel sulphate; ○, retinol, lumiflavin and oxygen.

Fig. 2. Inhibition of sensitized photoreaction against fluorescence quenching by potassium iodide (concentrations shown in brackets).

of the photosensitization, but the quenching experiments suggest that the flavin triplet is involved as in other photoreactions of flavins<sup>5</sup>. Triplet-triplet energy transfer has been suggested for the lumichrome-sensitized isomerization of stilbene-4-carboxylic acid<sup>6</sup> and the process described here may involve a similar mechanism. Alternatively the triplet may react directly with retinol to form a covalent labile intermediate similar to that formed in the reaction of phenylacetic acid with 3-methyl-lumiflavin<sup>7</sup>.

### Localization of Lactic Dehydrogenase Isozymes in Lysosomal Fraction of the Neutrophil of Normal Human Blood

THE lysosomal fraction of the leucocyte is the principal source of peroxidase and hydrolases<sup>1</sup>, and our unpublished results show that it also contains lactic dehydrogenase (LDH) usually found in the soluble compartment of cells. Vesell and Bearn<sup>2</sup> and Vesell and Osterland *et al.*<sup>3</sup> have shown that whole homogenates and sonicates of the leucocyte contain four isozymes of lactic dehydrogenase.

In this communication we shall show that the isozymes of lactic dehydrogenase of the human white cell are bound to the particulate of the lysosomal fraction, and that this accounts for all the isozymes of the white cell.

The preparation of lysosomes of the human leucocytes<sup>1</sup> has been modified by use of a Ficoll gradient. LDH activity was quantitatively analysed spectrophotometrically<sup>4</sup>; however, a Process and Instrument spectrophotometer was used to follow the reaction of the 3400 Å with an expanded scale, wherein 0.10 absorbance is spread over a 12 in. scale. The enzymes were examined on acrylamide gels, using the 470 apparatus manufactured by the E.C. Company of Swarthmore, Pennsylvania. Instead of using the gel preparation described by that company, the stacking gel technique, used on disc electrophoresis<sup>5</sup>, was applied with slight modification in composition and preparation of the gels as follows (the letters in parentheses refer to stock solutions tabulated in ref. 6).

**Lower gel:** One part of (A) which contained 48 ml. 1 normal hydrochloric acid, and 36.3 g *tris* made up to 100 ml. with distilled water, and 2 parts of (C) which contained 30 g of acrylamide monomer and 0.8 g of *bis* (*N,N*-methylene bis acrylamide monomer) made up to 100 ml. with distilled water, and 1 part of distilled water which was added just before mixing lower gel A and B, and 0.1 ml. of TEMED (*N,N,N,N*-tetramethylethylenediamine). Lower gel B consisted of 0.2 g of ammonium persulphate in 100 ml. of distilled water. Equal parts of lower gel A and lower gel B were mixed and poured into the apparatus without air bubbles. The level of the gel was adjusted immediately and it was allowed to set for 20–30 min for polymerization. After polymerization, the upper gel was added.

**Upper gel:** One part of (B) (25.6 ml. 1 molar orthophosphoric acid and 5.7 g *tris*, made up to 100 ml. with distilled water), 2 parts of (D) (10 g of acrylamide and 2.5 g of *bis* made up to 100 ml. with distilled water); 1 part of (E) (4.0 mg of riboflavin in 100 ml. of water), and 4 parts of distilled water. The upper gel was polymerized after putting the teeth in place and exposing the gel to fluorescent light for 20–40 min. After polymerization, the teeth were removed and the apparatus carefully transferred to the cold room where known amounts of the samples were applied into each slot. The buffer used in this experiment was *tris*-glycine buffer (*tris*, 6 g; glycine, 28.8 g; made up

Fig. 1. Enzyme studies representing the results obtained when 4,000 g fraction is separated on a Ficoll gradient and the gradient is sliced into eleven sections from the bottom to the top; 0 representing the bottom slice and 11 representing the top. To avoid confusion, the results are plotted on two separate charts although they are done on the same run. In a, ■ indicates lysozyme; ▲, peroxidase; ●,  $\beta$ -glucuronidase; ○, LDH; ×, protein; □, acid phosphatase; △, amino-peptidase. In b, ■ indicates protein; ▲, catalase; ●, succinate cytochrome-c reductase; ○, DPNH cytochrome-c reductase; ×, cytochrome oxidase.

Fig. 2. Acrylamide gel electrophoresis of the lysosomal fraction (Lys), human white blood cell (WBC) showing the presence of LDH isozymes. RBC-1 (1,034  $\mu$ g protein) and RBC-2 (517  $\mu$ g protein) are haemolysed human red blood cells. WBC-1 (193  $\mu$ g protein) and Lys-2 (13  $\mu$ g protein) are sonicated samples of leucocytes and lysosomes (tube 2) in Fig. 1a. WBC-2 (1,161  $\mu$ g protein) represents 6 times as that of WBC-1. In order to increase the amount of material, fraction 2 was concentrated by lyophilizing and resuspending before application. Thus Lys-2 (1,975  $\mu$ g protein) and Lys-3 (1,234  $\mu$ g protein) represent concentrated lyophilized samples; WBC-3 (784  $\mu$ g protein) was treated in a similar fashion. The stained spot near the original over WBC-3 is an insoluble aggregate.

to 1 l., pH 9.0). Electrophoresis was carried out for 7 h at 50 V and 40 m.amp. The gel was transferred to a tray and was incubated with a developing reagent, as described by Vesell<sup>6</sup>, in the dark at room temperature.

From Fig. 1a, it can be seen that most of the LDH of the 4,000 g pellet is found in tubes 1, 2 and 3 respectively, representing 66 per cent of the original enzyme activity of the pellet. Although LDH activity was also found in tubes 8 and 9 (the mitochondrial fraction), one half of the rate of disappearance of DPNH took place in the absence of pyruvate. On this basis, only 11 per cent of true LDH activity can be assigned to this fraction. No LDH activity was observed in tubes 1, 2 and 3, when pyruvate was left out of the test solution. Of the total white cell LDH activity, 43–45 per cent can be accounted for in the lysosomal fractions.

The fact that the LDH isozymes of the whole cell are located principally in the lysosome is indicated in Fig. 2, where whole cell sonicates, red blood cell haemolysates and lysosomal preparations are compared. While the fast-moving A and B isozymes are seen in all fractions, increasing the concentration by lyophilization and resuspension, a third band is observed in the white cells and the lysosomes. Only in the case of lyophilized white cells is a slow-moving fourth band seen; this was seen when increased quantities of the white cell homogenates were applied without lyophilization (WBC-2). Although RBC-1 represents twice the amount of RBC-2, no slow-moving component was observed. As observed by Vesell<sup>7</sup>, experiments by frozen and thawed material showed the slow-moving isozyme. For this reason, sonication was chosen.

The 4,000 g pellet which was the starting material on the Ficoll gradient is described in a previous report<sup>1</sup>. It contains the peroxidase and hydrolytic enzymes and a small amount of mitochondria found in tube 9, similar to that seen on the sucrose gradient reported previously.

Detailed studies of other enzymes along with electron micrographs of the particulates separated in tube 2 are shown in Figs. 1b, 3a and 3b. These data provide the necessary evidence that these particulates are the lysosomal fraction of the white cell. The specific granules and the large multivesicular bodies seen in the electron micrographs are morphologically similar to what is now recognized in lysosomal fractions as described by Novikoff<sup>8</sup>, who suggested that a variety

a

b

Fig. 3. Electron micrographs of material from tube 2 (Fig. 1a). a,  $\times 25,200$ ; b,  $\times c. 76,000$ .

of lysosomes may be produced in the form of coated vesicles, dense bodies, multivesicular bodies, and autophagic vacuoles containing endoplasmic reticulum and ribosomes. These figures can all be seen in Figs. 3a and b, which are probably the purest lysosomal fraction yet obtained from a normal human leucocyte. In more than thirty-five preparations made in this laboratory, the hydrolases characteristic of this fraction are always accompanied by myeloperoxidase.

Although the LDH activity is apparently associated with the particulate containing the peroxidase and hydrolytic enzymes<sup>1</sup>, it cannot be said that the enzyme is within the cell, but rather attached to the membrane. This reasoning is based on the observation that there is no increase in the LDH activity of the particulate of the lysosomal fraction following sonication or destruction of the intact particle. In the case of peroxidase and hydrolytic enzymes, the activity is increased markedly under these conditions. The statement may be made that although LDH is recognized as a soluble enzyme, in the white cell it has a strong affinity for the lysosomal membrane. In regard to the presence of the LDH in the mitochondrial fraction, one may conjecture that light lysosomes may be present as indicated by the enzyme markers found there as indicated here by peroxidase<sup>1</sup>; the finding, however, that one half of the activity is retained in the absence of pyruvate does indicate that a DPNH oxidase could be present in sufficient quantities along with the electron transport system to overcome the amount of cyanide used in the test solution. This was not investigated further. Finally, the specific activity of LDH of the whole cell homogenate was 9.1 units/mg protein, while that of the particulate in tube 2 of Fig. 1a was 311 units/mg protein, a concentration of about 34-fold.

This work was supported in part by grants from the National Institutes of Health, US Public Health Service. We thank the Merck Sharp and Dohme Company for

making available the supply of white cells used in these experiments.

### Possible Duplication of Haemoglobin $\alpha$ -Chain Locus in the Iru Macaque

THE iru macaque (*Macaca irus*) is polymorphic for a minor haemoglobin component which resembles human Hb-A<sub>2</sub> in electrophoretic mobility and concentration but differs from it in having a common  $\beta$ -chain with the normal major component, Hb-A<sub>1</sub> (ref. 1). Two major haemoglobin variants Hb-P<sub>mi</sub> and Hb-Q<sub>mi</sub> are also frequent in this species and these also differ from Hb-A<sub>1</sub> in their  $\alpha$ -chains. Some animals carry three haemoglobins, for example Hb-P<sub>mi</sub> ( $\alpha_{Pmi}\beta_{A1}$ ), Hb-A<sub>1</sub> ( $\alpha_{A1}\beta_{A1}$ ) and the minor component ( $\alpha_{Xmi}\beta_{A1}$ ), and therefore have three types of  $\alpha$ -chain ( $\alpha_{A1}$ ,  $\alpha_{Pmi}$  and  $\alpha_{Xmi}$ ). Hb-P<sub>mi</sub> and Hb-A<sub>1</sub> are probably determined by allelic genes.

It was therefore suggested<sup>1</sup> that the minor component arose by duplication of the  $\alpha$ -locus in a manner analogous to the proposed origin of Hb-A<sub>2</sub> by a  $\beta$ -locus duplication<sup>2</sup>.

In several animal species a number of different haemoglobin chains are produced during the individual life cycle, for example the  $\delta$ ,  $\beta$ ,  $\gamma$  and  $\epsilon$ -chains in man. These are usually non- $\alpha$  chains which are thought to have originated by gene duplication. On the other hand, in a few cases<sup>3-5</sup> in which individuals of a species carry more than one type of  $\alpha$ -chain it has been argued that this is a result of misreading of a codon during  $\alpha$ -chain synthesis rather than duplication of the locus. In this communication more detailed structural studies of the minor component of *M. irus* are reported. These studies confirm that the minor component differs from the normal major component in the  $\alpha$ -chain and strengthen the view that gene duplication rather than misreading of the genetic code provides the better explanation of the situation.

The minor haemoglobin component (about 4 per cent of total haemoglobin) and Hb-A<sup>mi</sup> were isolated by chromatography on 'Sephadex CM'<sup>6</sup>, followed by chromatography on 'Sephadex DE'<sup>7</sup>, from an animal carrying only these two haemoglobins.

Fig. 1. Top: Fingerprint of *M. irus* haemoglobin Hb-A<sup>mi</sup>. Bottom: Fingerprint of *M. irus* minor haemoglobin component.

Globins, prepared from the purified haemoglobins by precipitation in acid acetone at  $-20^{\circ}\text{C}$ , were digested with trypsin and fingerprinted by paper electrophoresis in pyridine, acetate and water (10:0.4:90) buffer pH 6.4, followed by chromatography in pyridine, isoamyl alcohol, water (35:35:27)<sup>8</sup>. The peptides were stained with 0.2 per cent ninhydrin. The presence of tryptophan was detected with Ehrlich's reagent, histidine with Pauly's reagent, arginine with Sakaguchi's reagent and tyrosine with the nitrosonaphthol reagent<sup>9</sup>.

Several differences between the fingerprints of the minor component and Hb-A<sup>mi</sup> were visible. These are shown in Fig. 1 and are listed below with the same numbering. Two separate samples from the same animal

gave identical results. (1) No peptide was visible in the  $\alpha$  T3 position of the minor component fingerprint; in addition, no tryptophan stain was visible in this position, in contrast to  $\alpha$  T3 of Hb-A<sup>mi</sup>, which is tryptophan positive. (The peptide numbering used in this paper is by analogy with human Hb-A as discussed in ref. 1.) (2) The presence of a new positively charged peptide was noted in the minor component fingerprint; this did not stain for arginine, histidine, tyrosine or tryptophan. (3) An extra peptide, only weakly stained by ninhydrin, was visible; this peptide was positive for arginine. (4) The peptide pattern in this region was clearly different from that found in Hb-A<sup>mi</sup>; instead of a diffuse double spot, a compact single spot was present. (5)  $\alpha$  T1 + 2 was absent in the minor component fingerprint. (6 and 7)  $\alpha$  T8 + 9 ox. and T9 ox. both had a lower chromatographic mobility than the corresponding peptides found in Hb-A<sup>mi</sup>; both peptides were histidine positive. The difference in  $\alpha$  T9 can only be seen with this stain. (8)  $\alpha$  T4 was more negatively charged in the minor component than in the Hb-A<sup>mi</sup> fingerprint. It was identified by being positive for arginine, histidine and tyrosine in both fingerprints. The difference in mobility was confirmed by one dimensional electrophoresis of the tryptic digests of the minor component and Hb-A<sup>mi</sup> in parallel, and subsequent staining for histidine. (9) An extra peptide was visible in the neutral region and was positive for arginine.

Comparison of the  $\beta$ -chain peptides of each fingerprint after staining with ninhydrin, as well as for arginine, histidine, tryptophan and tyrosine, revealed no differences.

These results confirm the previous finding that the  $\beta$ -chains of Hb-A<sup>mi</sup> and the minor component are identical and that they differ in their  $\alpha$ -chains. The peptides  $\alpha$  T1 + 2,  $\alpha$  T3,  $\alpha$  T4 and  $\alpha$  T9 of the latter differ from those of Hb-A<sup>mi</sup>, and so it appears that there are at least four amino-acid differences between these haemoglobins, an overall divergence of the same order as that found between Hb-A and Hb-A<sub>2</sub> using the same technique.

Misreading of the genetic code is a plausible explanation of the occurrence of more than one type of  $\alpha$ -chain in the horse<sup>3</sup>, mouse<sup>4</sup> and rabbit<sup>5</sup>, but the situation in *M. irus* is not readily explained by this hypothesis. Fingerprint evidence indicates that the minor component differs from the normal haemoglobin in more than one substitution. If gene duplication is discarded as an explanation we must suppose that this species is polymorphic for a gene with several mutant codons susceptible to misreading. It is not yet clear whether the charge difference of the minor component can be accounted for by a single substitution. If, however, more than one substitution is involved and any of them are caused by translational errors, more than one minor haemoglobin band should regularly be produced, which is not the case. Our earlier work<sup>1</sup> suggested that the minor component occurs at random among major haemoglobin phenotypes. If, then, a misreading producing a change of charge occurred in the synthesis of the variants Hb-P<sup>mi</sup> or Hb-Q<sup>mi</sup>, which themselves differ in charge from Hb-A<sup>mi</sup>, two minor components should sometimes be seen in the phenotypes A<sup>mi</sup>P<sup>mi</sup> or A<sup>mi</sup>Q<sup>mi</sup>, but this has not so far been observed.

The minor components of Old World monkeys and anthropoid apes present some interesting evolutionary problems. A minor component occurs in chimpanzees, gorillas and orangs and we have observed (unpublished work) two electrophoretically distinct minor components, present either alone or together in a sample of nine gibbons (*Hylobates lar*). Pongids are usually assumed to have a homologue of the human  $\delta$ -chain and it has been shown<sup>10</sup> that, in the orang, the minor components have an  $\alpha$ -chain like that of major components. If this assumption is correct the  $\delta$ -chain presumably arose by the postulated  $\beta$ -locus duplication before separation of pongid and hominid lineages  $3-4 \times 10^7$  yr ago and the human  $\delta$ - and  $\beta$ -chains have since diverged by ten substitutions. In the case of macaques, however, a minor compo-

ment was not found in *Macaca nemestrina*<sup>11</sup>, *M. speciosa*, *M. sinica*, *M. mulatta* or *M. cyclopis* (unpublished work), nor in three species of the related baboons (*Papio*)<sup>12</sup>. On the present incomplete evidence it seems that either a minor component may have been present in some ancestral macaque but has been lost except in *M. irus* or that it arose after this form became specifically distinct, if indeed it is<sup>13</sup>. In either case a time span considerably less than  $3-4 \times 10^7$  yr is likely to be involved and yet at least four substitutional differences from the *M. irus*  $\alpha$ -chain have evidently accumulated.

### Synthesis of ATP driven by a Potassium Gradient in Mitochondria

THE possibility of reversing energy-dependent ion transport to synthesize ATP<sup>1,2</sup> has apparently been realized in the case of chloroplasts subjected to acid-base transitions<sup>3</sup>. In no other case has net ATP synthesis coupled to ion transport been reported although incorporation of phosphorus-32 into ATP has been shown to be enhanced in erythrocytes by adjusting the sodium and potassium gradients so as to "reverse the Na<sup>+</sup>-pump"<sup>4</sup> and during step-changes in pH applied to mitochondria<sup>5</sup>. The high apparent efficiency of the accumulation of potassium supported by ATP in mitochondria treated with the antibiotic valinomycin<sup>6</sup> suggested that, provided the kinetic barrier was not inordinately large, ATP synthesis should be demonstrable in the absence of respiration if the direction of net potassium movement were reversed (that is, during potassium efflux).

Net synthesis of ATP accompanying stimulation of potassium efflux by valinomycin is shown in Fig. 1A. The increase in ATP is accompanied by an equivalent decrease in ADP and a negligible change in AMP. There is thus a net increase in high energy phosphate indicating that the elevation in ATP is not mediated by adenylate kinase. The presence of the rotenone block prevents synthesis of ATP by means of energy derived from the oxidation of endogenous substrate. Oxygen consumption and fluorescence (as a measure of the pyridine nucleotide redox state), [K<sup>+</sup>] and [H<sup>+</sup>] were recorded simultaneously by means of the appropriate electrodes and apparatus previously described<sup>7</sup>. The observed inhibition of respiration by rotenone substantiated the essentially complete block of electron transfer. If 10 mmolar potassium is added to the medium, instead of potassium efflux and elevation of ATP, a very slight net accumulation of potassium and

decrease in ATP occur on addition of valinomycin (Fig. 1A), which may be attributed to the resultant decrease of the transmembrane potassium gradient. Replacement of the exogenous potassium with 10 mmolar sodium actually slightly enhanced the rise in ATP during potassium efflux compared with the basic system which was free of alkali ions. Reagents which interfere with the communication between ion transport and ATP—oligomycin and 2,4-dinitrophenol—prevent the increase in ATP when valinomycin is added as shown in Fig. 1B. If valinomycin is replaced by nigericin<sup>8</sup>, which catalyses an even more active potassium efflux under these conditions, no concomitant effect on the endogenous level of ATP is observed. The corresponding changes in [K<sup>+</sup>] and [H<sup>+</sup>] of the suspending medium as detected by the appropriate glass electrodes are shown in Figs. 2A and B, respectively.

The rapid initial discharge of potassium when valinomycin is added is followed by a slower, sustained leakage of potassium. Oligomycin decreases the rapid initial discharge of potassium while, if anything, 2,4-dinitrophenol stimulates the initial potassium efflux. This pattern—diminution by an energy transfer inhibitor and enhancement by an energy dissipating agent—is consistent with the initial, rapid component of potassium efflux being energy-linked. The rapid potassium flux, moreover, exhibits the same time course as the rise in ATP. In contrast, the rapid and extensive potassium efflux and hydrogen ion accumulation initiated by nigericin does not appear to be energy-linked: no associated rise in ATP is observed, nor are these ion movements affected by oligomycin. This is consistent with work to be published in detail elsewhere which indicates that nigericin bypasses the energy-linked mechanism, presumably by serving as a negatively charged cation carrier catalysing passive potassium ion for hydrogen ion exchange. It is clear from these results that potassium efflux or hydrogen ion accumulation *per se* is not necessarily linked to the formation of ATP.

These observations support the conclusion that valinomycin increases access of potassium to an energy-linked cation transport system tightly coupled to ATP synthesis.

Fig. 1. A, To medium containing 300 mmolar sucrose and 5 mmolar *tris*-phosphate (pH 6.5) at 20° C, rat liver mitochondria equivalent to 6 mg protein/ml. were added followed by rotenone (0.2  $\mu$ g/mg protein) after 1 min. Valinomycin (0.03  $\mu$ g/mg) was added at 6 min either in the absence of added potassium (—) or when the basic medium was supplemented with 10 mmolar potassium chloride (---). Samples were fixed with perchloric acid and analysed for adenine nucleotides enzymatically<sup>10</sup>. Experimental values for ATP, ADP and AMP are represented by  $\Delta$ ,  $\bullet$  and  $\blacksquare$ , respectively. B, Except where noted the conditions were identical to those of A. The curves represent: valinomycin (0.036  $\mu$ g/mg) added at 4 min (—); nigericin (0.07  $\mu$ g/mg) added at 4 min in place of valinomycin (---); control in which neither was added (.....). The complete block of elevation in ATP on addition of valinomycin, 1  $\mu$ g/mg, or 60  $\mu$ molar 2,4-dinitrophenol is also shown ( $\square$ , curves labelled accordingly).

Fig. 2. A, Net efflux of potassium (indicated by an increase in  $[K^+]$  of the medium), and B, the decrease in  $[H^+]$  stimulated by addition of valinomycin (vertical arrows) and the effect of prior addition of either dinitrophenol or oligomycin is shown. The dashed traces are those in which nigericin was added instead of valinomycin; all traces correspond to the experiments of Fig. 1B.

The stoichiometry under optimum conditions for the energy requiring accumulation process has been reported previously as 6.5  $K^+$ /ATP hydrolysed<sup>6</sup>. The stoichiometry between potassium efflux and ATP synthesis under the conditions used here is roughly 10  $K^+$ /ATP formed. The net potassium efflux observed during the formation of ATP is in the range of 20  $\mu$ moles/g protein, while the apparent hydrogen ion accumulation is a variable fraction of this. Under these conditions, the potassium gradient is at least 100 (that is, internal  $[K^+]$  at least 40 mmolar, extra-mitochondrial  $[K^+]$  approximately 0.4 mmolar). Because the membrane pH gradient is in all probability only a fraction of a pH unit even in actively respiring mitochondria<sup>9</sup>, it is unlikely that the movement of hydrogen ion down a pH gradient could supply the energy necessary for driving ATP synthesis rather than the movement of potassium down its concentration gradient.

These results indicate that intact mitochondria possess a highly efficient cation transport system tightly "coupled" to phosphorylation. Under conditions in which gradients highly unfavourable for energy-driven ion translocation are imposed experimentally, reversal of cation transport may drive ATP synthesis in a manner similar to that reported to operate in erythrocytes<sup>4</sup>.

## Partial Purification of a DNA-polymerase from the Non-histone Chromatin Proteins of Rat Liver

THE basic histones and the acidic proteins constitute all the protein components of the mammalian chromosomes. Although histones have been suggested as possible gene regulators, the functions of these protein components in relation to genetic activity are still poorly understood. It has, however, been suggested that the acidic proteins may be involved in the biosynthesis of DNA<sup>1</sup>. We reported previously that some of the activity of the calf thymus DNA-polymerase is associated with chromatin proteins<sup>2</sup>. With the isolation of the chromatin acidic proteins from rat liver<sup>3</sup>, a direct test of this suggestion is possible. In this communication we report the partial purification of a DNA-polymerase from the solubilized chromatin acidic proteins of rat liver. Results from the study of this chromatin enzyme show that it depends on a complete supplement of four deoxynucleoside triphosphates for its optimal activity and preferentially uses native DNA as the template.

The non-histone chromosomal proteins were prepared as described previously<sup>3</sup>. Rat liver nuclei, isolated and purified according to the method of Chauveau *et al.*<sup>4</sup> as described elsewhere<sup>5</sup>, and rid of the nuclear sap proteins by repeated extractions with *tris* buffer, were extracted with 1 molar sodium chloride to obtain the DNA-protein complex. The extract was diluted to 0.14 molar with respect to sodium chloride, whereupon DNA-histones recombined and precipitated, while the non-histone chromosomal proteins, referred to as the chromatin acidic proteins, remained in the solution. The chromatin acidic proteins thus obtained were precipitated at 80 per cent saturated ammonium sulphate and collected by centrifugation. The pellet (Fraction III) was successively extracted with 60 per cent and 30 per cent saturated ammonium sulphate containing 1 mmolar potassium phosphate buffer, pH 8.0, and 1 mmolar 2-mercaptoethanol. The extract obtained by 30 per cent saturated ammonium sulphate (Fraction IV) was dialysed against the mercaptoethanol-phosphate buffer and absorbed on a hydroxylapatite column. The protein was eluted with a linear gradient of 0.001–0.3 molar potassium phosphate buffer, pH 8.0, containing 1 mmolar mercaptoethanol. Each chromatographic fraction was then assayed for its activity of incorporating tritiated TTP into DNA. The active fractions, eluted between 0.15–0.2 molar phosphate, were pooled (Fraction V) and used as the partially purified DNA-polymerase for the experiments described here.

DNA-polymerase activity was assayed essentially according to the procedure of Mantsavinos<sup>6</sup>. The reaction mixture contained in a volume of 0.5 ml.: 20  $\mu$ moles of glycine buffer, pH 8.0; 5  $\mu$ moles of magnesium chloride; 0.5  $\mu$ moles of 2-mercaptoethanol; 50  $\mu$ g of calf thymus DNA, prepared according to Thomas *et al.*<sup>7</sup>; 20  $\mu$ moles each of dATP, dCTP, dGTP and TTP, one of which was labelled with radioactivity; and 0.05–0.1 mg of the enzyme. The reaction mixture was incubated at 37° for 1 h. At the end of the incubation, the mixture was chilled in ice-water, and 0.3 mg of bovine serum albumin was then added as carrier to the reaction mixture, followed by 0.1 ml. and 2.5 ml. of cold 50 per cent and 5 per cent trichloroacetic acid, respectively. The acid-insoluble precipitate was collected on a 'Millipore' filter (0.45  $\mu$  pore size), washed five times, through filtration with 5 ml. of cold 5 per cent trichloroacetic acid, and counted in a Packard scintillation spectrometer. The counts obtained were corrected for zero-time absorption. Protein concentration was measured from absorbancies at 2800 Å and 2600 Å according to Layne<sup>8</sup>.

Table 1 shows the purification steps for the DNA-polymerase. Using this procedure, a 250-fold purification of the enzyme has been achieved from the starting liver homogenate. Assay of nuclear sap for DNA-polymerase

Table 1. PURIFICATION OF RAT LIVER CHROMATIN DNA-POLYMERASE

Fraction	Specific activity $\mu$ moles tritiated TTP/mg protein
Liver homogenate	0.025
Nuclei	0.26
III Chromatin acidic proteins	0.96
IV Ammonium sulphate	3.6
V Hydroxylapatite	5.2

Table 2. INCORPORATION OF LABELLED DEOXYNUCLEOSIDE-5'-TRIPHOSPHATES INTO DNA

	$\mu$ moles labelled deoxynucleoside triphosphate incorporated	
	Fraction IV	Fraction V
1. Complete system ( $^3$ H-TTP)	476	403
-dATP, -dCTP, -dGTP	290	72
2. Complete system ( $^3$ H-dATP)	503	415
-dCTP, -dGTP, -TTP	138	77
3. Complete system ( $^3$ H-dCTP)	523	317
-dATP, -dGTP, -TTP	342	130
4. Complete system ( $^{14}$ C-dGTP)	446	444
-dATP, -dCTP, -TTP	326	213

activity gave only 10 per cent of that of the chromatin acidic proteins. Partial purification of the enzyme is shown further by the increased dependence of the polymerase system on a complete supplement of all four deoxynucleoside triphosphates (Table 2). The polymerase thus obtained is about three times more active than the DNA-polymerase purified from the soluble proteins of rat liver<sup>9</sup>. The incorporation of isotopic deoxynucleoside triphosphates in the absence of the other three nucleotides suggests some terminal addition activity possibly resulting from 3' —OH termini produced by an endogenous nuclease. The results are, however, comparable with other mammalian preparations.

Table 3. CHARACTERISTICS OF THE RAT LIVER CHROMATIN DNA-POLYMERASE

	Tritiated TTP incorporated ( $\mu$ moles)
1. Complete system	337
2. - DNA, + heat-denatured DNA*	201
3. - DNA	0
4. + Actinomycin D, 100 $\mu$ g	44
5. Complete system, DNA pre-incubated with 50 $\mu$ g DNase	0
6. Complete system, post-incubated with 50 $\mu$ g DNase for 1 h	0
7. Complete system, post-incubated with 50 $\mu$ g RNase for 1 h	300

\* Heat-denatured DNA was prepared by heating 50  $\mu$ g of native DN at 100° C for 10 min and rapidly cooling in ice-water.

That the rat liver chromatin enzyme is characteristic of DNA-polymerase is shown in Table 3. It can be seen that incubation of the labelled reaction product with DNase renders the incorporated radioactivity acid-soluble; whereas treatment with RNase is ineffective. This indicates a DNA-like product. The polymerase-catalysed incorporation of tritiated TTP has an absolute requirement for DNA template. When actinomycin D was included in the reaction mixture, 87 per cent of the incorporation activity for tritiated TTP was abolished. This suggests that the chromatin DNA-polymerase is essentially of the replicative type. Although the enzyme can utilize either native or heat-denatured DNA as the template, it shows a preference for the double-stranded molecule (Table 3). This template specificity is similar to that of the DNA-polymerase purified from rat liver soluble proteins<sup>9</sup>, but differs from the DNA-polymerases of calf thymus<sup>10</sup> and ascites tumour cells<sup>11</sup> which preferentially utilize heat-denatured DNA as template.

DNA-polymerases isolated from various animal tissues and tumours seemingly are not identical with regard to their intracellular localization and the physical state of the DNA template required. Although in bacteria the enzyme has been observed to be associated with DNA<sup>12,13</sup>, most of the mammalian polymerase preparations have been obtained from the soluble proteins of the cell<sup>6,10,14</sup>. Exclusive localization of DNA-polymerase activity in the cell nucleus, however, has been observed in sea urchin embryos<sup>15</sup>, cells which undergo rapid division. In view of the template requirement, it is logical to expect the association of this enzyme with the chromosomal complex

where DNA replication takes place. The partial purification of the DNA-polymerase from the chromatin acidic proteins thus directly demonstrates the chromosomal origin for the enzyme. Perhaps more significantly it shows that one of the functions of the non-histone chromatin acidic proteins is its participation in the biosynthesis of DNA.

### Ornithine Carbamoyltransferase Activity in Plasma of Mice with Malaria as an Index of Liver Damage

INCREASED concentrations of glutamic oxalacetic and glutamic pyruvic transaminases have been detected in the serum of mice infected with *Plasmodium berghei*, and they are thought to be connected with changes in the liver<sup>1-4</sup>. Transaminases, however, are found in tissues other than liver<sup>5</sup> and are present in high concentrations in erythrocytes. Thus in clinical disorders associated with haemolysis, such as malaria, enzyme from lysed erythrocytes may contribute significantly to serum concentrations<sup>2</sup>.

An increase in carbamoyltransferase (OCT) in the serum reflects liver injury because this enzyme is usually found almost exclusively in the liver<sup>6-11</sup>. Normally, OCT occurs only in small amounts in blood serum, and haemolysis itself, *in vitro* or *in vivo*, does not increase the OCT in the serum<sup>10,11</sup>. The distributions of OCT in various organs of man, the dog and the mouse are similar; the liver shows extremely high activities, the small intestine much less, and other organs only traces of activity<sup>11</sup>. Increases of serum OCT have been demonstrated in a variety of liver disorders of man<sup>8,10,12,13</sup> and after induced liver injury in the dog<sup>7</sup> and the mouse<sup>14</sup>. Study of OCT in the plasma in malaria and other parasitic infections has, however, not been reported, and so we have assayed plasma OCT activity (P-OCT) in mice injected with *P. berghei*.

We assayed P-OCT in mice for 6 days after their inoculation with NYU-2 strain of *P. berghei* maintained through repeated mouse passages. Inocula were prepared by the method of Hillyer and Diggs<sup>15</sup>. ICR donor mice, infected 3 days before with approximately 10<sup>7</sup> parasitized erythrocytes, were exsanguinated, and blood was pooled in ice-cooled sodium citrate. A sample from the pool was withdrawn for the parasites to be counted, and to the rest citrate solution was added to a concentration of about 10<sup>7</sup> parasitized RBC/0.2 ml.

A group of young ICR mice, weighing 15-20 g, was divided into an experimental and a control group. Mice

were freely given baked biscuits and water at all times. All experimental mice were injected peritoneally with  $10^7$  parasitized RBC from the same donor pool and at the same time. On the same morning, control mice were injected intraperitoneally with 0.2 ml. of a similar suspension of non-parasitized erythrocytes derived from non-infected *ICR* donor mice.

Blood for individual determination of parasitaemia and/or P-OCT was obtained concurrently from randomly selected groups of control and experimental mice on each of the 6 days after inoculation. Mice were anaesthetized with carbon dioxide, and exsanguinated by direct heart puncture with pre-heparinized syringes. Heparin does not interfere with OCT assay<sup>10</sup>.

Blood specimens were centrifuged immediately, plasma samples were separated, and chemical analyses were performed immediately after collection<sup>10</sup>.

Baseline plasma citrulline concentration, and that produced by the activity of OCT, were assayed by the method of Ceriotti and Gazzaniga<sup>18</sup>. To measure absorbance, we used the Gilford modification of the Beckman DU spectrophotometer, with rectangular microcells of 10 mm light path.

Parasitaemia levels were determined by thin blood smears stained with Giemsa stain, and the degree of parasitaemia was determined by examining 200 or more erythrocytes and was expressed as percentage of cells parasitized.

On each of 6 days the P-OCT values in infected mice were higher than in controls (Table 1). The differences in mean P-OCT values between infected and control mice were statistically significant ( $P=0.01$  or less) on all days except the second. P-OCT values of infected mice on the fifth and sixth days after inoculation were about five times those of the corresponding control mice. The levels of parasitaemia increased with time after inoculation. As the mean levels of parasitaemia of the groups increased, so did the percentage increases of total plasma citrulline and P-OCT over those of the corresponding control groups (Table 1). Increase in P-OCT after inoculation was in approximate chronological agreement with the development of histopathological changes previously noted in the livers of both germ-free and conventionalized *ICR* mice infected with *P. berghei*<sup>4</sup>. For example, hepatocellular fatty metamorphosis began on the third day, and both numerical increase and hypertrophy of Kupffer cells began on the third or fourth day. Small but distinct increases of P-OCT occurred, however, during the first 2 days of infection, suggesting that hepatocellular derangement occurs before structural damage is detectable by conventional histopathological methods.

There was no significant difference between basal plasma citrulline concentrations in infected and non-infected mice, and no significant change occurred in the infected mice.

Basal citrulline was not essential for detecting increased P-OCT in the malarious mice. This is shown by the increases of total plasma citrulline (Table 1), which include both basal citrulline and the citrulline produced from the ornithine substrate by OCT during incubation. Thus, the relative increases in total plasma citrulline reflect adequately the progressive increases in P-OCT during the course of malaria.

As mentioned, lysis of non-parasitized erythrocytes does not result in an increase in serum OCT activity. Rather, it has been reported that "massive haemolysis" results in a small decrease, presumably by dilution<sup>10</sup>; this contrasts sharply with the eight-fold increase in activity of serum glutamic oxalacetic transaminase which follows haemolysis of whole blood, for example, with water<sup>17</sup>. Nevertheless, in order to ensure that rupture of erythrocytes parasitized by *P. berghei* did not directly contribute to the increase in P-OCT, we devised an *in vitro* test to provide a more extreme lysis than is usual with malaria. This involved intentional disintegration of the erythrocytes and the parasites from infected mice, and we could determine whether the presence of parasite and/or erythrocyte components free in the plasma altered the results of the P-OCT assay.

Using the same materials and methods as described, we infected a separate group of five male *ICR* mice with  $10^7$  parasitized RBC. Three days later the mice were anaesthetized with carbon dioxide and exsanguinated by heart puncture with pre-heparinized syringes. The blood was handled carefully to avoid haemolysis. The blood specimens were pooled, and a stained smear showed that approximately 30 per cent of the RBCs were parasitized. The pooled whole blood was divided into two equal portions. One portion was centrifuged, and the clear, apparently unhaemolysed plasma was collected to assay its OCT activity. The rest of the whole blood was passed twice through a pressure cell<sup>18</sup>, operated at 20,000 lb/in.<sup>2</sup> in a 4° C cold room. A stained thin smear revealed virtually no intact host cells or parasites and centrifugation yielded a clear and very red supernatant portion; only a small pellet of cellular debris remained as the sediment. The haemolysed and non-haemolysed preparations were simultaneously assayed for OCT, and yielded values, respectively, of 41 and 58 units, as defined in Table 1. Thus, even after massive haemolysis and parasite damage we found only a slight, insignificant decrease in OCT. This agrees with the evidence that haemolysis slightly lowers the concentration of P-OCT. It is evident, then, that the marked elevation of P-OCT observed in infected mice is not directly related to haemolysis and/or to the presence of the parasite or its components in the assayed plasma.

Maegraith<sup>2</sup> has recently summarized some of the experimental evidence for the occurrence of mitochondrial

Table 1. P-OCT ACTIVITY OF *ICR* MICE DURING THE FIRST 6 DAYS OF *P. berghei* INFECTION

Time mice observed (day)	No. of mice	Parasitaemia (%)	Plasma citrulline	Percentage difference between C and E total citrulline (%)	P-OCT activity (units)	Percentage difference between C and E P-OCT activity (%)
	C	E	Basal* (μmoles/100 ml.)		C	E
			C	E		
1	10	10	25	23	69 ± 3.0	83 ± 3.7 ‡
2	10	10	22	22	54 ± 8.0	78 ± 14.0
3	10	10	25	25	27 ± 0.4	76 ± 15.6 †
4	10	10	12	15	41 ± 13.0	132 ± 18.0 †
5	10	10	31	36	17 ± 6.9	114 ± 22.5 †
6	7	6	11	27	52 ± 10.6	304 ± 29.2 †
1-6	57	56	21	25	43	131

Experimental mice (E) were infected by intraperitoneal injection of 0.2 ml. of a suspension containing about  $10^7$  parasitized erythrocytes; control mice (C) were similarly injected with 0.2 ml. of a normal, non-parasitized erythrocyte suspension. P-OCT units represent μmoles of citrulline produced/100 ml. of plasma after incubation with L-ornithine substrate at 37° C for 1 h; the production of citrulline *in vitro* is calculated from the total citrulline by subtraction of the basal (preformed) citrulline, assayed on another aliquot of the same plasma specimen. The percentages of the differences between the E and C values are calculated as follows:

$$\frac{(E-C)}{C} \times 100$$

Blood parasite levels are expressed as the percentage of parasitized erythrocytes from 200 (or more) cells examined. Values given are the means, alone or ± the standard error of the mean.  
\* Before incubation. † After incubation. ‡ Difference between mean values of C and E is statistically significant at  $P=0.01$  or less, as determined by Student's *t* test.

dysfunction in liver cells in malaria. In view of our present finding of striking elevations of P-OCT in infected mice, it is pertinent that OCT is found in liver mitochondria<sup>6,19</sup>. Thus, elevated P-OCT may reflect hepatocellular involvement at the level of the mitochondrion. If malaria infection results in dissolution of the well known interdependent structural and functional integrity of this hepatic organelle, then the release of OCT from this source may account for the rise in P-OCT that we observed. The mechanism by which malaria infection produces elevation in P-OCT and the full clinical significance of this finding remain to be determined. Maeraith<sup>2</sup> has pointed out that bilirubin can initiate, in certain circumstances, mitochondrial damage similar to that which he has observed in malaria. Mice infected similarly to ours showed, however, only minor and inconsistent changes in total serum bilirubin<sup>3</sup>, and there was no evidence of obstructive or other changes in the hepatobiliary tree<sup>4</sup>.

If laboratory primates and man also show significant increases in P-OCT during malaria infection, measurement of P-OCT may be useful in the prognosis and diagnosis of malarial infections and in the evaluation of the efficacy of antimalarial agents.

### Chemical Coupling of Proteins to Agarose

WE have reported a method for transforming polysaccharides into reactive derivatives useful for coupling proteins to carbohydrates<sup>1</sup> which consists in treating the polysaccharide with cyanogen halide. Imino carbonic acid esters are probably formed and these react with the primary amino groups of proteins and other substances. This method of activation and coupling is gentle and therefore particularly useful for the production of immunosorbents and insoluble enzymes.

The biological activity of enzymes, hormones and antibodies is much decreased when these proteins are chemically attached to the matrix of, for example, cellulose and 'Sephadex'. The interaction between the fixed proteins and solutes of specially large molecular weight is obviously sterically strongly impeded. When such interactions are important (for example, in antigen-antibody reactions and for enzyme degradation of proteins) the adsorbents

or insoluble enzymes should be prepared from a matrix of a more open structure.

Agarose was considered to meet the required demands. In the bead form agarose gels prepared according to Hjertén<sup>2</sup> give beds with good flow properties which are retained even after coupling. The cyanogen halide activation method is mild enough to allow the necessary reactions to take place without destroying gel particles. Agarose is composed of residues of anhydrogalactose and galactose rather than of glucose, and so crosslinking is likely to be less important.

In the test of agarose as a coupling partner for proteins, chymotrypsin was chosen and its activity before and after coupling was compared. Agarose beads were prepared from 1 per cent, 2 per cent and 12 per cent agarose solutions, and suspensions of these were prepared containing 3, 10 and 40 mg of agarose/ml. respectively. At room temperature a solution containing 25 mg of cyanogen bromide/ml. (2 ml.) was added to a volume of agarose suspension corresponding to 50 mg agarose in a small container. The pH was rapidly adjusted to 11 and kept constant for 6 min by continuous addition of 2 molar sodium hydroxide using an automatic titrator. The reaction mixture was gently stirred during the process. The gel was immediately washed on a glass filter with ice water, followed by 0.1 molar sodium hydrogen carbonate solution. The activated product was immediately used for the coupling and was for that purpose transferred to a test-tube. A 0.1 molar solution of sodium hydrogen carbonate (11 ml. for 1 per cent agarose, 2 ml. for 2 per cent agarose and 1.5 ml. for 12 per cent agarose) and 25 mg of chymotrypsin were added. The tube was closed and slowly rotated end over end for 20 h at 5° C. The reaction product was very carefully washed in a small column at a rate of 8 ml./h with the following solutions in the order indicated: 0.1 molar sodium borate of pH 8.5 containing 1.0 molar sodium chloride (48 h); 0.1 molar sodium acetate, pH 4.1, containing 1.0 molar sodium chloride (24 h); and finally with 0.01 molar sodium acetate buffer (24 h). A small portion of the gel was prepared for determination of protein by washing with water and then followed by acetone followed by drying. In a similar test with a mixture of chymotrypsin and agarose including all washings no residual absorption of chymotrypsin to the gel was detected.

As blanks for enzyme assay, chymotrypsin and unreacted agarose were mixed and kept in the same conditions as the gel. Esterolytic activity was determined, using *N*-acetyl-L-tyrosine ethyl ester as a substrate. The appropriate amount of coupled chymotrypsin-agarose gel or corresponding free enzyme was added to the substrate solution and the formation of acid was recorded by a titrator. The titration was made at 23° C under nitrogen. Samples of gel suspensions were pipetted out, and proteolytic activity was determined with casein as substrate<sup>3</sup>. The pH optima and the activity ratios for the bound and free enzyme at the optima were determined (Table 1).

To test the stability, chymotrypsin-agarose gel was kept in 0.01 molar acetate solution, pH 4.1, for 2 months at room temperature, then washed for 2 days with 0.1 molar borate buffer, pH 8.5, containing 1 molar sodium chloride. No loss in activity was observed.

The tightness of the gel greatly influences the coupling yield as well as the activity. A tight gel may give a high degree of coupling, but the activity will be lower and the pH optimum is displaced farther than for looser gels. The decrease in activity as a function of the concentration of the matrix is pronounced for casein, which would be expected from sterical hindrance of large molecular size substrates.

The high degree of activity retained in the loose agarose-chymotrypsin gels is noteworthy and makes this a very promising general method for coupling solutes of large molecular size to an insoluble matrix. The chymotrypsin-agarose gel has been used in a series of bed experiments

Table 1. CHEMICAL BINDING OF CHYMOTRYPSIN TO AGAROSE GELS IN BEAD FORM; DETERMINATION OF ENZYME ACTIVITY TOWARD N-ACETYL-L-TYROSINE ETHYL ESTER AND CASEIN

Agarose concentration in the gelation solution (per cent)	Amount of bound protein (mg of protein/g of dried conjugate)	Coupling yield based on added amount of protein (per cent)	pH optimum	Esterolytic activity Activity ratio bound to free enzyme (per cent)	Proteolytic activity pH optimum	Activity ratio bound to free enzyme (per cent)
1	130	30	9.6	50	7.9	45
2	175	42	10.0	45	8.0	35
12	310	90	10.0	50	8.7	10

pH optima for free chymotrypsin toward N-acetyl-L-tyrosine ethyl ester and casein were 7.9 and 8.0 respectively.

("bed reactor") for a wide pH range, and no decrease in activity was seen. Human immunoglobulin of  $\gamma$ G-type has been coupled to agarose in similar conditions. Agarose- $\gamma$ G-gels containing about 350 mg of protein/g of conjugate were obtained.

We thank Dr Stellan Hjertén for agarose gels and for valuable advice. This work was supported by the Swedish Technical Research Council and the Swedish Foundation for Scientific Research and Industrial Development.

### Possible Cytotoxic Role of Nitrenes

THERE is increasing evidence that the N-oxide structure may be concerned with damage to proliferating cells of a kind which is reflected in carcinogenesis and/or tumour inhibition. Among the compounds recorded in the literature in this respect are 2-N-hydroxyacetamidofluorene<sup>1,2</sup>, 4-N-hydroxyacetamidodiphenyl<sup>3</sup>, 2-N-hydroxyamino-naphthalene and its N-acetyl derivative<sup>1,4</sup>, N-hydroxyurea<sup>5,6</sup>, N-hydroxyurethane<sup>7</sup>, N-hydroxyoxamide and its O-acetyl derivatives<sup>6</sup>. It is now suggested that many of the experimental biological observations may have a common basis, connected with the chemistry of the nitrene (imidogen) group. The purpose of this communication is to draw attention briefly to the manner in which reactive derivatives of this class may be generated, and to speculate on their possible mode of interference with cell structures.

Nitrenes have the general form  $R-\ddot{N}:$ , that is, they show an electron deficient nitrogen atom carrying a sextet of electrons in its outer shell. They are formed, or have been postulated as intermediates (not without controversy), in a number of reactions such as the Curtius, Lossen, Beckmann and Hofmann re-arrangements, so that  $R$  can be said to include H, alkyl, aryl, acyl, sulphonyl, phosphoranyl or amino. They are therefore capable of being generated in a number of ways, but in the present context only two may be relevant. The first involves the abstraction of the molecular species  $R'OH$  from a hydroxylamine derivative; thus  $R-NH-OR' \rightarrow R-\ddot{N}:$ . For example, the chemical reactivity of  $EtO.CO-\ddot{N}:$  has been conveniently studied by its preparation *in situ* through the interaction of triethylamine and the *p*-nitro-sulphonic acid ester derived from N-hydroxyurethane ( $R' = -SO_2.C_6H_4.NO_2$ ). The second experimental preparative method is through oxidation of an amine or amide; thus  $R-NH_2 \xrightarrow{O} R-\ddot{N}:$ . Where  $R$  is acyl, further re-arrangements may occur, as in the oxidation of amides by lead tetra-acetate.

Some of the compounds listed above have been isolated as metabolites after the administration to various animals of the corresponding amines or amides, but from the literature it is not always unequivocally certain whether the manifestations of cytotoxicity *in vivo* are caused by

the parent compound, or its oxidation product, or indeed both. It is now postulated that a nitrene may in fact be the biologically active species, and that this may be generated either as an intermediate step during the metabolic oxidation of the parent amine or amide (for example, route *a*, when  $R$  might be 2-naphthyl) or, by contrast, arise from the already formed N-hydroxy compound or a further metabolic conjugate (for example, route *b*, when  $R'$  could be sulphato or glucuronido).

If the possible enzyme formation of nitrenes in a biological environment is conceded, it is not difficult to foresee how the disorganization of normal cellular processes might then follow from the intervention of these labile substances. For example, they combine with ethylene groups to give aziridines and imino groups to yield hydrazines, with benzene to give azepines (insertion reactions), with aliphatic hydrocarbons to yield alkylamines, and possibly with thio-ethers to form sulphilimines. It can therefore easily be seen how the close juxtaposition within the cell of a nitrene precursor and a nucleic acid strand, for example, could lead to new covalent bond formation as is supposed for the cytotoxic alkylating agents, and with similar sequelae.

### Specific Inactivation of Pepsin by Benzyl-oxycarbonyl-L-Phenylalanyldiazomethane

THE report by Delpierre and Fruton<sup>1</sup> on the inactivation of pepsin by L-1-diazo-4-phenyl-3-tosylamidobutanone catalysed by copper ions prompts us to report our results on the inactivation of pepsin by benzyl-oxycarbonyl-L-phenylalanyldiazomethane (ZPDM)

which combines with the enzyme in a 1:1 molar ratio. Our results agree with those of Delpierre and Fruton<sup>1</sup> except that copper ions are not essential for the inactivation of pepsin by ZPDM (compare ref. 2). In addition, we observed that during the attachment of ZPDM to pepsin the optical rotatory properties of the enzyme change in a way similar to that observed for heat-inactivated pepsin<sup>3</sup>.

Crystalline *N*-benzyloxycarbonyl-L-phenylalanine acid chloride (3.9 mmoles) prepared by the procedure of Bergmann *et al.*<sup>4</sup> was added to an ice chilled anhydrous ethereal solution of diazomethane (9 mmoles). After standing, the solvent and excess reagent were removed *in vacuo*. The residue was washed with saturated sodium bicarbonate and water and crystallized from petroleum ether and anhydrous diethylether as yellow crystals (0.41 g, 31 per cent yield), melting point 84–85° C with an infra-red band at 4.77 $\mu$ .

$C_{18}H_{17}O_3N_3$  (323.4)

Calculated: C 66.86, H 5.30, N 13.00

Found: C 67.00, H 5.48, N 11.89

Porcine pepsinogen (lot PG S6GA) and crystalline pepsin (lot 637), Worthington, with 14.60 and 14.84 per cent N, respectively, and the amino-acid composition reported elsewhere<sup>5,6</sup> were used, in addition to pepsin freshly prepared from pepsinogen<sup>7</sup>.

For the reaction of ZPDM with the enzyme 0.2 ml. of ZPDM (2 mg/ml.) in methanol was added to 2.0 mg of pepsin in 1.8 ml. of 0.04 normal sodium acetate buffer, pH 5.16. The reaction mixture was kept at 25° C, and the inactivation in the presence and absence of copper ions was followed by the haemoglobin method of Anson<sup>8</sup>. Thus, at a molar ratio of ZPDM/pepsin = 5 the first order rate constant,  $k$ , in the presence of 1.0 mmolar copper ions is  $1.37 \times 10^{-2} \text{ sec}^{-1}$ ; in the absence of copper ions,  $k = 3.92 \times 10^{-6} \text{ sec}^{-1}$ .

As shown in Fig. 1, pepsin has a pH activity optimum at 1.8 but inactivation of the enzyme occurs at pH 5.3–5.6. ZPDM was stable in our experimental conditions. Thus its inertness toward pepsin at pH 1.0–3.5 cannot be ascribed to instability. Considering that a  $\beta$ -carboxyl of an aspartic acid residue has been implicated as the site of attachment of active site inhibitors to pepsin<sup>9–11</sup>, such a residue with an unusual high  $pK$  may explain the pH optimum of inhibition by ZPDM (ref. 12).

To confirm that in the absence of copper ions ZPDM combines in a 1:1 ratio, a reaction mixture containing a 10 molar excess of ZPDM/mole of pepsin was passed over a 'Sephadex G-25' column, 0.9  $\times$  20 cm, using 0.04 normal acetate buffer, pH 5.04, in 10 per cent methanol and the absorption at 276 m $\mu$  (ref. 2). Inactive pepsin (26.5  $\mu$ mole) 25.0  $\mu$ mole of which was bound to ZPDM was recovered giving a ratio of ZPDM:protein of 0.94.

Fig. 1. Dependence on pH of pepsin activity and of inactivation of pepsin by ZPDM. Reaction mixtures were 1 mg/ml. of pepsin in 0.04 normal sodium acetate in methanol at various pH values; 0.20 mg/ml. of ZPDM in the absence of copper ions and 0.05 mg/ml. of ZPDM in the presence of 1 mmolar cupric nitrate. Incubation times were 45 min and 1.5 min respectively.

Fig. 2. Far ultra-violet rotatory dispersion of pepsin (○) and ZPDM-pepsin (●) in 0.1 normal sodium acetate buffer, pH 4.9. Arrow indicates the Cotton effects found for wavelength 260–290 m $\mu$ . Protein concentration was 0.025 per cent pepsin and 0.021 per cent ZPDM-pepsin.

The optical rotatory dispersion of ZPDM-pepsin was recorded from 600–200 m $\mu$  in a 'Cary 60' spectropolarimeter. In the spectral region of 600–350 m $\mu$ ,  $[\alpha]$  fits a one-term Drude equation and  $\lambda_c$  is obtained from the plot of  $[\alpha]$  versus  $[\alpha] \cdot \lambda^2$ . As shown in Table 1,  $[\alpha]_{365}$  of ZPDM-pepsin is more laevorotatory and  $\lambda_c$  increases from 217 to 227 m $\mu$ . With both proteins a negative Cotton effect is observed at 225–227 m $\mu$ . In ZPDM, however, the small positive Cotton effect at 260–290 m $\mu$  has disappeared (Fig. 2). As discussed elsewhere, an increase of  $\lambda_c$  from 217 to 227 m $\mu$  is characteristic for heat-inactivated or alkali-denatured pepsin<sup>3,13</sup>. Similarly, changes of the optical rotatory dispersion in the far ultra-violet as those described here take place if the macromolecular conformation of pepsin is altered<sup>14</sup>. Thus we conclude that if ZPDM reacts with a certain amino-acid residue of the polypeptide chain segment necessary for the biological activity of pepsin, that is with its active site, a conformational transition to a less stable conformation takes place which may be accompanied not only by a loss of the enzyme activity but also by a change of the optical rotatory dispersion parameters.

Table 1. SPECIFIC OPTICAL ROTATION AND ROTATORY DISPERSION OF PEPSIN-INHIBITOR AND OF PEPSIN IN 0.1 NORMAL ACETATE BUFFERS

Protein	pH	$-\alpha_{365}^*$	$-\alpha_{365}^*$	$\lambda_c$ (m $\mu$ )	Relative specific activity (per cent)
ZPDM-pepsin	4.3	104	251	225	Not measured
	4.6	102	249	227	6.3
	4.9	105	253	227	6.3
	5.3	98	243	225	5.0
	5.6	109	257	228	5.1
Pepsin	4.6	94	240	218	98.8
	4.9	95	233	218	100.5
	5.3	95	228	217	88.4
	5.6	97	233	217	96.5

The relative specific activity of a freshly prepared pepsin solution in 0.1 normal sodium acetate of pH was taken as 100.

\* Corrected for the refractive index of the solvent.

In summary, the use of substrate-like irreversible inhibitors affords an important tool for the identification of an amino-acid residue involved in the catalytic process<sup>9–11,15–18</sup> and gives information about the conformational changes accompanying interaction of substrate and enzyme.

We thank Dr Guenther Schoellmann for his help and Miss Rosemary DiGaetano and Mrs Kärt Grizzuti for

technical assistance. This work was supported by a grant from the US Public Health Service.

### Relation between Thrombosis on Metal Electrodes and the Position of Metal in the Electromotive Series

INTEREST in the electrochemical nature of thrombosis<sup>1,2</sup> has prompted us to study thrombus deposition on metal electrodes inserted through side branches into the carotid and femoral arteries of mongrel dogs. Magnesium, aluminium, cadmium, nickel, copper, gold and platinum, which cover a wide range in the electromotive series, were chosen for the present investigation.

The electrodes were carefully cleaned to ensure the absence of any oxides or other impurities on their surfaces, and their spontaneous potentials were measured in normal (0.9 per cent) saline solution. In the first series of experiments four electrodes of the same metal were inserted through side branches into the carotid and both the femoral arteries in healthy anaesthetized (1/2 ml/kg of 'Diabital' intramuscular injection) mongrel dogs; care was taken to prevent injury to the intimal surface. The spontaneous potential set up by each of these electrodes, after their insertion, was measured with respect to a standard calomel electrode (contained in a beaker with saturated potassium chloride solution). An electrolyte bridge was made between the experimental animal and the beaker containing the calomel electrode by inserting a fine polyethylene tubing into a second branch of one of the femoral arteries. The back flow of blood into this tubing was allowed to clot. The electrodes were kept in position within the lumen of the arteries for a period of 30–40 min.

The dog was killed and the four vessels containing the electrodes were gently clamped both proximally and distally, so as to include the electrode, but without disturbing the position. Formalin was then slowly injected into the portions of the blood vessels between clamps so as to fix any deposits of thrombi on the electrodes. Finally, the vessels were gently slit open and the electrodes within these were examined for any thrombus deposition.

The results were striking. Electrodes of metals establishing a negative interfacial potential (NHE), magnesium, aluminium and cadmium, showed no thrombus deposition (on their electrodes), whereas metals with a positively

charged surface—copper, nickel, gold and platinum—showed a measurable deposition of thrombus along the length of the electrode. The interfacial potentials set up by metals in contact with blood *in vivo*, their corresponding standard electrode potentials and the occurrence or otherwise of thrombus deposition on their surfaces, are summarized in Table 1. As expected, there is a direct correlation between the spontaneous potentials set up by these metals in blood *in vivo* and their respective standard electrode potentials.

Table 1. DEPENDENCE OF THROMBUS DEPOSITION AT METAL ELECTRODES ON POSITION OF METAL IN ELECTROMOTIVE SERIES

Metal	M/M <sup>0+</sup> standard electrode potential (V, NHE)	Resting potential at metal-blood interface (V, NHE)	Occurrence (✓) or non-occurrence (×) of thrombus deposition
Mg	-2.375	-1.360	×
Al	-1.670	-0.750	×
Cd	-0.402	-0.050	×
Cu	+0.346	+0.025	✓
Ni	-0.230	+0.029	✓
Au	+1.420	+0.120	✓
Pt	+1.200	+0.125	✓

In an attempt to confirm these results further, experiments were carried out using electrodes of two different types of metals, one on the electropositive, and the other on the electronegative side. These were inserted into ipsilateral, carotid and femoral arteries in the same animal in the conditions of the previous experiments. The results confirmed the earlier set.

The present series of experiments conclusively proves that thrombus deposition on metals *in vivo* depends, at least partly, on the interfacial potential. The more positively charged interfaces are thrombogenic; those negatively charged are non-thrombogenic. These findings are of considerable fundamental importance in the search for suitable non-thrombogenic surfaces for incorporation into various artificial internal organs.

### Psychotropic Phenylisopropylamines derived from Apiole and Dillapiole

It is an interesting fact that most of the known psychotropic phenylisopropylamines (amphetamines) possess ring-substitution patterns identical to those of natural essential oils. (The single exception is the active 2-methoxy-4,5-methylenedioxyamphetamine (MMDA-2, II<sup>d</sup>); neither the allyl nor the propenyl counterpart has been observed in plant extracts.) Thus 3,4-methylenedioxyamphetamine (MDA, II<sup>a</sup>) is related to saffrole (II<sup>a</sup>)<sup>2</sup> (Table I), 3,4,5-trimethoxyamphetamine (TMA) to elemicin<sup>3</sup>, 3-methoxy-4,5-methylenedioxyamphetamine (MMDA, II<sup>c</sup>) to myristicin (Ic)<sup>4</sup> (Table I), 2,4,5-trimethoxyamphetamine to asarone, and 2-methoxy-3,4-methylenedioxyamphetamine (MMDA-3a, II<sup>b</sup>) to croweacin (Ib) (Table I). C. F. Barfknecht, of Idaho University, tells us that there is preliminary evidence that these olefines may be aminated in the living organism, and this reaction can be readily performed *in vitro*. There are two additional essential oils known that contain the methylenedioxy ring. These are apiole (Ie) and dillapiole (If) (Table I).

These two naturally occurring aromatic ethers are the two possible ring-methoxylated analogues of myristicin.

We have synthesized the two amphetamines which correspond in structure to these essential oils, that is, 2,5 - dimethoxy - 3,4 - methylenedioxyamphetamine (DMMDA, IIe) and 2,3-dimethoxy-4,5-methylenedioxyamphetamine (DMMDA-2, II f).

Table 1. A COMPARISON OF THE STRUCTURES OF THE NATURAL ESSENTIAL OILS (I) AND THE AMPHETAMINES (II)

	I			II			Potency (mescaline units)
	R <sub>1</sub>	R <sub>2</sub>	R <sub>3</sub>	I	II		
a	H	H	H	Safole	MDA		3
b	OCH <sub>3</sub>	H	H	Croweacin	DMMDA-3a		18
c	H	OCH <sub>3</sub>	H	Myristicin	MMDA		2
d	H	H	OCH <sub>3</sub>	(Unknown)	MMDA-2		21
e	OCH <sub>3</sub>	OCH <sub>3</sub>	H	Apiole	DMMDA		12
f	H	OCH <sub>3</sub>	OCH <sub>3</sub>	Dillapiole	DMMDA-2		5

DMMDA was synthesized directly from apiole (obtained from oil of parsley) using the same sequence of steps (isomerization,  $\beta$ -nitration, and hydrogenation) that was successful in the conversion of myristicin to MMDA<sup>4</sup>. It was not possible to isolate useful quantities of dillapiole, so it was obtained synthetically<sup>5</sup> and converted through the above steps to DMMDA-2.

A threshold intoxication with DMMDA in human volunteers was consistently recognized at about 200  $\mu$ g/kg (calculated as the free base and administered orally as the hydrochloride). With most subjects\* concentrations within the range 250–300  $\mu$ g/kg produced a psychotropic episode with the following chronology. The initial 1–1.5 h, preceding the first indications of mental change, were quite free of the signs of the autonomic distress that have frequently been observed with both mescaline and TMA, but only occasionally within the MMDA series. Mild incoordination marked the start of the intoxication period which lasted 2–4 h. During this interval there were only mild perceptual distortions and, in common with MDA, there were increased generalizations of the thought processes, increased emotional affect and empathy, as well as euphoria and a lack of anxiety. The colour exaggerations of mescaline and the eyes-closed images characteristic of MMDA were absent. The gradual disappearance of this syndrome was complete in 8–12 h and the subjects' recall of these events and interpretations was unimpaired, as has been consistently true with the related amphetamines. The syndrome of DMMDA-2 intoxication was qualitatively similar in nature; the threshold was first observed at 400  $\mu$ g/kg and an effective dose range was established as lying between 600–1,000  $\mu$ g/kg. DMMDA-2 has therefore an activity intermediate between DMMDA and MMDA, the latter being active in the vicinity of 2–2.5 mg/kg.

Two arguments must be considered in any explanation of the activity of compounds such as these. First, it has been suggested that  $\beta$ -phenethylamines may participate in central nervous system metabolism through ring closure with the formation of an indole intermediate. This cyclization has been argued as involving an electrophilic attack by the protonated amine on the aromatic ring. In this manner both epinephrine<sup>6</sup> and the demethylation products of mescaline<sup>7</sup> have been oxidatively

cyclized *in vitro*, although no evidence has appeared to support such reactions *in vivo*. At first appearance this argument is supported by the observation that the addition of a methoxyl group to either of the ortho-positions of MMDA (to produce DMMDA or DMMDA-2) increases the potency of the product *in vivo*. Such substitutions would certainly enhance electrophilic ring closure. Specifically, the dose levels of DMMDA and DMMDA-2 reported here allow assignments of potencies of 12 and 5 mescaline units (MU)<sup>1</sup>, respectively, whereas the trisubstituted counterpart MMDA has a rating of about 3 MU.

An alternate indole synthesis route must also be considered. It will be noted that if the *meta*-methoxyl group were removed from either of these tetrasubstituted amphetamines (so actually reducing its theoretical ease of cyclization) MMDA-3a (IIb) would be obtained from DMMDA, and MMDA-2 (II d) from DMMDA-2, yet both of these simpler bases are of still higher potencies (MU of 18 and 21, respectively). Thus it may not be the presence, but rather the position, of the additional group that leads to an enhanced activity. This latter route would then suggest an interaction of the amino-groups with a quinonic intermediate in which the oxygen atom of the ortho-methoxyl group participates.

A second argument is that several phenolic amines are known to act as neurotransmitters. Methylated and methoxylated analogues might function directly (without chemical modification) either as inhibitors or as false transmitters in the specific neural networks served. On the basis of this hypothesis a psychotomimetic molecule should be resistant to chemical attack, rather than sensitive to it, as would be required for conversion to an indole.

Any attempts to understand the mechanisms of action of these materials must still consider the qualitative distinctions that have been noted, however. The two new psychotropic agents reported here, as is true with the two-oxygen methylenedioxy analogue MDA, exhibit changes in affect and empathy and in general are intoxicants, but they should not be classified as psychotomimetics. It seems that this property occurs, at least among the phenylisopropylamines only in those which are trisubstituted.

## PATHOLOGY

### Effect of Previous Injection of Homologous Embryonic Tissue on the Growth of Certain Transplantable Mouse Tumours

In a previous communication Buttle, Eperon and Menzie<sup>1</sup> reported that injections of suspensions of human embryonic tissues into weanling rats prevented the growth of the transplantable human tumour HS.1 when the

\* All subjects were familiar with the other materials mentioned in these comparisons, MDA, MMDA, DMMDA-3a.

animals were challenged 7 days later with tumour and then conditioned with cortisone. This communication reports similar experiments undertaken to study the inhibition of transplantable mouse tumours by using mouse embryonic tissue.

Mice of several random and inbred strains were used. The mouse tumours used were the imferon induced sarcoma<sup>2</sup>, the Crocker sarcoma S180 and two 20-methyl cholanthrene induced sarcomata, one in BALB/C mice and one in C57 Black/6, obtained from Dr Lloyd Old of the Sloan Kettering Institute. Efforts to induce the imferon sarcoma in a pure line mouse, or in an F1 cross, have so far been unsuccessful.

The embryonic tissues were obtained from mice towards the end of the gestation period. Both embryonic and tumour tissues were minced finely with scalpels and injected subcutaneously with penicillin and streptomycin in 50 per cent suspension by weight of tissue in mammalian Ringer solution.

For imferon (iron dextran) sarcoma induced in random Chester Beatty mice, Table 1 shows the degree of inhibition caused by the injection, 7 days before the tumour implants of 0.5 ml. of 50 per cent suspensions of the liver, and of the placenta from 20 day old foetal mice. As controls mice were injected with similar quantities of a suspension of adult mouse liver. It can be seen that suspensions of foetal liver as well as foetal residues after the removal of the liver are effective in completely inhibiting the tumour growth whereas the placenta and adult mouse liver are less effective.

Table 2 shows the effect of early pregnancy in inhibiting growth of the transplantable sarcoma induced by imferon. The growth is negligible when the tumour is inoculated on the eighth day of pregnancy. The tests were carried out in B.S.V.S. mice, in which the tumour grows well; B.S.V.S. mice were also used as donors of embryonic tissue. The imferon tumour has also been induced in the golden hamster, but in this animal neither pregnancy nor the prior injection of embryonic tissue influenced tumour growth.

Experiments with the Crocker mouse sarcoma S180 (Table 3) show that when a suspension of mouse embryonic liver is injected into mice 7 days before tumour challenge, an inhibitory effect on tumour growth is observed. This effect is, however, never as great as that seen with the sarcoma already mentioned which is induced by imferon; the injected mice show tumours of about half the size of those in the controls. Embryonic thymus appears to be as effective as or more effective than foetal liver. Adult mouse liver has little effect while placental suspension is inactive. Fig. 1 shows that the effectiveness of embry-

onic tissue is more obvious if the criterion used is mouse survival time rather than tumour weight.

Fig. 2 shows that mice which react to embryonic tissue by the production of a large subcutaneous swelling at the site of injection show a greater degree of protection against the tumour than those in which no reactions occur; in the latter, tumour weights do not differ significantly from those in the controls. Furthermore, the degree of tumour inhibition is highest if the interval between tissue injections and tumour challenge is 7 days (Table 4). If, on the other hand, the interval is shorter (for example, 3

days), tumour growth exceeds that in the controls, whereas if the interval is longer than 7 days, the effect is gradually reduced until, after 21 days, there is little difference between injected animals and controls.

While all the foregoing experiments were carried out with mice of different strains as donors of embryonic tissue and as tumour hosts respectively, Table 5 shows that when B.S.V.S. mice are used for both purposes the degree of tumour inhibition is reduced from 49 per cent to 34 per cent.

Table 4. CROCKER TUMOUR S180 IMPLANTED INTO B.S.V.S. MICE AT VARIOUS TIMES AFTER SUBCUTANEOUS INJECTION OF MOUSE EMBRYONIC LIVER TISSUE SUSPENSION FROM MICE OF PARKE'S STRAINS (Six mice in each group)

B.S.V.S.	2.73 ± 0.31	1.79 ± 0.45	34.4
Parke's	2.97 ± 0.2	1.39 ± 0.26	53.2

In other experiments pure line *BALB/C* mice were used both as donors of embryonic tissue and as tumour hosts; two different tumours induced by methyl cholanthrene were used. In these instances the growth of the tumours in the mice injected with embryonic tissue did not differ significantly from that in the controls, nor was there any prolonging of the survival time of the treated animals. Similar results were obtained with one tumour induced with methyl cholanthrene in *C57 Black/6* mice.

The inhibitory effect obtained from the injection of embryonic tissue suspensions, 7 days before tumour implantation, is most marked in the case of the imferon induced sarcoma growing in B.S.V.S. mice. The growth of this tumour is also inhibited if it is implanted in early pregnancy (about the eighth day of gestation). A likely explanation of this phenomenon is the possibility that trophoblast cells are mobilized extensively in the circula-

tion early in pregnancy and that these cells may produce an "immunizing" effect. The presence of such cells has been demonstrated in the human subject by Douglas *et al.*<sup>3</sup> and by Canlas<sup>4</sup>. With the Crocker tumour, on the other hand, growth is much less influenced by the prior injection of embryonic tissue, the effect in this case being further reduced if the mice used as donors of embryonic tissue are of the same strain as those used as tumour hosts. The animals which show the greatest tumour inhibitory response are those in which the reactions to the embryonic tissue are most pronounced.

The growth of twenty tumours induced by methyl cholanthrene in pure line *BALB/C* and *C57 Black/6* mice was not influenced by the previous injection of embryonic tissue, derived from animals of the same inbred strains. In every instance where the inhibitory influence of foetal tissue was displayed this was always more pronounced than when adult tissues were used. This could be the result of an antigenic similarity between embryonic and malignant tissues or, alternatively, of the presence of interfering antigens in adult tissues which could then decrease the tumour inhibitory effect. The fact that the methyl cholanthrene tumours in pure line mice do not respond to the injection of embryonic tissue from the same pure line strains suggests that the effect may be similar to that occurring in the homograft reaction and may occur only when there are genetic differences between the host animal and the embryonic tissue used.

### Effect of Route of Administration on Immunosuppression by DMBA in *CBA* Mice

It has been known for some time that certain chemical carcinogens depress the immune response<sup>1</sup>. When the carcinogen is given neonatally this depression may be long lasting<sup>2</sup>. Stjernswärd has shown that in addition to depressing the serum haemolysin response to heterologous red cells, a number of carcinogens lower the number of antibody forming cells in the spleen as measured by the Jerné technique<sup>3</sup>. No such depression was found in response to non-carcinogenic analogues tested, but whether or not immunological impairment is an integral part of carcinogenesis as suggested by Prehn and Main<sup>4</sup> is not yet known. Tumour-specific antigens have been demonstrated in a variety of chemically induced tumours of both mesodermal and epidermal origin<sup>5,6</sup>. Transformed cells multiplying to form macroscopically recognizable tumours seem to do so despite their antigenicity: they may represent only the proportion of potentially neoplastic cells which have in some way overcome host resistance.

The incidence and sites of tumour production vary with the route of administration of a carcinogen, and it was therefore interesting to see whether immunosuppression induced by a carcinogen is similarly affected. Carcinogenic doses of 9,10-dimethylbenzanthracene (DMBA) were administered orally or subcutaneously to mice, and the subsequent responses to an intraperitoneal injection of sheep erythrocytes were compared.

We used seventy-eight female *CBA/H* mice 6 weeks old, weighing between 15 and 18 g, maintained on a cubed

6	33.3 µg DMBA/g body weight orally in a.g.	5.2 ± 1.1 (11)	6.4 ± 0.8 (12)	7.1 ± 1.1 (12)	—
7	100 µg DMBA/g body weight orally in a.g.	4.3 ± 1.5 (11)	6.1 ± 1.6 (10)	6.5 ± 0.7 (8)	—

Numbers of animals tested are shown in parentheses.

diet (Diet 86, Dixons, Ltd.). They were divided into seven groups which were treated as follows.

Group 1 (six mice) was untreated, group 2 (twelve mice) received 3 per cent aqueous gelatine subcutaneously, group 3 (twelve mice) received 33.3 µg/g body weight (that is, 500 µg/15 g of mouse) of DMBA in aqueous gelatine subcutaneously, group 4 (twelve mice) received 100 µg/g body weight (that is, 1,500 µg/15 g of mouse) of DMBA in aqueous gelatine subcutaneously, group 5 (twelve mice) received 3 per cent aqueous gelatine orally, group 6 (twelve mice) received 33.3 µg/g body weight of DMBA in aqueous gelatine orally, and group 7 (twelve mice) received 100 µg/g body weight of DMBA in aqueous gelatine orally.

DMBA (Koch-Light Laboratories, Ltd.) was suspended by ultrasonication in 3 per cent aqueous gelatine. Neither dose resulted in death or weight loss during preliminary toxicity tests. Before peroral treatment the animals were starved overnight, and the DMBA suspension was passed into the stomach through a cannula. The larger dose was given in approximately 0.4 ml., and the smaller dose in 0.25 ml., of aqueous gelatine, the exact volume being adjusted to give the correct dose/g of body weight for each animal. Subcutaneous injections were given at five sites, the axillae, flanks and central back, and the volume of each injection was approximately 0.15 ml. Equivalent volumes of 3 per cent aqueous gelatine were administered to animals in control groups by each route. There was no loss of weight in any group during the 6 days after treatment.

After 6 days all mice were challenged with an intraperitoneal injection of a 10 per cent solution of washed sheep erythrocytes. Each animal was given 0.1 ml. containing approximately  $1.4 \times 10^8$  cells, and bled from the retro-orbital sinus 4, 6 and 10 days later. The group given the smaller dose of DMBA subcutaneously, and the subcutaneously injected gelatine control group, were also bled 75 days after challenge. Individual sera were titrated for haemagglutinins by the Takátsy microtitration method, and titres expressed as log<sub>2</sub> of the reciprocal of the last serum dilution which showed macroscopically visible agglutination. The results (Tables 1 and 2) indicate a marked depression in response in the subcutaneously injected animals at both doses, but insignificant decreases in the two groups treated orally. The mice are now 33 weeks old. Of the animals injected subcutaneously, those given the larger dose succumbed to generalized infection 2–3 weeks after carcinogen treatment. Three died during the experiment and the remainder had to be killed shortly afterwards because they were sick. At post-mortem all showed lymphoid involution. Early death was not indicated by the preliminary toxicity tests and it may be that the injection of sheep red cells in some way adversely affected recovery from a high dose of DMBA. There were no deaths among animals given the smaller dose of DMBA and each one of these twelve later developed subcutaneous tumours at one or more of the injection sites. None of the animals given DMBA orally has yet developed a tumour although it is likely that occult neoplasms are already present, or will later develop, in some of them<sup>7–15</sup>.

The reason for the difference in response between groups 3 and 4 and groups 6 and 7 is obvious. It is possible that the sensitivity of the system for the estimation of carcinogenic activity exceeds its sensitivity for the estimation

Table 2. STATISTICAL COMPARISON OF RESULTS SHOWN IN TABLE 1

of immunological impairment. Other work<sup>16</sup> has shown that subcutaneously injected doses of DMBA, smaller than those injected into each site in either of groups 3 or 4 of the present experiment, may induce sarcomas at the site of injection. Another possible explanation of the result is that only part of the orally administered DMBA was absorbed and, of that part, some may have been detoxified in the liver before it reached the reticulo-endothelial system.

Irrespective of the mechanism involved, the results of the experiment clearly show that large doses of DMBA, administered orally to mice, did not affect the haemagglutinin response to sheep erythrocytes, whereas smaller doses of the same agent injected subcutaneously caused marked depression.

## Respiratory Distress in a Newborn Foal with Failure to form Lung Lining Film

A SYNDROME in newborn thoroughbred foals, characterized by irregular respiration, convulsions, and lung pathology, has been described already<sup>1</sup>, and its resemblance to the respiratory distress syndrome of the newborn

human noted. This latter condition is associated with the absence of the surface active lung lining complex, or lung surfactant<sup>2</sup>; this absence can be investigated by observation of bubbles obtained from the lung<sup>3</sup>. From normal lungs bubbles of very low surface tension which show great stability in air-saturated water can be obtained<sup>4,5</sup>. The present case demonstrates the common factors operating in the two syndromes in the different species.

A thoroughbred foal was delivered at 336 days (average gestational length 340 days<sup>7</sup>). It was normal for about 32 h, after which it became unable to stand without support, and extensor spasms began. Breathing became shallow and rapid, the tidal volume falling from 700 to 320 ml., and the respiration rate rising from 25 to 85 per min, between 32 and 64 h after birth. The arterial oxygen pressure fell from 115 mm of mercury at 32 h to 74 mm of mercury at 57 h, while during the same period the carbon dioxide pressure fell from 53 mm of mercury to 30 mm of mercury. Meanwhile the neurological signs showed deterioration, and in spite of supportive measures including oxygen and intravenous bicarbonate the animal died after 78.5 h.

At autopsy pathological changes were confined to the lungs. These were wholly atelectatic except for small areas along the apical and cardiac borders; their consistency was that of liver. Histological examination showed widespread atelectasis with evidence of oedema, the persistence of cuboidal epithelium lining the alveoli and a general lack of normal alveolar patterns which should be established in the foal very rapidly after birth. There was no genuine hyaline membrane such as is seen in the infant.

The surface properties were compared with those of the lungs of normal still-born and live-born foals. Air injected into the specimen of affected lung caused local inflation, which subsided almost completely when the inflating pressure was removed; normal atelectatic lung shows a persistent white inflated patch. Bubbles squeezed from the partly aerated region into a hanging drop of air-saturated water usually contracted and dissolved; bubbles from the normal lung contracted a little and became stable. The behaviour of two typical bubbles is shown in Fig. 1. The ratio of final to initial surface area (stability ratio) of bubbles initially 30  $\mu$  to 50  $\mu$  in diameter was (means of batches of 30): from affected lung, 0.15, 0.09, 0.07; from normal lung, 0.72. The smallest bubbles from normal lungs (<1  $\mu$  diameter) showed Brownian motion; no such bubbles were obtained from affected lung. Larger bubbles (100  $\mu$  to 200  $\mu$  diameter) from normal lung, when dissolving in de-aerated water, showed the peculiar oscillations of shape known as "clicking"<sup>8</sup>; those from affected lung dissolved steadily. Extracts of both types of lung were formed by injecting saline and squeezing it out again, or by crushing a fragment in a drop of saline. Drops of the extracts were made to froth with the aid of

a hypodermic needle; the stability ratios of the bubbles formed were (means of batches of ten): affected lung, 0.0, 0.0, 0.0, 0.0; normal, 0.8, 0.8, 0.7, 0.5. These results demonstrate almost total absence of surfactant and failure to form a lining film. We think it very likely that, if the specimens had been tested by the trough method of Clements<sup>6</sup> used by Avery and Mead<sup>2</sup>, similar conclusions would have been reached.

The signs of rapid shallow breathing, lung atelectasis at autopsy, tendency of the lung to collapse after inflation, and absence of surfactant resemble those of the respiratory distress syndrome of the newborn human. The delayed onset in the foal suggests that some surfactant was present at birth but was used up more rapidly than it was produced. It is uncertain whether or not the onset of the human syndrome is ever delayed.

## GENETICS

### Effect of Blood Group on Blood Lipids in Monozygotic Twins

THE total variance of any measurement made in a population of monozygotic twins can be divided into two parts: interpair variance and intrapair variance. Calculation of the interpair/intrapair *F* ratio is informative because if this statistic is significantly large it shows that genotype affects the measured variable. Monozygotic twins of the same pair share a common genotype, and so intrapair variance is caused only by environmental effects. These can be divided into two parts: short term effects and long term effects.

A previous twin study of ours demonstrated significant interpair/intrapair variance ratios for total serum cholesterol, free cholesterol, total lipid phosphorus, and triglyceride in thirty-one pairs of monozygotic twins<sup>1</sup>. Blood for assay in our previous investigation was then obtained twice with a 48 h interval between bleedings. This study also demonstrated that certain twin pairs showed intrapair differences in total cholesterol, free cholesterol, and triglyceride of unexpected magnitude. Twins of blood group O appeared to have the largest intrapair differences of total and free cholesterol, particularly if they also possessed the secretor gene as judged by Lewis blood group typing<sup>2</sup>. We have now carried out a larger and more complete experiment on monozygotic twins to confirm or deny the existence of blood group effects on blood lipids and to examine short and long term environmental effects more fully. Ninety-five additional monozygotic twin pairs were bled three times a week on Monday, Wednesday and Friday. All twins were fasting, and all but a few were bled on the same day as their co-twins. Serum total cholesterol, free cholesterol, phospholipid, and triglyceride was determined by methods described before<sup>1</sup>. Determination of twin zygosity was based on blood typing for factors

Fig. 1. Time-course of behaviour of typical bubbles in hanging drop. Curve A, from affected lung; curve B, from normal lung, stability ratio of bubble 0.60.

A, B; Lea, Leb; Se, se; D, C, E, c, e; M, N, S, s; Fy<sup>a</sup>, Fy<sup>b</sup>; K, k; P<sub>1</sub>; and Vel by methods described before<sup>1</sup>. Analytical error in the determination of lipids, as shown by a series of blind replicate controls, did not differ in the two experiments.

To analyse short term variation in this experiment, we defined a variable  $S$  = standard deviation of the measurements of 3 days divided by the mean of these measurements (coefficient of variation). We obtained one value of  $S$  for each twin. To analyse long term variation we defined a variable  $D$  = log of absolute value of the difference between means of the two members of a twin pair divided by the standard deviation of the six values obtained from the pair (log  $t$ ). We obtained one value  $D$  for each pair of twins. The variance of these variables was analysed on a 4 (blood groups O, A, B, AB)  $\times$  2 (sex) model with age as a covariate. Only one  $F$  ratio (free cholesterol—blood group) was found to be significant at the 1 per cent level (Table 1). These results do not confirm the hypothesis that blood group affects intrapair differences between twins, but do clearly suggest that blood group affects the day to day change of free cholesterol. In the present experiment twins of blood group B showed more day to day variation in free cholesterol in both males and females than did members of any other blood group ( $P < 0.01$ ) (Table 2). In our previous twin experiment male twins of blood group B also showed greater day to day variation of free cholesterol, but the differences found between blood groups were not significant at the 1 per cent level.

Table 1.  $F$  RATIO TESTS,  $S$  AND  $D$  SCORES

Present experiment, 95 monozygotic twins, 3 determinations:					
Interpair $F$ ratio*	10.4	11.0	11.5	6.33	4.59
Intrapair variance					
Mean	0.130	0.091	0.096	0.098	0.071
Previous experiment, 28 monozygotic twins, 2 determinations (1):					
Interpair $F$ ratio†	3.39	5.01	5.81	6.07	4.35
Intrapair variance					
Mean	0.268	0.117	0.109	0.083	0.063

\* Degrees of freedom (94, 95).

† Degrees of freedom (27, 28).

Interpair/intrapair  $F$  ratios of this and of the previous twin experiment are shown in Table 3. All  $F$  ratios are significant at the 1 per cent level. The intrapair variance divided by mean is also shown for each lipid class in Table 3. Except for triglyceride, this statistic is not appreciably different in the two experiments. The smaller value for triglyceride intrapair variance/mean in the present experiment appears to be the result of increasing

the number of determinations from two in the previous experiment to three in the present one. Triglycerides are known to be the most variable class of lipid. It seems reasonable that this statistic, which is an estimate of long term variation for a set of twin pairs, should show the greatest refinement in the most variable class when more determinations are performed on each twin.

The results of this study contribute new information in two areas of interest: (a) the interrelation of blood group substances and other physiological substances, and (b) the inheritance of blood triglyceride level. Two previous reports suggest that blood group substances may be related to processes involved in lipid metabolism. Arfors, Beckman and Lundin have demonstrated a link between inheritance of blood group substance and a serum isoenzyme of alkaline phosphatase<sup>2</sup>. Inglis *et al.* have shown that this isoenzyme can be altered by ingestion of a fat meal<sup>3</sup>. In addition there is evidence that certain polysaccharides showing the activity of a blood group substance can activate lipoprotein lipase<sup>4</sup>. This report provides additional indication that blood group substances may be linked to processes involved in lipid metabolism. It suggests linkage to a function which controls synthesis and/or degradation of cholesterol before the time that cholesterol esters are formed.

Most current genetic studies of blood lipids are concerned with individuals with gross or abnormal concentrations in the blood. Familial likeness of serum total cholesterol has been demonstrated, however<sup>6,7</sup>, although total cholesterol is in the normal range. These workers studied each family member with a single determination of cholesterol. Familial likeness of normal serum triglyceride has been postulated but not proved to exist. The hypothesis that familial xanthomatous hypercholesterolaemia can be divided into two sub-groups—type II hyperlipoproteinaemia and type III hyperlipoproteinaemia<sup>8</sup>—is affected in several important ways by postulated familial likeness of normal as well as abnormal concentrations of triglyceride. Although studies of families with normal serum triglycerides do not exist, the  $F$  ratios and intrapair/mean ratios in Table 3 suggest that familial likeness of normal serum triglyceride can be of the same relative degree as that of normal serum total cholesterol. They also suggest that to determine likenesses of familial triglyceride it will be necessary to repeat several times the determination of this most variable lipid class in each family member.

## PHYSIOLOGY

## Minimum Heart Rates of Marsupials

STUDIES of the nutrition and nitrogen metabolism of some macropod marsupials (kangaroos and wallabies) suggested that the level of energy metabolism of marsupials may be lower than that of eutherian mammals<sup>1</sup>.

In the absence of facilities for direct study of the energy metabolism of marsupials, we have sought additional indirect evidence. One readily accessible measure is that of basal or minimum rate of heart beat, which in mature eutherian species has been shown to be related to metabolic body size ( $W_{kg}^{0.75}$ ), as is basal energy metabolism<sup>2,3</sup>. We have observed the minimum heart rates of fourteen species of marsupial.

The leads from an electrocardiograph were attached to the animals by small silver coated safety pins inserted subcutaneously in the chest region. The animals were fasted for at least 24 h and the kangaroos up to 48 h and the heart beat was monitored at intervals during this time. The koala bear was monitored for only 3 h after a light meal, and so it is unlikely that minimum heart rates were recorded. The smaller animals were placed in bags to limit their activity.

Table 1 lists the species used, their body weights and the minimum heart rate recorded. Only small numbers of animals could be tested because many species of marsupials are difficult to obtain. Some species are represented by only one animal.

Table 1. BODY WEIGHTS AND MINIMUM HEART BEAT RATES

Family	Binomen	Common name	Body weight (kg)	Minimum heart rate (beats/min)
Dasyuridae	<i>Antechinus flavipes</i>	Marsupial mouse	0.019	292
	<i>Phascogale tapoatafa</i>	Brush tailed phascogale	0.096	210
	<i>Myrmecobius fasciatus</i>	Numbat	0.36	102
	<i>Dasyurus geoffroyi</i>	Western native cat	0.80	89
	<i>Sarcophilus harrisi</i>	Tasmanian devil	(1) 4.26 (2) 5.93	54 66
Pera- melidae	<i>Isodon obesulus</i>	Short nosed bandicoot	1.31	84
Phalan- geridae	<i>Petaurus breviceps</i>	Sugar glider	(1) 0.112 (2) 0.119	183 312
	<i>Pseudocheirus occidentalis</i>	Ring-tail possum	0.695	102
	<i>Trichosurus vulpecula arnhemensis</i>	Kimberley brush-tail possum	0.950	99
	<i>Trichosurus vulpecula</i>	Brush-tail possum	(1) 1.36 (2) 1.51	62 98
	<i>Phascogale cinereus</i>	Koala	6.84	87
Macro- podidae	<i>Setonix brachyurus</i>	Quokka	(1) 2.72 (2) 2.38	119 121
	<i>Macropus eugenii</i>	Tammar	(1) 3.55 (2) 4.60 (3) 5.30	73 73 63
	<i>Petrogale lateralis</i>	Rock wallaby	5.45	86
	<i>Macropus robustus</i>	Euro or hill kangaroo	(1) 12.7 (2) 17.1 (3) 19.8	40 40 39
	<i>Macropus giganteus</i>	West Australian grey kangaroo	18.7	47
	<i>Macropus rufus</i>	Red kangaroo	19.8	40

The relationship between minimum heart rate and body weight (line B, Fig. 1) when plotted on a logarithmic grid was:

$$F = 106 W^{-0.27}$$

where  $F$  is the minimum heart beat rate and  $W$  is the body weight in kg.

This relationship is compared, in Fig. 1, with the relationship between heart beat rate and body weight for eutherian species given by Brody<sup>2</sup> of  $F = 217.8 W^{-0.27}$  (line A). The average minimum heart beat rate of the fourteen species of marsupials observed is a little less than half that given for eutherian species on the basis of metabolic body size.

Fig. 1. Relationship between minimum heart rate and body weight in marsupials (line B), compared with eutherian mammals (line A).

Bartholomew and Hudson<sup>4</sup> have reported a minimum heart rate of 300 beats/min for Tasmanian pigmy possums (*Cercartus nanus*) of about 50 g body weight, which correlates with the results presented here (line B).

The marked reduction in the heart rate of marsupials, compared with that of eutherians of similar body weight, suggests either a difference in metabolic activity or an equally marked difference between the haemodynamics of marsupials and eutherian mammals. Maxwell *et al.*<sup>5</sup> reported that the cardiac output of two macropod marsupials investigated under anaesthesia was similar to that of a dog when corrected for differences in body weight. The authors point out, however, that under anaesthesia the heart rates of the macropods were elevated when compared with the resting conscious state (no values given).

Handling and restraint can substantially increase the heart rate of an animal, but the use of an electrocardiograph over an extended period can minimize such effects. Brody's<sup>2</sup> curve is derived from data collected before electrocardiography came into widespread use; it is possible that line A may not be basal for eutherians.

Other parameters related to the level of energy metabolism are, however, lower, at least for some macropods studied. Brown and Main<sup>1</sup> have shown that the minimum output of urinary nitrogen of macropod marsupials is markedly less for each unit of metabolic body size than that of eutherian species, and that the voluntary feed intakes of these macropods were also less than those of ruminants. The water requirement and insensible water loss of the tammar wallaby (*Macropus eugenii*) are low in relation to those of eutherians (our unpublished results).

In the light of the available evidence, therefore, it seems probable that the low heart rates of the marsupials observed here imply a lower level of energy metabolism compared with that of most eutherian species.

We thank J. Kirsch of this laboratory and the West Australian Museum for making available several species, C. F. H. Jenkins of the National Parks Board for his co-operation in measuring the koala bear, and J. Firman of the Department of Physiology for the use of the electrocardiograph.

## Inhibition of Spinal Neurones by Glycine

THERE is now much evidence to support the role of glycine as a mammalian spinal inhibitory transmitter. The distribution of glycine in the spinal cord of the cat has been related to the presence of inhibitory interneurons<sup>1</sup>; glycine hyperpolarizes spinal motoneurons<sup>2</sup>; and strychnine, an antagonist of spinal postsynaptic inhibition, blocks the effects of glycine on spinal motoneurons, interneurons and Renshaw cells<sup>3</sup>.

There are considerable difficulties in determining whether the postsynaptic action of glycine is identical with that of the inhibitory transmitter, although both substances clearly hyperpolarize motoneurons. The measurement of "reversal" potentials by passing current through an intracellular micro-electrode may not necessarily establish the true relationship between the "equilibrium" potentials for ionic conductance increases which occur at sites unequally distributed over the cell membrane<sup>4</sup>. The reversal potential for inhibitory postsynaptic potentials (IPSP) of motoneurons<sup>5</sup>, however, has occasionally been almost identical with that of the hyperpolarization induced by the electrophoretic administration of glycine from the extracellularly located micropipette of a parallel electrode<sup>3</sup> (Fig. 1A). In other cases the reversal potential for the glycine effect was at a less hyperpolarized level than that of the IPSP, as might be expected if the ionic mechanisms were identical but the majority of inhibitory synapses were further from the site of intracellular polarization than membrane regions influenced by glycine. The finding that intracellular injections of anions (see also ref. 2), potassium or sodium ions influence both the IPSP and the glycine hyperpolarization in an identical fashion also suggests that these hyperpolarizations are produced by similar alterations in membrane conductance. It is noteworthy that  $\gamma$ -aminobutyric acid (GABA) apparently has the same postsynaptic action as glycine (Fig. 1B), although in general this amino-acid was a much less effective hyperpolarizing agent than glycine<sup>3</sup>.

Although it has been reported that glycine lacks effect on Renshaw cells<sup>2</sup>, it has been invariably found in this laboratory that glycine depresses the firing of these and other spinal interneurons<sup>3,6</sup>. Furthermore, this depression is reversibly blocked by strychnine, but that produced by GABA is not<sup>3</sup>. The firing of Renshaw cells can be inhibited by volleys in spinal and descending pathways and this inhibition is of the type which is sensitive to strychnine<sup>7</sup>.

Antagonism between strychnine and glycine has also been shown on spinal motoneurons, and an example is illustrated in Fig. 2. After administration of strychnine

Fig. 1. Potentials were recorded from a peroneal motoneurone (resting potential 65 mV) with one barrel of a double-barrel intracellular electrode ( $K_2SO_4$ ) while the membrane potential was altered by passing current through the other barrel. Amino-acids were ejected electrophoretically from separate barrels of an extracellular five-barrel micropipette (glycine, 50 n.amp; GABA, 125 n.amp). Ordinates, amplitude of an inhibitory postsynaptic potential evoked by stimulation of the flexor digitorum longus nerve, 2.5 mV at the resting potential. Abscissae, amplitude of the hyperpolarization produced by glycine (A) and GABA (B). Cat anaesthetized with pentobarbitone sodium.

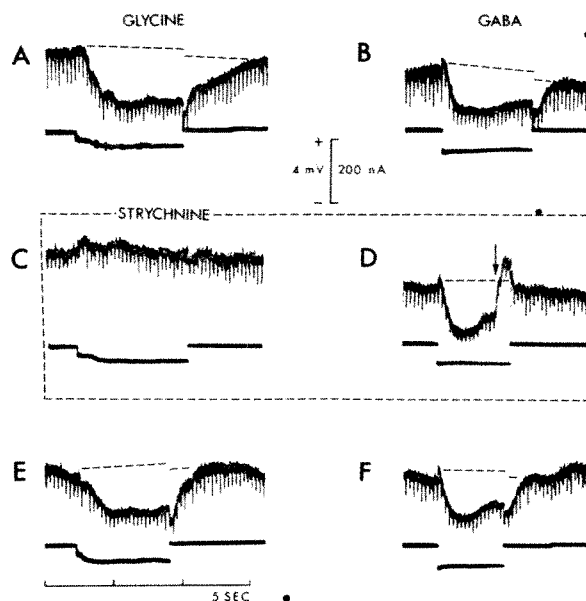

Fig. 2. Potentials recorded intracellularly from an anterior tibial motoneurone (resting potential 63-68 mV) in response to the extracellular electrophoretic administration of glycine (30 n.amp) and GABA (60 n.amp); the lower traces indicate the appropriate electrophoretic current. The brief downward deflexions are IPSPs evoked by stimulating the ipsilateral sural nerve. A, B, Control. C, D, During the electrophoretic ejection of strychnine from another barrel of the five-barrel extracellular micropipette (20 n.amp, 2 mmolar solution of strychnine hydrochloride in 165 mmolar NaCl). E, F, 4 min after the termination of the strychnine ejection. Calibrations, 4 mV for the intracellular recording, negativity down; 200 n.amp for amino-acid currents. Time, 5 sec.

for 7.5 min the hyperpolarizing effect of glycine was considerably reduced (C) whereas GABA (D) remained as effective as during the control period (B), apart from the late occurrence of a depolarization (arrow), the significance of which is being investigated further. Within 4 min of terminating the administration of strychnine, glycine again hyperpolarized the membrane (E). Strychnine reduced the IPSP studied in this cell by approximately 30 per cent, presumably because most of the activated synapses were not affected by the alkaloid, the distribution of which after electrophoretic administration would approximate that of glycine and GABA. Intravenously administered strychnine hydrochloride (0.1-0.2 mg/kg), which would influence inhibitory synapses in a more uniform manner, effectively reduced the glycine hyperpolarization of several other motoneurons.

Other substances like strychnine which reduce spinal postsynaptic inhibition<sup>8</sup> also diminish the depressant action of glycine, but not that of GABA, on spinal interneurons and Renshaw cells. These were administered electrophoretically and include bruceine, thebaine, 5,7-diphenyl-1,3-diazadamantan-6-ol, 4-phenyl-4-formyl-N-methylpiperidine and hexahydro-2'-methyl-spiro [cyclohexane-1,8'(6H)-oxazino(3,4-A)pyrazine].

The failure of strychnine to affect the action of GABA indicates that glycine and GABA apparently interact with different postsynaptic receptors, as was previously inferred from a study of the relationships between structure and activity of excitant and depressant amino-acids<sup>6</sup>. On the basis of strychnine antagonism, the depressant amino-acids can be separated into two types: "glycine-like" including glycine, L- $\alpha$ -alanine,  $\beta$ -amino-*iso*-butyric acid, D- and L-serine; and "GABA-like" including GABA,  $\delta$ -aminovaleric acid,  $\epsilon$ -aminocaproic acid,  $\gamma$ -amino- $\beta$ -hydroxybutyric acid and 3-aminopropane sulphonate.

If strychnine blocks the access of inhibitory transmitter to subsynaptic receptors, this pharmacological evidence strongly favours structural similarity between the transmitter and "glycine-like" amino-acids, of which glycine, L- $\alpha$ -alanine, taurine and L-serine are found in feline spinal tissue. On the other hand, if strychnine

merely reduces the potassium conductance at activated inhibitory synapses<sup>8</sup>, these amino-acids may not necessarily interact with the same receptor as the transmitter. The failure of strychnine to reduce the hyperpolarizing postsynaptic inhibition of certain supra-spinal neurones<sup>10</sup>, which presumably also involves an increased permeability to potassium ions, however, suggests that the interfering effect on spinal inhibition is most probably at the transmitter receptor site.

Glycine is rapidly metabolized in the spinal cord<sup>11</sup> and the distribution of incorporated glycine is remarkably similar to that of glycine as extracted by 5 per cent trichloroacetic acid<sup>12</sup>. Observations on the lack of action of a variety of enzyme inhibitors, including amino-oxoacetic acid, hydroxylamine, 2-hydroxy-ethyl-hydrazine, *p*-amino-hippuric acid and aminopterin on the glycine-induced depression of interneurons and Renshaw cells may indicate that glycine is effectively removed from the extraneuronal environment by rapid intracellular transfer, rather than by enzyme inactivation. This mechanism may be similar to the active accumulation of amino-acids by tumour cells<sup>13</sup> and brain slices<sup>14</sup>. It is perhaps significant that different membrane sites have been proposed for the transfer of "glycine-like" and "GABA-like" amino-acids into brain slices<sup>14</sup>. It is possible that the actual hyperpolarizing action of glycine is produced by intracellular transfer and the consequent re-distribution of potassium and chloride ions: such a mechanism is not incompatible with a function of glycine as a spinal inhibitory transmitter. If this glycine-induced ionic transfer was not solely restricted to inhibitory synapses which are sensitive to strychnine, this proposal provides an explanation of the finding that glycine depresses the firing of cortical neurones in the apparent absence of a post-synaptic inhibitory process affected by strychnine<sup>3</sup>.

## Acetylcholine, Strychnine and Spinal Inhibition

It was recently proposed<sup>1</sup> that the action of strychnine at spinal inhibitory synapses may be explained by an antagonism between strychnine and acetylcholine, an interaction between acetylcholine and presynaptically located receptors which are sensitive to strychnine being an essential requirement for the release of the inhibitory transmitter. This proposal, which would "eliminate blockade by strychnine as an essential qualification for the identification of a putative inhibitory transmitter" in the mammalian spinal cord, is based on the

finding that strychnine, in concentrations of the order of  $3-300 \times 10^{-6}$  molar, reduces the release of acetylcholine by impulses in the preganglionic terminals of the perfused feline superior cervical ganglion.

An opportunity has been taken to test this hypothesis on spinal neurones for which there is very good evidence that acetylcholine is an excitatory transmitter. The pharmacology of the excitation of Renshaw cells by impulses in motor axon collaterals bears some resemblance to that of cholinergic excitation in sympathetic ganglia<sup>2-4</sup>. Furthermore, Renshaw cells can be inhibited by appropriate spinal volleys<sup>5,6</sup>, and this inhibition is reduced by strychnine administered micro-electrophoretically<sup>7</sup>.

It has invariably been found that concentrations of strychnine, adequate to suppress the inhibition of lumbar Renshaw cells evoked by hind limb afferent volleys, enhance rather than reduce the excitation of these neurones by sub-maximal ventral root volleys. This facilitation might be explained as a blockade of a simultaneously occurring inhibition but, in view of the associated increase in the sensitivity of Renshaw cells to both acetylcholine and excitant amino-acids, a direct excitation of these cells by strychnine is a more likely explanation. Under conditions of comparatively high strychnine concentrations there is a reduction in the number of synaptically evoked spikes. This is, however, presumably indicative of a postsynaptic, rather than presynaptic, depressant action because it is accompanied by changes in the shape and size of action potentials recorded outside the cells and a diminution in the sensitivity of Renshaw cells to electrophoretically administered excitants<sup>7</sup>.

Thus no evidence has been obtained which would indicate that concentrations of strychnine sufficient to block the inhibition of Renshaw cells diminish the amount of acetylcholine released from axon collateral terminals. Unless it can be shown that there are differences in the susceptibility to strychnine of the acetylcholine-releasing mechanisms at the terminals of motor axon collaterals, the postsynaptic acetylcholine receptors on Renshaw cells and the proposed acetylcholine receptors on the terminals of inhibitory nerve fibres, the postulate that acetylcholine interaction with these latter receptors is necessary to initiate the release of inhibitory transmitter appears unnecessary. Furthermore, the recent demonstration that glycine hyperpolarizes spinal neurones, and that this effect is blocked by strychnine<sup>8</sup>, provides a more satisfactory explanation of the action of strychnine in terms of postsynaptic antagonism at inhibitory synapses.

## Pharmacological Characteristics and Ionic Bases of a Two Component Postsynaptic Inhibition

SEVERAL types of postsynaptic inhibition have been observed in molluscan neurones; in *Aplysia*, the most common is a rapidly decaying inhibitory postsynaptic potential (IPSP) with pharmacological characteristics which have been described by Taue and Gerschenfeld<sup>1</sup>.

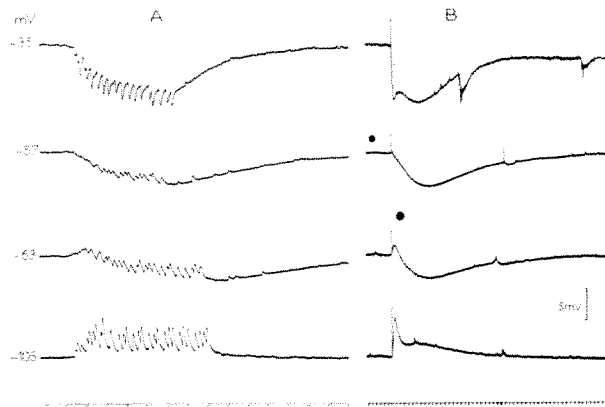

Fig. 1. Successive inversion of the first and second phases of the synaptic (A) and ACh (B) potentials with progressive hyperpolarization of the postsynaptic membrane. One barrel of a double-barrelled microelectrode filled with 0.5 molar potassium sulphate was used for intracellular recording; the other, for applying currents to displace the membrane potential to values indicated in mV. ACh ( $10^{-3}$  g/ml.) was injected ionophoretically on the cell soma by passing currents of approximately 300 namp during 400 msec. Time: second marker.

In their study of the role of acetylcholine (ACh) in the nervous system of *Aplysia*, they noted that cells receiving this inhibitory input are hyperpolarized by ionophoretic injection of ACh, and that both the ACh potential and the IPSP are blocked by *d*-tubocurarine. They also demonstrated that the polarization at which the ACh potential reverses is similar to that of the equilibrium potential for the IPSP, implying that the two potentials have the same underlying ionic mechanism. They concluded, on the basis of these and other data, that these IPSPs are cholinergic. Further work on similar cholinergic IPSPs in the land snail indicated that these potentials are the result of changes in the permeability of the postsynaptic membrane to chloride<sup>2</sup> with some possible contribution from potassium ions<sup>3</sup>.

I have observed in certain cells of *Aplysia californica* IPSPs similar to those described by Tauc and Gerschenfeld, but which are coupled with a more slowly decaying inhibition. The coexistence of two different types of postsynaptic inhibition in the same neurone has been described before<sup>4,5</sup>, but because the ionic and pharmacological characteristics of these inhibitory potentials were not thoroughly studied it is impossible to ascertain whether they are the same as those described here.

The dual component inhibition described here can be observed, using standard intracellular recording techniques, in an identifiable group of neurones in the pleural ganglia. This inhibitory input can be selectively activated when using the isolated-head preparation of Bruner and Tauc<sup>6</sup>. In a modification of this preparation, the head, which remains connected to the peri-oesophageal ring by the cerebral nerves, is isolated from these ganglia in such a manner that the tentacles can be stimulated mechanically without causing artefacts in the electrophysiological recording. Also, the solution bathing the ganglia is isolated from that (natural seawater) bathing the head, thus permitting changes in the ionic concentrations of, or addition of drugs to, the seawater bathing the ganglia without mechanically or chemically stimulating the head.

Drops of water falling on the tentacles produce within these pleural neurones a series of rapidly decaying IPSPs superimposed on a longer latency, more slowly decaying hyperpolarizing wave. A double-barrelled microelectrode was used to polarize the membrane progressively and to measure the inversion potentials of these two components. The earlier, short-decay potential was found to reverse between  $-55$  and  $-60$  mV; the later, long-decay potential, at approximately  $-80$  mV.

This dual-phased synaptic inhibition is particularly interesting because the cells receiving this inhibitory input

respond to ionophoretic injection of  $10^{-2}$  g/ml. of ACh with a similar two-component hyperpolarization. Fig. 1 shows that the two phases of this ACh potential show inversion potentials essentially identical to those of the first and second components, respectively, of the synaptic potential.

The disparity of the inversion potentials of the first and second component of both the ACh and synaptic potentials indicates that two different ionic mechanisms are involved. Changes in the concentration of potassium in the seawater bathing the ganglia markedly affect the inversion potential of the second component, and have no effect on that of the first. The inversion potential of the second phase ( $-80$  mV in normal seawater) is reduced to approximately  $-65$  mV when the external potassium concentration is doubled, and is increased to approximately  $-97$  mV when the potassium concentration is halved. The effects of an increase in the external potassium from 10 to 20 mmoles/l. can be seen in Fig. 2. Note that the inversion potential of the second phase is markedly reduced, whereas that of the first is left unchanged. Similar experiments in which the external chloride concentration has been varied indicate that the first component, on the other hand, is caused by an increase in the permeability of the membrane to chloride ions.

The synaptic and ACh potentials again demonstrate marked similarity in their response to the addition of *d*TC to the bathing solution. This substance readily blocks the first component of both the ACh and synaptic potentials, but fails—even at very high concentrations ( $10^{-3}$  g/ml.)—to block the second. This can be seen in Figs. 3 and 4, showing the effects of *d*TC  $10^{-3}$  g/ml. on the synaptic and ACh potentials, respectively. Note that whereas the first phase is completely blocked by the curare, the second phase is accentuated, showing a more abrupt decrease and a more prolonged action.

The first and second phase of the ACh potential cannot be explained on the basis of the selective activation of nicotinic and muscarinic receptors, respectively. Different cholinomimetics were injected on the cell soma, and the

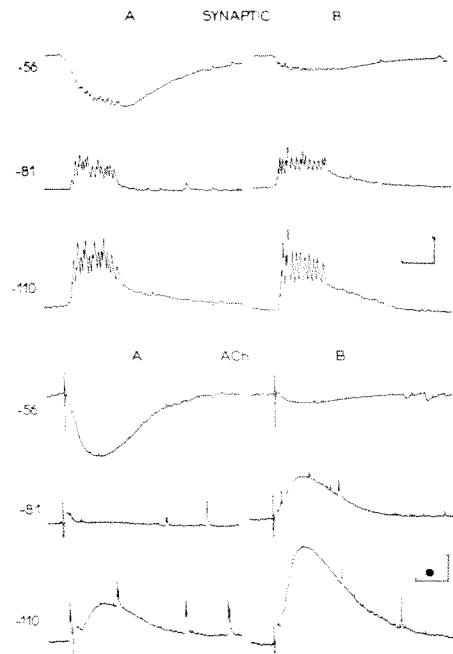

Fig. 2. Effects of doubling the external potassium concentration (10 mmoles/l. in A; 20 mmoles/l. in B) on the inversion potential of the second phase of the synaptic (upper half) and ACh (lower half) potentials. Note that the inversion potential of the second phase, which was  $-80$  mV in normal potassium concentration (A), was reduced to approximately  $-65$  mV when the external potassium was doubled (B). The inversion potential of the first phase remained unchanged. Calibration: synaptic potentials, 5 mV, 2 sec; ACh potentials, 5 mV, 10 sec. See Fig. 1 for description of recording and injection electrodes.

only agent—other than ACh—that was capable of producing a biphasic inhibitory potential was carbachol. All others—whether nicotinic (nicotine, propionyleholine, tetra-methyl-ammonium, and dimethyl-phenyl-piperazinium) or muscarinic (methacholine and oxotremorine)—mimicked only the early, rapidly decaying phase of the ACh inhibition. None of these substances provoked the longer latency, potassium dependent phase. Similarly it has not been possible to block either component of either the synaptic or ACh potentials with classical anti-muscarinic agents such as atropine or lachesine, even with concentrations as high as  $10^{-3}$  g/ml.

The possibility that the two components of the inhibition are caused by the action of two different transmitters cannot be excluded. An ionophoretic injection of dopamine on these cells causes a single phased, prolonged hyperpolarization, which—like the second phase of the ACh potential—reverses at  $-80$  mV. The existence in molluscan neurones of non-cholinergic potassium dependent inhibitory potentials has been established already<sup>7</sup>, and such data suggest the possibility that ACh causes the second phase indirectly by stimulating the release of another transmitter (for example, dopamine) from the presynaptic terminals. Such presynaptic action might also seem to be suggested by the long latency of the second component of the ACh potential. It seems that the ACh diffuses a considerable distance before reaching the receptor zone responsible for the second phase of the potential. Because the synaptic region of the neurones of *Aplysia* is located on the axon far from the soma<sup>8</sup>, however, diffusion to and selective activation of the sub-synaptic membrane could equally well account for such a delay. This interpretation is supported by the fact that both phases of the ACh potential persist in a calcium free solution ( $10^{-3}$  molar EGTA added) which presumably blocks transmitter release<sup>9</sup> and effectively blocks the synaptic input. These data suggest that the second phase as well as the first results from direct postsynaptic action of the injected ACh.

Two ACh receptor types seem to be necessary to account for the two successive states of membrane permeability. Neither of the two can readily be placed in classical pharmacological categories. The ACh receptors responsible for producing the second phase of the injection potential, whether pre- or post-synaptic, are of a particular interest because of their remarkable resistance to all standard blocking agents.

Fig. 3. Effects of dTC ( $10^{-3}$  g/ml.) on the two component ACh potential. Note that under curare (see AFTER) the first component is no longer visible, whereas the second component is accentuated. Calibration: 5 mV; time base, second marker. Recording and polarizing electrodes filled with 2.5 molar potassium chloride. See Fig. 1 for further specifications.

Fig. 4. Effects of dTC ( $10^{-3}$  g/ml.) on the two component synaptic inhibition. Note that under curare (see AFTER) the first component is no longer visible, whereas the second component is accentuated. Calibration: 5 mV; time base: second marker. Record taken simultaneously with that of Fig. 3.

### Evidence for Intracellular Transport of Radioactive Protein in Alveolar Cells

HISTOCHEMICAL studies have suggested that the acellular lining layer of pulmonary alveoli as well as the cytoplasmic inclusions (lamellar bodies) of alveolar cells contain carbohydrate-protein moieties<sup>1-3</sup>. These findings led me to investigate the subcellular site of incorporation of D-glucosamine-1-<sup>14</sup>C by alveolar cells induced by *M. bovis* (B.C.G.<sup>4</sup>). This designation does not imply that these cells are type II granular pneumocytes, but rather that they originate predominantly from cells that line normal alveoli<sup>5</sup>. The kinetics<sup>6</sup> of the subcellular distribution of radioactivity in cells which have been pulse labelled with glucosamine-1-<sup>14</sup>C suggest attachment of glucosamine to protein at the microsomal level followed by transfer of the labelled protein to particles which sediment at 15,000g. These data are consistent with the morphological studies of Sorokin<sup>7</sup>.

Twenty ml. of cells suspended in 5 volumes of Hanks solution (v/wet weight) were pulse labelled at 37° C with 25  $\mu$ Ci of D-glucosamine-1-<sup>14</sup>C, specific activity 10.9, for 40 min. The reaction was stopped by adding ice cold Hanks solution and the cells washed three times and resuspended in this medium. Equal volumes were then

reincubated for various times and the reactions stopped by chilling. The cells were collected by centrifugation and resuspended in 10 volumes (v/wet weight) of medium A (ref. 8). The cells were homogenized in a Potter-Elvehjem tissue grinder, a sample of the homogenate removed and the remainder centrifuged at 1,500g for 10 min. The supernatant fluid was centrifuged at 15,000g for 10 min and the sediment designated 15,000g fraction. The supernatant material was centrifuged at 105,000g for 1 h to sediment the microsomes. The remaining fluid was designated the supernatant fraction. The 15,000g and microsomal fractions were resuspended in medium A. Protein<sup>9</sup> and ribonucleic acid<sup>10</sup> were measured on all fractions. The samples were prepared for radioactivity assay and counted as previously described<sup>11</sup>.

Fig. 1 reveals the time course of the protein specific activity in the homogenate and various subcellular fractions. The specific activity of the homogenate indicates that net incorporation of radioactivity ceased after the first hour after the pulse. This time corresponds with the peak of microsomal protein specific activity. Thereafter, the protein specific activity in the microsomal fraction fell below that of the 15,000g fraction while the protein specific activity of the latter rose for 2 h after the pulse and remained above that of the microsomal fraction. These curves clearly fit a precursor-product relationship<sup>6</sup>. The protein specific activity in the supernatant fluid remained relatively constant throughout most of the experiment.

Table 1. PROTEIN-RNA RATIO OF SUBCELLULAR FRACTIONS

Incubation time (min)	15,000 g	Subcellular fraction Microsomes	Supernatant
0	0.04	0.23	0.02
30	0.05	0.20	0.04
60	0.08	0.21	0.02
120	0.06	0.19	0.03
180	0.07	0.18	0.02
240	0.05	0.19	0.03
300	0.04	0.13	0.04
360	0.06	0.10	0.04
Mean $\pm$ SD	0.05 $\pm$ 0.02	0.17 $\pm$ 0.03	0.03 $\pm$ 0.02

Table 1 shows the ratio of protein to RNA of each subcellular fraction. The ratio is about three times greater in the microsomal fraction than the 15,000g or supernatant fractions.

These data may be interpreted as incorporation of radioactivity into protein on the microsome followed by intracellular transport of the labelled protein to a particle which sediments when the cell homogenate is centrifuged at 15,000g; an alternative possibility is synthesis at more than one site but at different rates. This alternative would entail the unlikely possibility that synthesis by particles sedimenting at 15,000g increases at the same rate as microsomal synthesis falls, to maintain constant net synthesis in the cell as indicated by the constancy of protein specific activity in the cell homogenate. Further-

Fig. 1. Time course of protein specific activity in the homogenate (□), and in the 15,000g (●), microsomal (×) and supernatant (○) fractions.

more, in all systems studied so far carbohydrate incorporation into protein has been shown to be a microsomal function. Thus, all things considered, these data more strongly favour intracellular protein transport. This interpretation is consistent with the morphological data presented by Sorokin<sup>7</sup>.

These findings, which may be entirely unrelated to the biosynthesis of surfactant, as may the coincidental development of alveolar cell inclusions (lamellar bodies) and the appearance of surfactant in foetal lungs, assume potential significance when it is recalled that the 15,000g fraction probably contains many lamellar bodies<sup>12,13</sup>. Further, this fraction also has the greatest ability to lower surface tension<sup>12</sup>. Finally, when one considers that the enzymes required for the final stages of lecithin biosynthesis are microsomal enzymes, some type of intracellular transport is necessary for localization of surfactant in the 15,000g sediment<sup>14,15</sup>.

### Increase in Permeability of the Postsynaptic Membrane to Potassium produced by 'Nembutal'

'NEMBUTAL' (pentobarbital sodium) is known to block synaptic transmission, although its actual site of blockade is not well established<sup>1-5</sup>. On the other hand, the effect of 'Nembutal' and other barbiturates on the electrogenic membrane, which is capable of generating the conducted impulse, is generally considered to be less remarkable<sup>1,6</sup>. Neither the membrane resting potential nor the threshold firing level of cat motoneurons is significantly altered by barbiturates applied intravenously at a concentration of 10<sup>-3</sup> g/kg<sup>1,6</sup>.

Abdominal ganglion cells of *Aplysia* have been regarded as having little direct synaptic contact on their somata<sup>7</sup>, although the soma membrane is quite sensitive to acetylcholine, suggesting a structure analogous to the postsynaptic membrane<sup>8</sup>. When dilute 'Nembutal' (10<sup>-5</sup> g/ml.) is applied directly on the exposed ganglion cells by constant rate perfusion, the response induced by 10<sup>-6</sup> g/ml. of acetylcholine in both D- and H-type cells is readily blocked before the resting potential begins to be slightly hyperpolarized (1-3 mV). When concentrated 'Nembutal' of 10<sup>-3</sup> g/ml. is applied, both D- and H-type cells are equally hyperpolarized often as much as 20 mV during application, then gradually recover as 'Nembutal' is washed away (Fig. 3). Repetitive application of concentrated 'Nembutal' results in almost irreversible hyperpolarization. It is significant that the membrane resist-

Fig. 1. 'Nembutal'-induced hyperpolarization in perfusing media free of chloride ions. The cell is of a D-type which is depolarized by acetylcholine, as shown in top left. Repetitive downward shifts of the resting potential level are the monitoring of membrane resistance change in response to drugs. This was made by feeding a constant current pulse through one microelectrode inserted within a cell, and the potential drop across the membrane was recorded from another microelectrode inserted in the same cell. Pulse interval is 5 sec. Chloride ions were replaced by propionate in solution free of the ions. Top right is the control of 'Nembutal'-induced hyperpolarization in normal Ringer solution. Bottom trace is the same response in Ringer solution free of chloride ions. Acetylcholine and 'Nembutal' concentrations are 1 mg/ml. and 6 mg/ml., respectively. Horizontal bars on each trace indicate the extracellular potential levels.

ance markedly decreases during the 'Nembutal'-induced hyperpolarization, suggesting an increase in membrane permeability to certain ions. The observed hyperpolarization is unlikely to be produced simply by removal of excitatory background activities. If that were the case, the membrane resistance should increase during the hyperpolarization as the result of inactivated postsynaptic excitation.

The possible ions responsible for the observed hyperpolarization are chloride and potassium, because their equilibrium potentials are more negative than the resting potential<sup>3,8</sup>. If the 'Nembutal'-induced hyperpolarization were caused by an increase in the permeability of the membrane to chloride ions, the amplitude of hyperpolarization should be varied by changes in the extracellular concentration of these ions. It should be reversed into depolarization when all extracellular chloride ions are replaced by large impermeant anions. By contrast, the 'Nembutal'-induced response is not affected by the external concentration of chloride ions, as shown in Fig. 1. This excludes the possibility that chloride ions are responsible for the observed hyperpolarization. On the other hand, the 'Nembutal' response is greatly influenced by the external concentration of potassium ions. Some ganglion cells are not readily depolarized by a high external concentration of potassium ions because of intense inhibitory bombardment arriving at the cell as a result of the primary depolarizing effect of Ringer solution containing a high concentration of potassium ions on presynaptic fibres. Once treated with 'Nembutal', however, these cells are readily depolarized as much as would be expected from the Nernst equation. The destruction of inhibitory postsynaptic activities by 'Nembutal' is an important factor to explain the enhancement of the depolarization caused by potassium ions<sup>9</sup>. In addition, however, the augmented potassium ion depolarization may also be caused by the increase in permeability of the membrane to these ions produced by 'Nembutal'. When 'Nembutal' ( $6 \times 10^{-3}$  g/ml.) is applied simultaneously with a concentration of 220 mmoles/l. of potassium ions the usual hyperpolarizing response to 'Nembutal' is completely masked by enhanced potassium ion depolarization, as shown in Fig. 2. The increase in conductance during potassium ion

depolarization is greatly augmented with 'Nembutal'. When an adequate concentration of external potassium ions (50–60 mmoles/l.) is chosen, the usual 'Nembutal' hyperpolarization can be completely abolished despite the marked increase in membrane conductance. These observations strongly suggest that 'Nembutal' in a relatively high concentration actively increases the permeability of the postsynaptic membrane to potassium ions. The enhanced potassium ion depolarization gradually returns to a normal response to these ions as 'Nembutal' is washed away. The response to acetylcholine, which is completely blocked during the period of enhanced potassium ion depolarization, gradually recovers as the latter returns to normal. This parallelism suggests that the increase in permeability to potassium ions is maintained as long as 'Nembutal' occupies the acetylcholine receptors in the postsynaptic membrane. Fig. 3 shows the determination of the reversal potential of the 'Nembutal'-induced hyperpolarization. The reversal potential was found to be

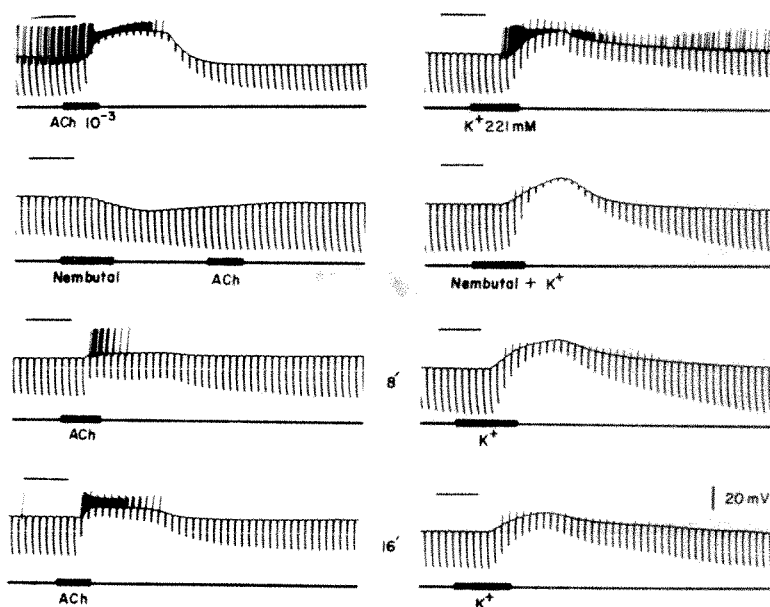

Fig. 2. Recovery of response to acetylcholine and the enhanced potassium ion depolarization of the same cell (D-type) after application of 'Nembutal'. Acetylcholine and 'Nembutal' concentrations are the same as shown in Fig. 1. Top traces are controls before 'Nembutal' is applied. The third and fourth rows were obtained 8 and 16 min after the second row. Note the marked decrease in membrane resistance during the potassium ion depolarization when 'Nembutal' was applied at the same time (right in the second row). Interval of resistance monitoring pulse is 5 sec.

Fig. 3. Determination of reversal potential of 'Nembutal'-induced hyperpolarization. The cell was of a D-type with a resting potential of 43 mV. The membrane potential was artificially shifted to various levels described in mV by passing inward or outward current through a micro-electrode during the recording of the response to 'Nembutal'. Concentrations are shown in g/ml. Interval of resistance monitoring pulse is 5 sec.

–72mV, which is approximately 10mV more negative than the chloride ion equilibrium potential<sup>8</sup> but corresponds with the potassium ion equilibrium potential calculated from the intracellular concentration of potassium ions

$$E_K = -\frac{RT}{F} \log_e \frac{[K^+]_i}{[K^+]_o} = -56 \log_{10} \frac{232}{11.6} = -72 \text{ mV}$$

where  $[K^+]_i$  and  $[K^+]_o$  are the intracellular and extracellular concentrations of potassium ions, respectively. The former was measured by an atomic energy absorption spectrophotometer and the mean value of 400 cells was 232 mmoles/l. The latter is the concentration of potassium ions of our artificial *Aplysia* Ringer solution, 11.6 mmoles/l. The temperature of the preparation was kept constant at 10° C.

We conclude from the above findings that 'Nembutal' combines with acetylcholine receptors in the postsynaptic membrane and causes a specific permeability increase to potassium ions when the concentration of 'Nembutal' is sufficiently high. As described here, however, the responses of D- and H-type membranes to acetylcholine are blocked by more dilute 'Nembutal' which does not appreciably affect the permeability of their membranes to potassium ions. Apart from this dose dependence on the blocking action of 'Nembutal' on synaptic transmission, it is interesting that this compound has a molecular affinity for the receptors in the postsynaptic membrane and that its binding can cause a specific permeability increase toward a certain ion in a manner similar to the action of transmitter substance. The molecular basis to account for this ionic specificity awaits further investigation.

### Sequence Theories of Blood Coagulation re-evaluated with reference to Lipid-Protein Interactions

THE well-known "sequence" theories of blood coagulation<sup>1,2</sup> attempt to rationalize the participation of a dozen or so clotting factors in the formation and consolidation of a fibrin clot. It has been proposed<sup>3</sup> that "normal" prothrombin activation involves a number of functionally and perhaps physically distinct entities (clotting factors) present in the plasma, that these react one upon the other in a preferential sequence during normal clotting and that most, if not all, are proenzymes each yielding an enzyme capable of activating the next component of the sequence". Several investigations have been concerned with the last of these propositions<sup>4-11</sup>. Each of these has involved the assumption that a linear response in reaction velocity with changing concentration is indicative of an enzyme while a saturation response is indicative of a substrate. The validity of these assumptions and their consequences will now be considered.

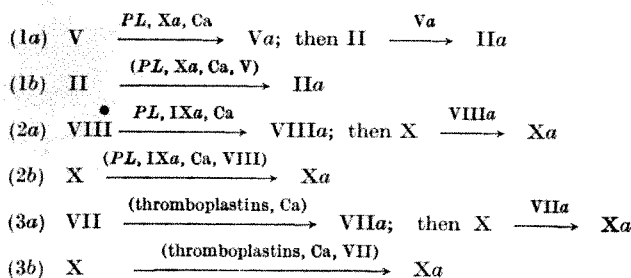

The steps necessary to establish an enzyme-substrate relationship are as follows. (a) To construct a reasonable model for the interactions of known participants. (b) To predict the kinetic behaviour of the proposed model. (c) To show that the kinetic behaviour of the real system is consistent with that predicted for the model.

This argument is based on inductive reasoning as opposed to deductive reasoning. Assuming that (c) is satisfied, this does not constitute proof of the reality of the model but merely indicates that the model is feasible. Kinetic analysis of a reaction mechanism is therefore of value only where a reasonable model can first be proposed. For each of the following reactions involving clotting factors we shall have to consider whether the application of the general Michaelis-Menten treatment can be justified. The reactions are: the interaction of plasma factors V, Xa, phospholipids and calcium ions; the interaction of factors VIII, IXa, phospholipids and calcium ions; the interaction of factor VII, tissue thromboplastins and calcium ions.

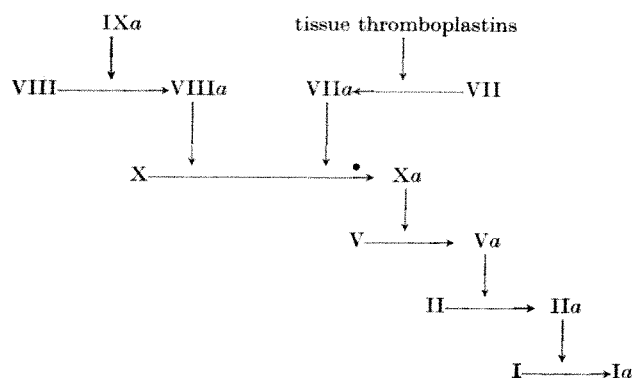

In each of these reactions the various components apparently combine to form a macromolecular complex which possesses the activity necessary to initiate a subsequent reaction<sup>12-15</sup>. Phospholipids in aqueous dispersion exist in the form of aggregates in which the charged groups are arranged at the lipid-water interface. It has been suggested therefore that phospholipids participate in blood coagulation by providing a catalytic surface for the interactions of the protein clotting factors<sup>16-18</sup>. The participation of a biphasic system (heterogeneous catalysis) introduces additional rate components related to diffusion constants of the reactants and products and to their adsorption and desorption isotherms. Depending on the adsorption characteristics of the particular proteins involved it may well be possible to seem to demonstrate an "enzyme-substrate" relationship where one does not in fact exist<sup>19</sup>. Consequently, the kinetics of such reactions would not be amenable to interpretation on the basis of a classical Michaelis-Menten model. In this light the sequence designations of the clotting factors, based on such interpretations, must also be suspect.

We have therefore to consider alternative experimental approaches to test the "cascade-waterfall" hypothesis.

In each of reactions 1-3 two models are possible; (a) involves the formation of an entirely new intermediate (Va, VIIIa, VIIa) while (b) is catalysed by a lipoprotein complex.

If model (a) is applicable in every case, the partial sequence must be

whereas if model (b) is applicable in every case the partial sequence would be

(V, VII, VIII and X are plasma factors; a represents an activated form. I is fibrinogen, Ia is fibrin, II is prothrombin, and IIa is thrombin.) It is not, of course, necessary to assume a uniform model for all three reactions, but because of their superficial similarity<sup>13</sup> it is tempting to do so. The crucial experiment in each case is to determine whether or not a distinctly new entity (Va; VIIIa; VIIa) is formed which can be separated from the other reactants and which can then participate with other materials in the subsequent interaction in the sequence. In the first example selected (reaction 1) no activated factor V is formed, but the reaction with factor Xa, phospholipids and calcium ions is reversible and factor V can be recovered apparently unchanged<sup>20, 21</sup>. Furthermore, there is direct evidence that activated factor X alone will convert prothrombin to thrombin in a reaction which can then be accelerated by the addition of factor V, phospholipids and calcium ions<sup>20-22</sup>. Thus, for reaction 1 there is compelling evidence for model (b) which is in direct conflict with the conclusion inferred from kinetic measurements<sup>8, 9</sup>. Concerning reaction 2, the existence of

a lipoprotein complex (VIII, IXa, phospholipids, Ca) capable of activating factor X has been demonstrated by the gel filtration technique<sup>13</sup>. We have now found that when the complex is rechromatographed on 'Sephadex G-200' in the absence of calcium, factors VIII and IXa can be recovered unchanged and that no component can be eluted from the columns which will activate factor X without first adding back the complementary factors. Experimental details of this work will be published elsewhere. Thus there is again strong evidence that significant activity resides only in the intact complex. With regard to reaction 3 the existence of a thromboplastin-factor VII complex is well documented, but attempts to demonstrate the hypothetical VIIa free from the lipoprotein complex have been inconclusive<sup>14, 15</sup>. Treatment of the complex with a variety of reagents designed to disrupt different types of intramolecular bonds either failed to dissociate the complex or resulted in a loss of activity.

In summary, it seems evident that the evaluation of the kinetic data concerned with these reactions has been based on the preconceived assumption that the "cascade-waterfall" hypothesis is correct. The sequences with regard to factors V and Xa, factors VIII and IXa and factor VII and the tissue thromboplastins therefore still remain to be firmly established.

### Transformation of the Histochemical Profile of Skeletal Muscle by "Foreign" Innervation

EVIDENCE that long term neuronal influence has a decisive role in determining the cytochemical features of skeletal muscle cells is presented in this report.

The soleus muscle of the adult guinea-pig is histochemically completely "uniform", containing only type I extrafusal muscle fibres. Type I fibres display low activity of myofibrillar ATPase, menadione-mediated  $\alpha$ -glycero-phosphate dehydrogenase and amylophosphorylase, and high activity of most dehydrogenases and EDTA activated myofibrillar ATPase<sup>1</sup>. (In type II fibres, the relation of the activities of these enzymes is reversed.) All other limb muscles examined in the guinea-pig are histochemically "mixed", containing type I and type II fibres. The histochemically "uniform" character of the

adult soleus makes it an excellent subject for the present experiments, for even a few "transformed" muscle fibres can be readily discerned.

Male albino guinea-pigs 3 months of age were used. "Foreign innervation" was produced on one side of each animal by one of three methods; the other side of the animal served as a control. The three methods are: (a) implanting the common peroneal nerve, which normally innervates mixed muscles, to the denervated soleus (12 animals); (b) complete section, rotation and re-suture of the sciatic or posterior tibial nerve (6 animals); (c) vigorous, multiple crush of the sciatic or posterior tibial nerve (6 animals). It was thus planned that at least some nerve fibres which normally innervate histochemically "mixed" muscles would regenerate into the soleus and innervate some of its muscle fibres. In six control animals, self re-innervation of the soleus was produced by vigorous crush of its small nerve. The experimental and control animals were killed at four and six months (a few at two months) after treatment. The muscles were examined by preparing serial cryostat sections<sup>2</sup>, 10 $\mu$  thick, of the entire cross section of the muscle at its mid-point. A series of histochemical tests was applied to the fresh, frozen sections, as described elsewhere<sup>1</sup>.

All experimental and control solei become virtually completely re-innervated, as shown by the normal size and architecture of nearly all the muscle fibres and the normal excitability of the muscle through the nerve.

In all experimental soleus muscles, a number of typical type II fibres were present in small and large groups and were best displayed with the myofibrillar ATPase reaction which is our preferred method for identifying histochemical fibre types<sup>3</sup> (Fig. 2). In the experimental groups (a) and (b), the amount of type II fibres was estimated to be 5-40 per cent of the total cross-sectional area in the muscles of different animals. In animals of group (c), they were only 1-3 per cent of the area. Variation in the quantity of type II fibres appearing in the experimental solei is probably attributable to technical factors. In the solei on the control side of experimental animals and in the self re-innervated solei, no type II fibres were seen (Fig. 1). It appears that a portion of the original type I fibres of the soleus was "transformed" into type II fibres as a result of innervation by "foreign" nerve fibres. It is suggested that the ability to transform muscle fibres is a feature of the trophic function of the motor nerve. The present experiments confirm the findings of Romanul and Van der Muelen<sup>4</sup>, who demonstrated the appearance of type II fibres (though not using the myofibrillar ATPase reaction), in "cross innervated" solei of cats and rats. Results of self re-innervation were not reported by these authors.

Fig. 1. Entire cross section of a self-innervated soleus muscle, 6 months after treatment. Myofibrillar ATPase reaction,  $\times c. 10$ . Only light, type I fibres are present, as in unoperated control adult soleus muscles.

Fig. 2. Entire cross section of a soleus muscle, 6 months after "foreign" innervation. Myofibrillar ATPase reaction,  $\times c. 10$ . Numerous dark, type II fibres are present and occupy about 40 per cent of total cross-sectional area.

It has been reported that in cats<sup>5,6</sup> and rats<sup>7</sup>, the speed of the slow soleus is increased when it is innervated by a nerve normally supplying a fast muscle. A direct relationship of this physiological change to the appearance of type II fibres in foreign innervated solei has not yet been demonstrated, although the two changes are concurrent. One possible method of determining a direct relationship, if it exists, would be the demonstration of a quantitative correlation between the amount of type II fibres (as percentage of cross-sectional area), and the changes in the various physiological parameters within each foreign innervated muscle.

### Interactions of DDT with the Nervous System of the Resistant and Susceptible German Cockroaches

DDT is regarded as a nerve poison in insects and mammals chiefly from the symptomological, electrophysiological and biochemical points of view<sup>1,2</sup>. The actual mechanism of DDT poisoning at the target, however, is not known.

Recently a hypothesis was proposed to explain the mode of action of DDT on the basis of charge-transfer complex formation of nerve components with DDT<sup>3</sup>. The first obvious step toward providing evidence for this hypothesis is to confirm the formation of a DDT complex with nerve components through physical separation of the complex. Matsumura and O'Brien were able to do so by showing that DDT was quickly adsorbed by the intact nerve cord and the various nerve components of the homogenates of the American cockroach<sup>4</sup>. They also found that this binding process was accompanied by the shift in the ultra-violet absorption spectrum<sup>5</sup>. These results alone, however, may not be sufficient to prove or disprove the hypothesis, for it cannot provide evidence that such complex formation is causally related to the actual process of DDT poisoning. That is, DDT is a very apolar compound, and it is only

Fig. 1. 'Sephadex' column elution of DDT complexes from the resistant and susceptible homogenates which had been incubated with free  $^{14}\text{C}$  DDT.  $\circ$  ---  $\circ$ , VPI;  $\circ$  - - -  $\circ$ , VPI-DDTR;  $\times$  - - -  $\times$ , London;  $\bullet$  -  $\bullet$ , CSMA.

natural that it is either absorbed or bound to lipid containing neural substances such as lipoproteins in an aqueous system. To prove that such a binding phenomenon is genuinely related to the process of poisoning, it is necessary to find a specific system, in which the increase or decrease in the amount of DDT binding to a particular nerve component causes a marked change in the susceptibility of the test organisms. Such an example may be found in the insect colonies resistant to DDT, provided that the mechanism of resistance in those insects is not simply related to an increased elimination system of the toxicant before it reaches the target site.

The strains used to test this possibility were the CSMA susceptible and the Fort Rucker strain (both  $LC_{50}$  at 0.0032 per cent, as determined by a dipping method<sup>6</sup>), and the London ( $LC_{50}$  at 0.06 per cent) and the VPI strain ( $LC_{50}$  over 2 per cent) respectively. Preliminary experiments first established that the London strain had an identical rate of degradation and excretion of DDT as compared with the CSMA strain. The head parts from the male cockroaches were collected and homogenized in 0.25 molar sucrose solution at a concentration of three heads/ml. by using a small 'Teflon' Potter-Elvehjem homogenizer at 0°C. The weight of the head samples from each

Fig. 2. 'Sephadex' column elution of DDT complexes from the VPI DDT-resistant and CSMA susceptible supernatant which had been incubated with  $^{14}\text{C}$  DDT.  $\circ$  ---  $\circ$ , VPI;  $\bullet$  -  $\bullet$ , CSMA.

strain was carefully measured to ascertain the equality of the homogenate concentration among the strains.

A binding experiment similar to those of previously reported dieldrin cases<sup>7</sup> was then conducted with the head homogenates. The results, given in Table 1, indicated that the DDT molecule indeed bound with various subcellular components of the roach head; that the resistant crude nucleus fractions had less binding capacity than did the susceptible counterparts; and that the resistant supernatants contained more DDT.

Table 1. ABSORPTION OF  $^{14}\text{C}$  DDT TO VARIOUS SUBCELLULAR COMPONENTS

Fractions	VPI	Strains		
		London	Ft. Rucker	CSMA
Crude nucleus	66.4	65.8	72.7	71.2
Mitochondria	6.3	6.8	4.7	8.3
Microsome	4.9	4.6	2.8	5.3
Supernatant	22.4	21.8	19.9	14.9

Absorption data are expressed in percentage of DDT added.

The supernatant fraction may still contain unknown amounts of free DDT and therefore the fraction from each strain was analysed chromatographically with 'Sephadex G-50' gels as before<sup>7</sup>. The resulting chromatograms indicated that under the conditions tested—that is 7.5 mg/ml. of homogenate concentration—no elutable free DDT existed. Nor was there any DDT that was bound to true soluble proteins. Instead all DDT was found to be associated with very small particles (or with the gel particles), and it could only be eluted by denaturing the 'Sephadex' gel with 95 per cent ethanol. Only when the homogenate concentration was increased to 100 mg/ml. was a portion of administered  $^{14}\text{C}$  DDT eluted with soluble proteins (Fig. 1). It was also found that the binding capacities of the resistant supernatants were considerably higher than those of the susceptible strains. The difference was not caused by the presence of other subcellular fraction in the homogenate, because an experiment with the supernatant alone showed a similar result (Fig. 2).

Fig. 3. Ultra-violet absorption spectra of DDT and DDT administered cockroach brain homogenates. —, DDT; . . . , VPI; - - - , London; - - - - , Fort Rucker; —, CSMA.

To investigate further the nature of DDT binding in relation to the formation of possible charge-transfer complexes with the roaches' nerve components, ultra-violet spectra of these DDT-complexes were then studied. Fig. 3 illustrates the change in the ultra-violet spectra<sup>8</sup> of DDT in an aqueous condition on reaction with the brain homogenate (exclusive of large particles which sediment at 600g). It can be seen that in all cases the shape, the positions and the heights of the main peaks shifted, and that the degree of shifting was highest with the S-homogenate and the lowest with the VPI-homogenate. To ascertain that this large shift in the susceptible homogenate is caused by the fine subcellular particles in the homogenate, it was centrifuged for 4 h at 140,000g with 0.06 molar sodium phosphate buffer to eliminate all particles. The resulting supernatant was treated with

Fig. 4. Ultra-violet absorption spectra of DDT and DDT administered cockroach brain supernatants. —, DDT; ·····, VPI; ---, London; - · - · -, Fort Rucker; ———, CSMA.

DDT as before. Fig. 4 indicates similar shifts in the ultra-violet spectra of DDT aqueous suspensions on addition of various supernatants. The principal difference here is that the order of binding was the complete reverse of the previously observed data with homogenates.

The results described here indicate that the resistant particulate components indeed have less binding capacity with DDT than do the susceptible components. This finding is in agreement with the previously predicted view that there should be a binding difference between the strains at a specific binding site which is related to the susceptibility of the test organisms, if such a site is actively engaged in the process of attaining a high level of DDT resistance by the roaches. Despite this additional piece of evidence in favour of the hypothesis, there are a number of problems remaining unsolved. One is the lack of information on the identity of this particulate component(s) which causes the interstrain difference, and another is the absence of genetical study on the above roach strains. Unfortunately the amount of the binding substances present in the nerve preparation was too small to permit any chemical analysis, and the relatively long life span of the German cockroach does not permit the genetic cleaning experiments<sup>9</sup> required to eliminate strain differences due to geographical variations at this time. In conclusion, we have found that DDT does indeed bind with various components of the German roach nerve, and that the particulate nerve components from the cockroaches resistant to DDT have less binding capacity with DDT than do the susceptible components, implying that these resistant cockroaches could be utilizing this vital process for their advantage. Whether this binding substance can play an indispensable part in DDT poisoning is, however, a problem requiring further study.

This work was supported by a US Public Health Service research grant from the National Communicable Disease Center, Atlanta, Georgia. We thank WHO for supplying <sup>14</sup>C DDT.

## Effect of Cold on the Vitamin E Requirement of Rats

SINGH<sup>1</sup> has suggested that man's vitamin E requirement increases at high altitudes. Vitamin E is known to be involved in the transport of oxygen in the respiratory chain, and it could facilitate oxygen transport during enzyme adaptation to hypoxia. At an altitude of 3,450 m and a temperature of 20° C, rats have shown neither an increased requirement for vitamin E nor an improved fitness when given vitamin E<sup>2,3</sup>. These negative results were found at constant conditions of ambient temperature at which the oxygen consumption at a high altitude is known to be low<sup>2</sup>. The turnover of vitamin E would be expected to increase with any increase in oxygen consumption, and because temperature decreases with altitude and oxygen consumption increases with decreasing temperature, the greater requirement for vitamin E postulated by Singh<sup>1</sup> could be caused by exposure to cold and not by hypoxia at a high altitude. We have investigated the vitamin E requirement of rats at high and low temperatures independent of altitude.

Female Wistar rats of the conventional breeding colony Füllisdorf, 4 weeks old at the onset of the experiment, were used. They were given freely a diet containing no vitamin E<sup>4</sup>. Animals were kept at room temperature (28° C) in wire cages, four to a cage. Vitamin E depletion was determined by haemolysis induced by dialuric acid, by the method of Friedman *et al.*<sup>5</sup>. As soon as the blood had reached 95 per cent haemolysis in all animals, each received daily, for 15 consecutive days (without weekends), 1 ml. of *dl*- $\alpha$ -tocopherol acetate dissolved in 0.2 ml. of peroxide and vitamin E-free olive oil. With this treatment the haemolysis values returned to zero, which indicated an adequate provision of vitamin E. The animals were then divided randomly into two groups of twelve; one group was transferred to a cold room at 1° C while the other group remained at 28° C. In both groups the progressive depletion of vitamin E was determined at regular intervals by the increase in percentage haemolysis. Food consumption was calculated from the total food consumed by each group during the experimental period.

		Table 1			
		1° C		28° C	
Days after application of vitamin E	N	Mean haemolysis (per cent)	N	Mean haemolysis (per cent)	
0	12	0	12	0	
8	12	7.2	12	10.5	
17	12	23.4	12	21.9	
22	12	38.2	12	25.3	
30	12	51.5	12	41.0	
38	12	88.1	12	81.2	
45	12	92.7	12	82.4	
g of food/animal/day		17.6		15.5	

The mean values of haemolysis for both groups showed a steady depletion of vitamin E (Table 1). The linear regression was computed by the maximum likelihood method for probit lines. This was  $y = 3.2061x + 0.3892$  for the cold group and  $y = 3.8794x - 0.3333$  for the warm group. The exact end-point of the experiment was determined by the crossing point of the regression line with the probit line of 6.64 (95 per cent haemolysis) and was found to be 62.7 days for the cold and 95.4 days for the warm group. The mean daily vitamin E consumption by an animal of the cold group was 0.24 mg and by the warm group 0.16 mg. The daily food consumption by each rat during the experimental period was 17.6 g in the cold and 15.5 g in the warm group, the increase after exposure to cold being 13.5 per cent.

The results of the investigation show that in the experimental conditions the vitamin E requirement of the rats in the cold was 50 per cent greater than in the warm. We do not believe that this is an absolute figure. In this experiment, rats were housed in groups of four, which

enabled them to protect themselves from extreme heat loss by huddling together. According to the findings of Cottle and Carlson<sup>6</sup> with individually housed rats, the production of heat by the animals and later their intake of energy should have increased by more than 100 per cent. We saw a moderate increase of only 13.5 per cent with exposure to cold and believe that this low figure is an expression of a protection from severe heat loss brought about by the behaviour of the animals. If protection from heat loss is avoided and animals become fully exposed to the cold, higher daily requirements of vitamin E must be anticipated.

These results suggest that if an increased vitamin E requirement exists at high altitudes, it is more likely to be caused by the cold exposure than by hypoxia. There is no information about the vitamin E requirement of man in a cold environment<sup>7</sup>. There is evidence that vitamin E depletion is caused by exposure to cold when no supplementary vitamin is given in the frequent and sudden occurrence of muscular dystrophy among calves and lambs during the cold season<sup>8-11</sup>. It is not certain, however, that this form of dystrophy is entirely caused by vitamin E deficiency.

## BIOLOGY

### Production of Plant Growth Inhibitors from Xanthophylls: a Possible Source of Dormin

THE plant growth inhibitor, dormin, shows similarities in structure to certain carotenoids and, because there is evidence that light stimulates the production of inhibitor  $\beta$  (refs. 1 and 2), the principal activity of which is probably caused by dormin<sup>3,4</sup>, we have studied the possible formation of inhibitory substances by illumination of these pigments.

Carotenoids, extracted from dried nettle (*Urtica dioica* L.) leaves<sup>5</sup>, were stored in the dark under vacuum. Samples (50 mg) were dissolved in peroxide-free ether (100 ml.), washed with 2 per cent aqueous sodium bicarbonate to remove endogenous inhibitors and then with water. Samples (2 ml.) of the ether solution were added to disks of Whatman No. 1 filter paper in 5 cm Petri dishes, and the solvent allowed to evaporate. All these processes were carried out in weak green light. The open Petri dishes were then kept in the dark or illuminated 30 cm from a 500 W tungsten lamp for 3 h. The light was filtered through water (5 cm path) and a stream of air at about 25° C was directed over the dishes. The paper in each dish was then moistened with water (1 ml.) and

twenty cress seeds (*Lepidium sativum* L.) were placed on it. The dishes were closed and transferred to a darkened humidity box at 23.5° C. After 60 h the germination of the seeds on the illuminated filter papers was negligible compared with that on the papers which had not been exposed to light. The mixed carotenoids (100  $\mu$ g) irradiated in this way gave an inhibition comparable with that shown by synthetic ( $\pm$ )-dormin (1  $\mu$ g).

Heating the pigment-treated papers in the dark for 3 h at 55° C did not reproduce the light treatment, although higher temperatures were partially effective. The inhibition was less when the pigments were illuminated over phosphorus pentoxide or alkaline pyrogallol solution, which suggests that water and oxygen are necessary in this conversion. The inhibitor eluted from filter paper with ether was shown to partition in the non-acid fraction and may be an alcohol or aldehyde, perhaps being converted to a carboxylic acid, like dormin, within the cress seeds.

Fig. 1. Structures of violaxanthin and dormin.

The carotenes, which had been shown to be inert, were removed by partitioning between petroleum ether and 90 per cent aqueous methanol. The lower methanol layer was then diluted with water, and ether extracted to recover the xanthophylls. Thin-layer chromatography in the dark on silica gel *G* using benzene: ethyl acetate (3:1) as solvent, separated at least five pigments. The bands of silica gel were immediately eluted with ether to minimize the oxidation which occurs on the dry adsorbent. On illumination, these eluted pigments did not produce inhibition in proportion to the intensity of their initial yellow colours, but the greatest inhibitory effect was obtained with one of the minor xanthophylls present in the nettle leaf extract. This has been tentatively identified as violaxanthin.

These findings may explain many of the responses to blue light which are reported to occur in plants; in particular, phototropism in *Avena coleoptiles*<sup>6</sup> in which tissue violaxanthin has already been shown to be the principal carotenoid<sup>7</sup>. It is also known that blue light inhibits root elongation<sup>8,9</sup> and seed germination<sup>10,11</sup> in certain plants. Moreover, the production of dormin in deciduous leaves may be related to the exposure of the xanthophylls to light in the autumn, a time when the chlorophyll is lost.

It is thus possible that the photo-oxidation of certain xanthophylls is a mechanism by which growth inhibitors are produced in plants. Because more than one xanthophyll gave rise to inhibition, more than one dormin-like inhibitor may be produced in this way.

We thank Dr S. T. C. Wright for the discussion which initiated this study and Professor R. L. Wain for his

advice and encouragement. We also thank Dr J. W. Cornforth for a sample of synthetic dormin.

### Effect of Benzyl Adenine on Isolated Apple Shoots

EVIDENCE for export from roots to shoots by way of the xylem of substances with biological activity similar to that of kinetin has accumulated in recent years. The significance of these substances in relation to shoot growth is, however, not fully understood. Evidence suggests that cytokinins from roots have beneficial effects on the protein and chlorophyll of leaves<sup>1-4</sup>, and results obtained with vine cuttings show that the effects of roots on inflorescence retention are simulated by supplies of synthetic cytokinins<sup>5</sup>.

The possibility that apple roots supply cytokinins to the shoots was raised when my preliminary experiments<sup>6</sup> indicated cytokinin-like activity in apple stem xylem sap. Luckwill and Whyte<sup>7</sup> confirmed this and found the highest kinin activity in sap collected in April which had a concentration equivalent to approximately 0.1 µg kinetin/ml. of crude sap. Chromatography of butanol extracts indicated the presence of at least two active substances.

If the cytokinins of apple xylem sap have an important role in the growth of the shoots, then some indication of this role might be gained by supplying the cytokinins to isolated apple shoots. This communication reports the effects of the synthetic cytokinin benzyl adenine (donated by Shell Chemical Co., Ltd., as SD4901) on apple shoot cultures—work preliminary to studies of the effects of the natural cytokinins of the xylem sap.

M.26 apple rootstock shoots were taken shortly after bud-break, when they were about 1.5 cm long. The bud scales and between one and three of the largest leaves were removed—a requisite for sterility—and the shoots then sterilized<sup>8</sup>. Cultures were also made of 10 mm shoot tips of older vigorously growing M.26 and M.VII rootstock shoots which were about 15 cm long. The tips were grown under sterile conditions in 6 in. × 1 in. test-tubes on "wicks" of Whatman No. 1 filter paper which dipped into 10 ml. of liquid culture medium<sup>9</sup>. Cultures were kept at 25° ± 2° C and illuminated for 16 h daily with fluorescent tubes which gave 500–700 ft.-candles at the tube surface.

The basic medium used was Knop's solution with the minor element solution of Murishige and Skoog<sup>10</sup>, 20 mg/l. NaFeEDTA, and 3 per cent sucrose. The medium was adjusted to pH 5.8 and sterilized by autoclaving at 15 lb./in.<sup>2</sup> for 5 min. The shoots grew to a limited extent in this medium (Fig 1B). Occasionally the shoots rooted, but roots did not develop extensively and never reached lengths beyond about 5 cm. The rooted shoots were very variable, but all were still green after 10 weeks while rootless shoots were turning brown by this time. Furthermore, rooted shoots sometimes produced between three and six more leaves and greater internode extension and leaf expansion than unrooted shoots.

Fig. 1. Effect of benzyl adenine on M.26 shoot cultures (culture period, 5 weeks). A, Inoculum (from shoots about 1.5 cm long); B, basic medium; C, basic medium + 0.1 mg of benzyl adenine/l.; D, basic medium + 1.0 mg of benzyl adenine/l.

The addition of 1 mg of benzyl adenine/l. to the basic medium resulted in sizable increases in leaf production and internode extension (Table 1, Fig. 1). Shoots never rooted when growing with benzyl adenine. Shoot growth with benzyl adenine was greater than with rooted cultures, but this may be caused by the lack of extensive root development when shoots rooted. The benzyl adenine delayed senescence of the shoots, as did roots. Cultures did not grow appreciably after 5 weeks, but those which received benzyl adenine were, in contrast to the controls, still green after 10 weeks.

Table 1. EFFECT OF BENZYL ADENINE ON ISOLATED APPLE SHOOT CULTURES

Source of tips	Benzyl adenine in medium (mg/l.)	No. of replicates	Growth values ± standard errors after 5 weeks		
			Fresh wt. (mg)	Stem length (mm)	No. of leaves and primordia
About 1.5 cm M.26 shoots	—	6	132 ± 12	10 ± 2	13 ± 2
	1	7	562 ± 30	47 ± 7	21 ± 3
About 15 cm M.26 shoots	—	7	222 ± 40	10 ± 3	15 ± 1
	1	6	400 ± 46	18 ± 6	23 ± 3
About 15 cm M.VII shoots	—	6	94 ± 15	5 ± 3	11 ± 1
	1	8	310 ± 38	27 ± 6	16 ± 2

Many of the leaves of shoots with benzyl adenine were small with poorly developed laminae. Anatomical study of internodes indicated that all shoots, whether receiving benzyl adenine or not, had secondary thickening.

The effects of benzyl adenine were greatest on the cultures initiated from the 1.5 cm shoots. These different responses may be caused by differences in reserves of essential metabolites in shoots of different ages. At 0.1 mg/l., benzyl adenine had no marked effect on shoot growth apart from increased callus production in the basal regions. At 10 and 50 mg/l. the cytokinin inhibited shoot extension but produced profuse callus growth.

The isolated shoots seem to require an external supply of cytokinin for growth and the effects of benzyl adenine simulate to some extent the effects of roots. These findings, together with the evidence for cytokinins in the ascending sap, support the view that cytokinins from the roots may be essential for continued shoot growth in apple. Compared with rooted shoots, however, shoots grown with 1 mg of benzyl adenine/l. of culture medium had poorly developed leaves. These abnormal leaves may reflect the possibility that the shoots depend on roots for other organic substances in addition to cytokinins. Analyses of apple xylem sap suggest that the roots supply amino compounds<sup>10</sup> and gibberellin-like substances to the shoots (Jones and Lacey, unpublished results), and possibly these substances are also required for normal shoot development. It is also possible that the cytokinins

of the xylem sap produce effects on shoot growth in addition to those observed with the synthetic cytokinin. These possibilities are under investigation by further experiments with isolated apple shoot cultures.

### Effect of DDT on Photosynthesis in Certain Varieties of Barley

APPARENTLY uniform varieties of barley show striking differences in their reaction to DDT (1,1,1-trichloro-2,2-bis-(*p*-chlorophenyl)-ethane) or certain of its analogues (Fig. 1). Some varieties are resistant to DDT whereas others are susceptible and develop a severe chlorosis some 4–10 days after treatment with sprays containing DDT (ref. 1). DDT is not translocated in the plant to any extent and similar amounts of the insecticide are absorbed by resistant and susceptible varieties<sup>2,3</sup>. The reaction to DDT is controlled by a single major gene with susceptibility dominant to resistance<sup>1,4</sup>.

We have investigated the effect of DDT on two varieties of barley; 'Rika' (susceptible) and 'Proctor' (resistant). To determine whether photosynthesis or respiration is affected by DDT in the susceptible barley, gas exchange in DDT-treated barley leaf tips during alternating periods of illumination (580 ft.-candles) and darkness was studied<sup>5</sup>. In the centre well of a Warburg flask we placed 0.1 ml. of water and 100 mg of leaf tips; the outer compartment contained 2.0 ml. of bicarbonate buffer (0.2 M NaHCO<sub>3</sub>, 0.2 M Na<sub>2</sub>CO<sub>3</sub>; 9:1 v/v). Gas<sup>2</sup> evolution or uptake was recorded in the normal way. Leaves of untreated varieties and of resistant barley treated with DDT reached a peak of photosynthetic activity (oxygen evolution) as seed stores were used up and chloroplasts matured. Senescence of the leaves was accompanied by a progressive fall in photosynthetic activity. In contrast, leaves of susceptible barley treated with DDT showed a decrease in oxygen evolution within 12 h of spraying the plants with DDT. The leaves never reached their normal peak of photosynthetic activity and eventually died as chlorotic symptoms developed (Fig. 2).

The Hill activity of chloroplasts isolated from treated barley was measured by the rate of reduction at pH 6.5 of

Fig. 1. Structure of DDT. Analogues of DDT possessing (a) —OCH<sub>3</sub>, Br, Cl or F in the *para*-positions of the phenyl rings; (b) the C2 ethane hydrogen; and (c) the trichloro- or tribromo-ethane grouping is also toxic to some varieties of barley<sup>2</sup>.

Fig. 2. Gas exchange during successive periods of illumination and darkness after treatment of 8-day-old barley plants with DDT. Experimental details as described in the text. ○, ●, △, and ▲ represent results obtained 0, 4, 7 and 15 days after treatment of plants with DDT. Results from equivalent plants not treated with DDT are shown for comparison. a, Resistant barley, treated with DDT; b, control. c, Susceptible barley, treated with DDT; d, control.

Fig. 3. Photoreduction of 2,6-dichlorophenolindophenol by chloroplasts isolated from barley treated with DDT. Experimental details as described in the text. ○, Barley not treated with DDT; ●, barley 4 days after treatment with DDT. a, 'Proctor' (resistant); b, 'Rika' (susceptible).

the redox dye 2,6-dichlorophenolindophenol (DCIP). The reaction medium, made up in 1 cm cuvettes, contained (per 3.0 ml.): KH<sub>2</sub>PO<sub>4</sub>, 125 μmoles; KCl, 25 μmoles; DCIP, 0.10 μmole; chloroplast preparation containing 30γ chlorophyll. Illumination (14,000 ft.-candles) was provided by two 500 W 'Argaphoto' lamps and reduction of DCIP was followed by the fall in absorption at 620 mμ. Chloroplasts isolated from susceptible barley treated with DDT showed a marked reduction in Hill activity (Fig. 3) whereas those from treated resistant barley showed Hill activity characteristic of unsprayed plants. Four days after spraying the plants with DDT the chloroplasts isolated from susceptible barley showed only about 25 per cent of the Hill activity of chloroplasts from unsprayed plants.

When chloroplasts isolated from unsprayed plants were suspended for 45–60 min in an aqueous suspension of DDT (75–200  $\mu\text{g}$  DDT/mg chlorophyll) chloroplasts from susceptible barley showed a reduction in Hill activity whereas those from resistant barley were not affected. The incubation of chloroplasts in the suspension of DDT for 30–60 min before estimation of Hill activity was essential for this effect to be shown. If chloroplasts isolated from susceptible barley were assayed for Hill activity immediately they contacted the DDT suspension<sup>2</sup> no reduction in Hill activity was observed. The effect of the DDT could be significantly reduced by prior suspension of the chloroplasts in a medium containing DDE [1,1-dichloro-2,2-bis-(*p*-chlorophenyl)ethylene], an analogue of DDT which is not toxic to either variety of barley.

Fixation of  $^{14}\text{CO}_2$  into ethanol soluble products of photosynthesis<sup>6</sup> by treated plants or into phosphoglyceric acid by carboxydismutase preparations<sup>7</sup> from treated plants was quantitatively the same in both susceptible and resistant varieties of barley. The proportion of soluble material from susceptible barley 8 days after treatment was, however, increased some 35–40 per cent compared with the similarly treated resistant variety. The material accumulating in the susceptible barley treated with DDT seems to be sugars (personal communication from J. D. Hayes).

The results suggest that in susceptible varieties of barley DDT affects the light reaction in photosynthesis. Further investigations to find the precise site of action of DDT on the photosynthesis of susceptible barley are now in progress.

### Effects of Actinomycin D on Development in Pupae of *Tenebrio molitor*

Ilan, Ilan and Quastel have reported<sup>1</sup> that modified adults emerge when 0.16  $\mu\text{g}$  of actinomycin D is injected into the pupae of *Tenebrio molitor* at any time during the pupal period. The duration of pupation is said to be unaffected. The adults which emerge are reported to have an adult head and thorax, but the abdomen has pupal gin traps, urogomphi and pupal cuticle on the posterior segments. Injected pupae do not develop wings. The interest in the effects of actinomycin D on development stems from the way in which the drug is known to interfere with DNA dependent RNA synthesis. The pupal development of insects must involve the transcription of the genetic information coded in DNA into the specific proteins of the various tissues by the formation of messenger RNA (*mRNA*). Ilan *et al.* interpret their observations by supposing that the *mRNA* for the development of the head and thorax is present from the first day of pupation and that abdominal development is sensitive to actinomycin D until the last day of the pupal period.

My own observations, made during a detailed study of the effects of drugs on the developmental pattern of *Tenebrio molitor* pupae, do not agree with the results of Ilan *et al.* Pupae weighing  $100 \pm 10$  mg, kept at 31° C, emerge on the seventh day after pupation. Injection into pupae of different ages of 0.04  $\mu\text{g}$ , 0.08  $\mu\text{g}$ , 0.16  $\mu\text{g}$ , and 0.32  $\mu\text{g}$  of actinomycin D in 1  $\mu\text{l}$ . of 0.9 per cent sodium chloride produced six characteristic patterns of epidermal differentiation (Table 1). Controls were injected with 1  $\mu\text{l}$ . of 0.9 per cent sodium chloride. The control animals and those injected with 0.04  $\mu\text{g}$  of actinomycin D all emerged as normal adults on the seventh day (class VI). When the pupae injected with 0.16  $\mu\text{g}$  were inspected on the seventh day, four classes were observed (classes I, II, III and V). By the ninth day after pupation however, some of Class II had completed cuticle formation, the abdomen forming a second cuticle of pupal type (class IV).

The degree of inhibition of epidermal differentiation is dependent on both the dose and the day on which the actinomycin D is injected. Injection of any dose after the fourth day, or injection of 0.08  $\mu\text{g}$  on any day, results in class V or class VI animals only (Table 2).

The description given by Ilan *et al.* of their "modified adult" suggests at first, that these animals might correspond with my class IV, in which the abdomen forms a second cuticle of pupal type. They state, however, that a new cuticle is not formed over the abdomen of modified adults, which excludes my class IV and suggests my class III. I believe, however, that these authors were in fact observing class V animals in which the adult cuticle is formed, but is still enclosed by the pupal cuticle. Their photograph of a modified adult appears to show a tanned abdominal cuticle; a pupal cuticle does not tan. Also, although the abdomen has not shortened to the adult

Table 1. CLASSES OF RESULTS OBTAINED AFTER THE INJECTION OF ACTINOMYCIN D INTO THE PUPAE OF *Tenebrio molitor*, IN DECREASING ORDER OF INHIBITION OF EPIDERMAL DIFFERENTIATION

Class I	No adult differentiation of epidermis.
Class II	Sclerotized adult cuticle formed on the limbs and head appendages only.
Class III	Head and thorax form adult cuticle, the abdomen forms no new cuticle.
Class IV	Head and thorax form adult cuticle, the abdomen forms a second pupal cuticle. External genitalia are present.
Class V	Complete adult cuticle formed, but animals fail to emerge from pupal cuticle over abdomen. Abdomen does not shorten fully. Wings do not expand. Some tanning of ventral abdominal cuticle always occurs.
Class VI	No inhibition occurs; full emergence of normal adults on the seventh day.

Total number injected for each group in brackets.

form, it is not pupal in shape, and external genitalia appear to be present. The suggestion that their modified adults are indeed class V animals is supported by the fact that I have obtained class V animals after the injection of pupae of any age, but I could not produce class III animals either by injection after the fourth day or by injection of doses less than 0.16  $\mu$ g. In my experiments, the injection of 0.08  $\mu$ g of actinomycin D produced 60 per cent class V animals and the rest emerged normally which compares with the 70 per cent of "modified adults" obtained by Ilan *et al.* after injection of the same dose.

Ilan *et al.* used pupae heavier than mine, and it seemed possible that 0.16  $\mu$ g is below the critical dose in such pupae for inhibition of the formation of adult abdominal cuticle. To check this, fifty animals of different ages which weighed between 110 and 120 mg were injected with 0.16  $\mu$ g of actinomycin D and incubated at 28° C—conditions which correspond exactly with those of Ilan *et al.* All but five formed an adult abdominal cuticle. It is worth noting that, by the time of emergence of the adult cuticle in control pupae, much of the pupal cuticle has been digested and only a fine transparent sheath remains to be shed. In most of the injected pupae in which emergence is inhibited, the pupal cuticle remains undigested and opaque, giving the superficial appearance of a lack of adult cuticle over the abdomen. I therefore suggest that Ilan *et al.* did not observe the inhibition of some process concerned with cuticle formation, but the inhibition of one of these later events leading to the final successful eclosion of the adult.

My results, shown in Table 2, seem to indicate separate determinations for the formation of a second cuticle on the limbs, the head and general thorax, and the abdomen, because, depending on the time of injection and the dose of actinomycin D, development of a new cuticle in one or more of the three regions can be inhibited or modified. Ilan *et al.*, on the other hand, claim to have shown two stages; the formation of an adult cuticle on the head and thorax was said to be insensitive to actinomycin D throughout pupation, while the formation of an adult cuticle on the abdomen was sensitive to actinomycin D until the last day of pupation. It is tempting to suggest that the three stages in the formation of the cuticle, which I have found to be independently sensitive to actinomycin D, indicate that three separate mRNAs are involved.

This work was carried out during the tenure of an SRC studentship and under the supervision of Dr Janet Harker. The actinomycin D was a gift from Merck, Sharp and Dohme.

### High Concentrations of Haemoglobin A<sub>2</sub> in Malaria Patients

THE A<sub>2</sub> fraction of normal haemoglobin (Hb-A<sub>2</sub>) has been described by Kunkel and Wallenius in 1955<sup>1</sup> and soon after it was confirmed that this fraction doubled its normal values or reached even greater concentrations in  $\beta$ -thalassaemia minor<sup>2</sup>, and it has been found to be increased in pernicious anaemia in relapse<sup>3</sup>, in patients with Hb-Zürich<sup>4</sup>, in recipients of foetal haemopoietic tissue<sup>5</sup> and in a single case of hereditary spherocytosis<sup>6</sup>. It is easy to exclude the last four conditions, and so greater concentrations of Hb-A<sub>2</sub> than normal are considered specific for the diagnosis of  $\beta$ -thalassaemia minor.

In 1960, while studying Hb-A<sub>2</sub> in starch block electrophoresis on 118 samples of Venezuelan Paraujano Indians,

105 were found with a mean value of  $2.32 \pm 0.58$  per cent of the total haemoglobin. The other thirteen samples showed larger values than the upper normal level, but less than the smallest concentration found in thalassaemia minor. Deficiency of serum vitamin B<sub>12</sub> was excluded in this population<sup>7</sup>.

In 1965 another group of the same Indians was investigated. Again high concentrations of Hb-A<sub>2</sub> were found in twenty-five out of 140 people:  $3.79 \pm 0.45$  per cent of the total haemoglobin (my work, in preparation). If these have thalassaemia minor we would expect about 3 per cent of thalassaemia major, which does not correspond with information given by local physicians. Thus there ought to be another cause producing high concentrations of Hb-A<sub>2</sub>.

Results of X-ray studies on ancient skulls<sup>8</sup> have suggested that the Peruvian Incas, as well as the Mayas of Central America, could have disappeared because of a fatal osteoporotic process similar to thalassaemia. Concentrations of Hb-A<sub>2</sub> studied in various Indian populations of South America (Table 1), however, have not confirmed this hypothesis, which indicates that if  $\beta$ -thalassaemia is prevalent among the still living Indians of the American continent it is in a very small proportion and never as great as suggested by that report. Cabannes, Bourrier and Larrouy<sup>9</sup> have raised this question again when describing a very high percentage of what they considered to be  $\beta$ -thalassaemia and hereditary persistency of high Hb-F in French Guiana Indians.

The opportunity arose recently to study the concentrations of Hb-F and Hb-A<sub>2</sub> in several cases of acute and chronic *Plasmodium vivax* malaria (including those of myself and my wife, whose Hb-A<sub>2</sub> concentrations had been previously within normal limits) and the conclusion was reached that malaria infection produces significant changes in the pattern of haemoglobin, especially the increase of Hb-A<sub>2</sub>, which could very easily be mistaken for  $\beta$ -thalassaemia minor. This indicates the need for a new interpretation and further studies on the subject.

Blood was collected by venipuncture and haemoglobin solution was prepared by the method of Houchin and Robinette<sup>10</sup>. Starch block electrophoresis for Hb-A<sub>2</sub> quantification was carried out according to the technique of Kunkel and Wallenius<sup>1</sup>. Concentrations of Hb-F were determined using the technique of Betke *et al.*<sup>11</sup> and Singer *et al.*<sup>12</sup>.

Results obtained for Hb-A<sub>2</sub> (Table 2) are significantly larger ( $P < 0.001$ ) than the mean value of normal subjects obtained in our laboratory (Table 1). Even by simple inspection, the starch block electrophoresis plate shows high Hb-A<sub>2</sub> in malaria patients (Fig. 1).

Table 1. Hb-A<sub>2</sub> VALUES IN VARIOUS NORMAL SOUTH AMERICAN POPULATIONS

Population	No. tested	Range	Hb-A <sub>2</sub> mean	S.D.	Reference
Venezuela					
Natives non-Indian	76	1.47-3.37	2.46	$\pm 0.48$	
European residents	19	1.25-3.14	2.25	$\pm 0.57$	7
Paraujano Indians	105	1.25-3.49	2.32	$\pm 0.58$

Ya 25	4.0	0.4	—	Chronic

Fig. 1. Visualization of Hb-A<sub>2</sub> by means of starch block electrophoresis using barbital buffer pH 8.6, 0.1 molar, 400 V, 75 m.amp, for 18 h at 4° C. By comparison with both normal and  $\beta$ -thalassaemia minor controls the Hb-A<sub>2</sub> fraction of patients with malaria is clearly increased.

At the moment there is no clear physiopathological explanation of the increase of Hb-A<sub>2</sub> in malaria, as there is also no valid interpretation of the increase occurring in the other conditions mentioned. Immunologically, malaria infection is an extraordinary stimulus<sup>13</sup>. The increase of Hb-A<sub>2</sub> could possibly indicate a more generalized body reaction in the presence of malaria, including other than the immunological system, in this case the haemoglobin synthesis. Another possibility is that not all cells have an equal amount of Hb-A<sub>2</sub> and that *Plasmodium* could have a selective preference for cells with a lower amount of Hb-A<sub>2</sub>. The protective effect of Hb-S in African children<sup>14</sup> is known and it has been suggested that congenital immunity against malaria disappears at the same time as Hb-F (ref. 15). Our finding may represent another proof that *Plasmodium* only metabolizes Hb-A efficiently.

Studies on sheep haemoglobin have shown that animals with Hb-A are more resistant to infection in the small bowel by *Haemonchus contortus*, a blood sucker nematode, than those having Hb-AB (ref. 16). This characteristic, the physiopathological mechanism of which has not been clarified, is a good example of possible interaction between a type of haemoglobin and a typical environmental disease. This apparently may also occur in malaria infection.

On the other hand, it is justified in view of these findings to re-investigate certain populations where malaria infection is or has been endemic and which also show an excessive proportion of  $\beta$ -thalassaemia minor, such as Italy, Greece, Sardinia and French Guiana. The population of Paraujano Indians in which high concentrations of Hb-A<sub>2</sub> have repeatedly been found is known to have had periodical sieges of malaria, having positive cases of *Plasmodium vivax* as recently as 1957.

We thank Mrs Marina de Peraza for technical assistance.

## PSYCHOPHARMACOLOGY

### Factors determining the Effect of Chlorpromazine on the Food Intake of Rats

CHLORPROMAZINE often alters body weight and food intake in patients<sup>1</sup> and animals<sup>2-5</sup>, but the results of the animal studies conflict. Actions of chlorpromazine on food intake are also interesting because there has been much work on the effects of this drug on animal learning and performance with food used as the reward, and these could be confounded with effects on hunger.

Experiments in which rats were maintained on daily cycles of severe food deprivation have indicated that chlorpromazine decreases the food intake<sup>2,3</sup>. When unlimited food was available, or when the animals could at least partially satisfy their appetites, chlorpromazine increased the food intake<sup>4,5</sup>. Some authors<sup>6</sup> have suggested that food deprivation and the consequent level of hunger determines whether a rise or a fall of food intake occurs after chlorpromazine is given. The falls occurred in rats which had become accustomed to eat a large amount at a time of day when normally they ate little, and so it seems necessary to consider whether the effect of the drug was related to this.

In none of these experiments, however, were direct comparisons made between rats maintained on different feeding cycles, so other differences between the various experiments might account for the conflicting results. The experiments described here were planned so that the same measures of food intake could be obtained, regardless of the cycle of food deprivation on which the rats had previously been maintained.

One group of rats, the "limited time" of feeding group, was allowed to eat as much as it could, but only during 2 hours each day during the week before testing. A second group ("limited amount" of feeding) had its food intake reduced in a different way; the possibility of learning to eat a large amount in a short time was eliminated by limiting the quantity of food supplied to that needed to maintain body weights at 80 per cent of their initial weight. A third group of rats was given unlimited food at all times—the "satiated" group. All groups had free access to water throughout.

Each rat was tested twice, once after subcutaneous injection of 5 mg/kg chlorpromazine and once after saline injection. The order of the treatments, which were separated by 2 clear days during which the appropriate feeding cycles were reimposed, was counter-balanced within each group. On the test days, food and water were made available in unlimited quantities 30 min after injection to all groups of rats for 24 hours, and food and water intake and the amount of food spilt were measured at intervals. Male hooded rats were used, 70–100 days old, housed singly at temperatures of 70°–74° F. Powdered rat diet was available from open cups.

The feeding regimes described reduced the body weights of the limited time and limited amount of feeding groups to 75.5 per cent and 74.5 per cent, respectively, of their initial free-feeding weights, so that these two groups were at effectively the same level of food deprivation when tested. After saline injection, there was very little difference in the intake of food and water between the two groups (Table 1). Thus there was no evidence that the rats had learned to eat more during the 2 h feeding period than would be expected from the high level of hunger.

Table 1. FOOD AND WATER CONSUMED DURING ACCESS FOR 2 H TO UNLIMITED FOOD AND WATER BY RATS PREVIOUSLY MAINTAINED ON DIFFERENT CYCLES OF FOOD DEPRIVATION

	Limited time of feeding group	Limited amount of feeding group	Satiated group
Food intake	14.1 g	13.2 g	2.6 g
Water intake	12.7 ml.	11.1 ml.	2.3 ml.

As one would expect, the satiated group ( $n=7$ ) ate and drank significantly less ( $P<0.001$ , Mann-Whitney U-test) than the deprived groups. The differences between the limited amount ( $n=6$ ) and limited time ( $n=7$ ) groups were not significant ( $P>0.2$ ).

Fig. 1 shows the food intake after the administration of chlorpromazine as a percentage of the intake after saline injection. The Walsh test<sup>4</sup> for related samples was used to test the significance of drug effects because homogeneity of variance need not be assumed. The overall pattern is clear; during the first 2 h of testing the intake of food by satiated and both types of deprived rats was depressed by chlorpromazine, but after that the intake rose and remained relatively high for 22 h. The overall food intake during the 24 h of the tests rose by about 15 per cent ( $P<0.05$ ), so that the rises more than compensated for the initial falls. Chlorpromazine also increased the amount of food spilt. In another experiment, neither smaller nor larger doses stimulated food consumption during the period of 2 h after injection, which suggests that the time course described was not merely a consequence of changing concentrations of the drug in the tissues.

These results were unexpected: the time after injection was an important factor which determined whether chlorpromazine inhibited or stimulated food intake. Screening tests for appetite-reducing drugs are usually carried out within 2-3 h of administration, and may thus give misleading results with chlorpromazine. In patients<sup>5</sup>, chlorpromazine usually causes a gain in weight and sometimes even obesity, and it is also used in the treatment of anorexia nervosa, but these effects may be due to water retention<sup>7</sup> or other factors.

Fig. 1. Changes in food intake of three groups of rats during three consecutive time intervals after 5 mg/kg chlorpromazine. LT, Limited time of feeding group ( $n=7$ ); LA, limited amount of feeding group ( $n=6$ ); S, satiated group ( $n=7$ ). The dashed line at 100 per cent is food intake after saline injection. The levels of statistical significance of the changes from food intake after saline are shown (Walsh test, two-tailed). Measurements of food intake began 30 min after injection. It can be seen that food intake first fell and then rose, but was also influenced by the particular feeding cycles on which the rats had been maintained for 1 week before the drug experiments began.

Surprising differences between the groups emerged 2-7 h after the start of testing. The satiated group showed very variable responses. The large standard deviation is shown in Fig. 1; according to the Walsh test the effect of the drug was not significant, although the mean rose. The rise in the limited time of feeding group was consistent and statistically significant, but there was no effect in the limited amount group. Thus appropriate deprivation of food made it easier to obtain statistically significant increases, but with only one particular type of deprivation did the drug have any effect at all. This is a case where the overt behaviour of two groups of rats with different previous experiences was not detectably different after saline injection (Table 1), but where previous experience was apparently a factor in determining responsiveness to a drug. Previous experience also modifies reactions to psychoactive drugs in other behavioural tests<sup>8</sup>.

Water intake also depended on the time of testing after injection. At first chlorpromazine inhibited the water intake of all groups, but later the water intake rose, at about the same time as food intake rose.

Because 5 mg/kg of chlorpromazine is a fairly large dose, a general depressant action could have produced the fall in consumption of food and water which occurred soon after injection. This could hardly apply to the subsequent increases which more than compensated for the fall, despite the fact that general activity is usually found to be depressed for several hours after chlorpromazine is given. Furthermore, drugs which produce heavy sedation may at the same time stimulate eating<sup>4</sup>.

The experiments described here therefore suggest that the food and water intakes of rats treated with chlorpromazine are mainly dependent on the time of testing after injection, but can also be influenced by previous experience of particular types of feeding cycles. Hunger induced by both limited time and limited amount feeding cycles is widely used to motivate rats used for learning experiments. Although one should be cautious in inferring effects on motivation from changes in the intake of food or water<sup>9</sup>, the present experiments show that fluctuating levels of hunger and thirst may be expected up to at least 7 h after injection of chlorpromazine and should be considered when interpreting the results of experiments on learning in animals.

I should like to thank Dr Hannah Steinberg for advice and discussion. This work was supported by a Smith, Kline and French studentship and a research grant from the National Institute of Mental Health, US Public Health Service.

## PSYCHOLOGY

### Time required for Judgements of Numerical Inequality

AN educated adult can tell which of two digits is the larger with virtually no uncertainty. By what process is this accomplished? On the one hand, it is conceivable that such judgements are made in the same way as judgements of stimuli varying along physical continua. On the other hand, numerical judgements may be made at a

different, less perceptual and more cognitive, level. For instance, the task may be one of memory access, each possible pair of numerals being stored with a corresponding inequality sign; or perhaps some sort of digital computation is performed, such as counting the space between the two numerical values.

One way of exploring the nature of such processes is by examining the time which they require. Judgements of inequality for length of lines, pitch and colour are known to require longer time the smaller the difference between two stimuli<sup>1</sup>. Moreover, such judgements tend to show a psychophysical function—a given difference between two stimuli evokes a quicker reaction the smaller their absolute values<sup>2</sup>. Thus, if humans judge differences between numerals in the same way as differences along physical continua, reaction times should be inversely proportional to the difference between two numbers and smaller for smaller numbers. If, instead, the process involves direct memory look-up, there is little reason to expect such relations. Finally, if the process involves counting of the number space between the two numerals, then reaction time should be directly proportional to the difference. To explore this question, we have measured the time required for judging which of two single digit numerals is the larger.

Ten female undergraduates of Stanford University served as subjects. Each stimulus consisted of two numerals each of one digit typed 2.5 cm apart on a white background. Every non-repeating pairing of the numerals 1 to 9 was used. Each digit appeared twenty-four times on the left and twenty-four times on the right; each pair three times as  $x \dots y$  and three times as  $y \dots x$ . The order was random. Subjects were instructed to throw the left-hand or right-hand of two switches according to whether the digit on the left or right was the larger. They were told to respond as quickly as possible without making errors.

The stimuli were presented through a half-silvered mirror, and were not visible until a light and timer were simultaneously activated.

Fig. 1 shows that the decision time was an approximately linear inverse function of the numerical differences between the two stimulus digits. The negative correlation is significant ( $r = -0.63$ ) ( $P < 0.01$ ). Error data (Fig. 2) show a similar trend.

We explored a number of possible equations for describing these data, and found that a reasonable fit is of the same general class as those usually found to describe discrimination reaction times for differences between physical quantities such as pitch of tone and length of line (much of the relevant literature is reviewed in ref. 3). For example, the equation  $RT = K \log$  (larger/larger-smaller) which Welford<sup>3</sup> proposes as a general model for

Fig. 1. Reaction time as a function of numerical difference between the two stimulus digits.

Fig. 2. Distribution of errors as a function of numerical difference between the two stimulus digits.

such situations yields a product-moment correlation coefficient of 0.75 for our data. Thus the function resembles classical psychophysical functions, in that the ratio of the two stimulus numerals is more closely related to  $RT$  than is the absolute difference between them.

These results strongly suggest that the process used in judgements of differences in magnitude between numerals is the same as, or analogous to, the process involved in judgements of inequality for physical continua.

A possible artefact in these results arises from the fact that in the set of pairs used the numerically larger digits were more often "correct" (that is, they corresponded to the proper switch) and were also more often found in pairs with larger differences. If subjects respond more quickly to single digits with higher probabilities of being "correct", this correlation among the stimulus materials would produce a spurious appearance of shorter times for pairs with larger differences. To control for this possibility, a second experiment was run in exactly the same manner as the first, except that a new set of pairs was used. For comparisons between certain pairs of this set the size of numerical differences between the two members varied while the likelihood of the component single digits being correct over the entire set was constant. For comparisons between certain other pairs the effect of probability of their members being "correct" over the entire set varied while the numerical difference between the numbers was constant. Numerical differences between pair members produced a statistically significant effect ( $P < 0.05$ ), while variations in probability correct did not ( $P < 0.10$ ). It thus seems safe to assume that numerical difference between pair members was the critical variable in the first experiment.

The decision process which these data suggest is one in which the displayed numerals are converted to analogue magnitudes, and a comparison is then made between these magnitudes in much the same way that comparisons are made between physical stimuli such as loudness or length of line.

This research was conducted while one of us (R. S. M.) was supported by a US National Science Foundation graduate fellowship.

## BOOK REVIEWS

### HEROIC ANTARCTIC EXPLORATION

#### South to the Pole

The Early History of the Ross Sea Sector, Antarctica. By L. B. Quartermain. Pp. xx+481+26 plates. (London: Oxford University Press, 1967.) 75s. net.

MR LESLIE QUARTERMAIN is a scholar and Antarctic enthusiast who has delved deeply into published and unpublished records of the heroic era of Antarctic exploration. He is also a practical historian who, in his capacity as information officer with the Antarctic Division of New Zealand's DSIR, has restored huts used by Scott and Shackleton so that all who visit McMurdo Sound can see how these expeditions lived.

*South to the Pole* tells a story which runs from the time of the early Polynesians to the 1920s but has the unusual geographical limitations of 160° E. to 150° W. and south of 60° S. Within this area, the lands and islands form the Ross Dependency which is administered by New Zealand. Especially in these days of the Antarctic Treaty, one could criticize the division of Antarctic history into sectors, but the later history of the sector does in fact have a unity of its own. The earlier history consists of relevant sections of the voyages of Cook, Bellingshausen, Wilkes, Balleny and one or two others, plus the first major exploration of the Ross Sea under Sir James Clarke Ross in 1840-42.

After Ross, little exploration of the sector took place until the turn of the century, although many scientists pressed for action, as we see from articles in *Nature* by the German hydrographer in 1872, by H. R. Mill in 1896, and by resolutions of the International Geographical Congress in 1895. This pressure culminated in a series of national expeditions starting in 1901, Scott's British Antarctic Expedition of 1901-04 being the first major one to explore to the south of New Zealand. Before this took place, however, a Norwegian schoolteacher from Australia, Borchgrevink, secured the backing of the press baron Sir George Newnes and organized the Southern Cross expedition of 1898-1900. The party had its shortcomings, but nevertheless was the first to overwinter on the Antarctic continent and it seems to have received less than due recognition from the President of the Royal Geographical Society, Sir Clements Markham, and from Scott.

While this expedition was in the field, the Royal Geographical Society in co-operation with the Royal Society succeeded in raising funds from private and government sources to send out the British Antarctic Expedition of 1901-04. Relations between the two societies did not stay happy, because of differences over finance and the leadership of the land parties. These disputes seem to have had some lasting effect, for although the two societies have co-operated in many ways since, no further expeditions have taken the field with the two societies accepting joint responsibility for their organization until the Royal Society/Royal Geographical Society Brazil Expedition of 1967.

The stories of the period 1901-14 are well known, but they are retold in an interesting way with ample references to original source material. The assessment of the person-

alities and respective merits of the leaders of this period seems very fair and free of the more usual emotional assessment. Due prominence is given to the little known but heroic story of the Ross Sea section of Shackleton's Imperial Trans-Antarctic Expedition of 1914-17. Their shore party was equivalent to Hilary's section of Fuchs' subsequent Trans-Antarctic Expedition. Radio communications were too primitive to establish communication with the outside world. The ship which was intended to stay with the wintering party in McMurdo Sound was driven to sea in a storm in early autumn, leaving those on shore with inadequate stores and clothing. These men, not knowing that Shackleton had failed to land from the *Endurance* in the Weddell Sea, succeeded against gross odds in laying the depots expected by the trans-Antarctic group. One of the shore party died during the return journey, and two more lost their lives by attempting the last stage between huts in McMurdo Sound before the sea ice was firm enough. Finally, Captain J. K. Davis on the *Aurora*, with Shackleton on board, rescued the survivors in January 1917.

The history is taken into the 1920s with an account of the development of early whaling operations in the Ross Sea. It stops before the opening of the mechanical era which began with Byrd's first expedition.

The book does not attempt to provide a history of early scientific research in Antarctica in relation to the present day efforts. Quartermain provides instead an interesting, accurate and balanced assessment of the various expeditions and their leaders in the light of present day information on Antarctica. As a volume it will clearly join the classics of the history of general Antarctic exploration.

G. DE Q. ROBIN

### HIGH ENERGY PHYSICS

#### High Energy Physics

Vol. 1. Edited by E. H. S. Burhop. (Pure and Applied Physics; a Series of Monographs and Textbooks. Vol. 25.) Pp. xi+499. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 176s.

High energy physics is the title which, for want of a more appropriate description, is nowadays assigned to that branch of physics which formerly went under the name of elementary particle physics. It is the frontier of physics, concerned with the most basic laws, and it is not surprising that it has attracted and continues to attract the most talented and ambitious among physicists. Although high energy physics is still far from answering the questions which it poses for itself, it has made great progress in the thirty or forty years of its existence and continues to do so. It is now a vast subject embracing a wide class of phenomena ranging from very low energies of the order familiar to low-temperature physicists to the very great energies obtainable only from cosmic rays and from the giant accelerators. It has an army of practitioners and its demands on the exchequer are now the subject for national and international debate. I am therefore inclined to agree with Professor Burhop that "it is now extremely difficult to envisage a work both comprehensive and up to date, written by a single author" on this subject.

Professor Burhop has sought to cover the main branches of high energy physics by collecting seventeen chapters on various subjects contributed by experts in their respective fields. The choice of subjects and the manner in which they are treated necessarily reflect the preferences of the editor and of the various authors.

Of the five chapters in the present volume, the introductory chapter by V. F. Weisskopf is a popular account, reprinted from *Science*, of the present status of elementary

particle theory. In simple language, in a few pages, Professor Weisskopf explains the questions which must be answered and describes current attempts to do so.

The first substantive chapter (170 pages) by G. Breit and R. D. Haracz is appropriately devoted to "Nucleon-Nucleon Scattering". It was precisely in order to learn more about nuclear forces that the first accelerators were built. It was believed that all that one needed to ascertain the detailed properties of nuclear forces was to perform nucleon-nucleon scattering experiments at sufficiently high energy. We now know that this is frustrated by production of  $\pi$ -mesons or pions, and of the totally unexpected "strange" particles. Even at energies low enough for meson production to be neglected, the nucleon-nucleon interaction has turned out to be a very complicated one, at least according to the current description. This chapter describes, with the thoroughness which we associate with Professor Breit, the great amount of work, much of it by Breit and his collaborators, which has gone into the analysis of nucleon-nucleon scattering experiments.

The next chapter (146 pages) on "Pion-Nucleon Interactions" is by J. Hamilton. The discovery of pions, predicted by Yukawa as the quanta of the nuclear force-field, was a great triumph of theoretical physics which earned Nobel Prizes both for its prophet and for its discoverer. A knowledge of pion-nucleon interactions is essential for a fundamental understanding of the nucleon-nucleon force and much of the credit for our present comprehension of the pion-nucleon interaction goes to Professor Hamilton and his school. It was suggested in the mid-fifties that the dispersion relations which express the condition of relativistic causality could provide the basis for a dynamical theory of strong interactions. Since then many exaggerated claims have been made on its behalf, but almost the only quantitative application of these relations has been to elastic pion-nucleon scattering, of which this chapter gives an authoritative account.

A much shorter chapter (50 pages) by T. A. Griffy and L. I. Schiff is entitled "Electromagnetic Form Factors". The authors have been closely associated with the high energy electron scattering experiments, first systematically studied at Stanford, which have played an important part in the determination of nuclear and nucleon structure. The interaction is known so that information is directly available on nuclear charge and current distributions, the parameters describing which are usually called form factors. Most of the chapter is devoted to the analysis of elastic electron scattering from nucleons, deuterons and trineutrons, and to a discussion of the dynamical origin of the nucleon form factors. Electro-production of pions is briefly mentioned.

The concluding chapter (90 pages) by P. T. Matthews is on "Unitary Symmetry". The first half, together with an excellent appendix, provides a clear and elegant exposition, assuming no previous knowledge of group theory, of the SU(2) and SU(3) groups and their application to particle physics, the high point of which was the discovery of the theoretically predicted  $\Omega^-$  particle in 1964. The latter half of the chapter describes theories, which were the sensation of 1964-65, which attempted to combine internal and space-time symmetries. As stated briefly in a note added in proof, it is now clear from the work of Professor Matthews and others that these theories all violate one or other of our most basic theoretical expectations. This part of the chapter is therefore mainly of pedagogical or historical interest.

The editor states that this is primarily a reference book but expresses the hope that the individual chapters provide sufficient basic material to be useful to graduate students entering the field. This is certainly correct but, because the price may deter some students, this purpose might be better served by re-issuing the main articles as separate small books.

P. K. KABIR

## MÖSSBAUER INDEX

### Mössbauer Effect Data Index 1958-1965

By Arthur H. Muir, jun., Ken J. Ando and H. M. Coogan. Pp. xviii+351. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1966.) 72s.

THE implications of Mössbauer's discovery, in 1958, of recoilless emission and absorption of  $\gamma$ -rays were rapidly recognized. Here is a spectroscopic technique with sufficient but not too much resolution for studying the interactions between nuclei and their electronic environments. Workers and results have multiplied explosively. A "nine year wonder" is an inappropriate description of the situation, because interest shows no sign of diminishing.

In this volume, members of the North American Aviation Science Center have published a complete index of Mössbauer work for the period 1958-65. Limited, privately circulated editions have appeared previously. An IBM computer has been used for information storage and retrieval and the body of the work consists of reprinted computer output. As a result, there are many oddities of notation and abbreviation. These do not, however, make the index difficult to use—indeed, it is of outstanding value.

The references to journals are first classified by experiment—nuclear transition involved, source and absorber materials, temperatures and so on. References to theoretical work, instrumentation, books and reviews are listed at the end of this section.

In the "Master Reference Section", all references are listed by their code numbers, involving year of publication and the initial letter of the first author's name. The effect is to produce a more or less chronological ordering. In the final section, references are listed under the names of each author.

Much additional useful information is to be found tucked away in this volume, which will surely find its way on to the shelves of all Mössbauer workers.

R. E. MEADS

## DEVELOPMENT OF A TECHNIQUE

### Electron Spin Resonance

A Comprehensive Treatise on Experimental Techniques. By Charles P. Poole, jun. Pp. xxvii+922. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1967.) 240s.

THE sub-title of this book, "A Comprehensive Treatise on Experimental Techniques", is a correct description. The work is reasonably comprehensive and the accent is on experimental techniques.

We are told in the preface that the book is primarily intended for those who might wish to build their own spectrometers or to modify existing spectrometers. Much less attention is given to the results which have been obtained or to their theoretical interpretation. Nevertheless, nearly 1,000 pages have been written and the book will be of great use to practitioners in the field of electron spin resonance instrumentation. This will mean that physicists will be more interested than chemists because most chemical laboratories interested in this technique are now equipped with commercial instruments of very advanced design which few people would hope to better, or even equal, on their own.

Had the book appeared some twelve years ago at a time when chemists were becoming really interested in this technique, it would have been invaluable, and most of what has been said now could indeed have been said at that time.

In covering this field at great depth, the author has been somewhat indiscriminate and many of the chapters

seem to be unnecessarily long and parts of them are unnecessarily elementary. Many of the circuits are of historical interest and would not be used in practice, and those areas where instrumentalists are currently making very important advances, such as ENDOR, are, unfortunately, neglected. So, for example, ENDOR is given about thirty-four pages, which is about the same space allocated to vacuum systems. This means that some recent important work in this field has been overlooked. In short, this book, despite its high price, can be strongly recommended to physicists who wish to learn about the historical development of this technique and who wish to construct their own instruments for special purposes, but will be of little use to the experimentalist who wishes to use electron spin resonance in a routine manner.

M. C. R. SYMONS

## ABSTRACT ANALYSIS

### Functional Analysis

(Academic Press Textbooks in Mathematics.) By George Bachman and Lawrence Narici. Pp. xiv + 530. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.) 116s.

THIS book is intended as an introduction to functional analysis, the part of mathematics concerned with infinite dimensional vector spaces. After some preliminary material on finite-dimensional spaces and on metric and general topology, there is a thorough discussion of the fundamental properties of Banach spaces, including the Hahn-Banach theorem, the principle of uniform boundedness, the closely related continuous inversion and closed graph theorems, and related questions. A brief section on spectral theory is followed by an introduction to Banach algebras, going as far as the Gelfand representation. The last third of the book is devoted to spectral theory in Hilbert space; a number of proofs of the spectral theorem for self-adjoint operators (bounded and unbounded) are discussed in detail. The treatment of normal operators contains some novel features derived from recent research.

The book is long for the material it covers; proofs are spelled out in great detail, and there is much incidental comment. There are numerous exercises for the reader, mainly of a quite straightforward character. The book will be useful for reference to student and teacher alike, but might be found rather heavy going by a beginner wishing to acquaint himself with the elements of the subject.

F. SMITHIES

## METAL-METAL COMPOUNDS

### Intermetallic Compounds

Edited by J. H. Westbrook. (Wiley Series on the Science and Technology of Materials.) Pp. xvii + 663. (New York and London: John Wiley and Sons, 1967.) 235s.

DR WESTBROOK claims, rightly, that this is the first comprehensive treatment of this subject in fifty years. It is therefore all the more welcome.

Considerable effort is now being directed towards metallic compounds of all types, largely as a result of the state of near exhaustion in the further development of metallic alloys. This volume deals mainly with the structure, transformations and properties of metal-metal compounds, but because many of these are operative agents in improvement of the properties of metallic alloys, they are of interest to both metallurgists and materials scientists.

The editor presents a historical sketch in the first chapter, concise and informative, and rather unusual for a

book originating in the United States, where history tends to be more introverted. Excellent reviews of bonding theory and experimental evidence for bonding characteristics are given in the second part, and although one or two are a little too brief, they form an excellent introduction to the subject for the research student. The chapters in the third part, on crystal structure, incorporate some well executed illustrations to assist understanding of the text in a way which puts the average undergraduate textbook to shame. Many matters of metallurgical interest are featured here.

The fourth part of the book, on micro- and sub-structure, is short, and perhaps the least successful is the chapter entitled "Lattice Defects", which adds little and omits much which is relevant. Formation and stability are well covered in the fifth part and so are kinetics and transformations in the next part. The final part of the book comprises seven chapters on properties, from mechanical to super conductivity, and much of this will be well thumbed in library copies. It is disappointing, however, to find little reference to thermal properties except for thermoelectricity, but in recent years this has become almost a constant feature of any book dealing with the properties of materials. It would appear that only mechanical strength and electronic applications are of any significance to industrial and academic research alike.

I welcome an index including not only author and subject entries but also a complete list of the compounds mentioned. The star-studded international cast includes twenty-four authors from the United States and nine from other countries, all in Europe, but the price of roughly 4d. a page is, by the standards of research costs, very cheap.

C. R. TITTLE

## RULES FOR CHEMISTS

### Chemists and the Law

By F. A. Robinson and F. A. Amies. Edited by H. M. Bunbury. Pp. xx + 231. (London: E. and F. N. Spon, Ltd., 1967.) 40s. net.

THE term "chemist" in the context of this recent publication must very properly be accepted as covering a multitude of scientific disciplines, for there is much in this book which will prove of the greatest value and interest, not only to academic and industrial chemists, but to biochemists, physicists, pharmacists, engineers, factory managers and many others. Indeed, this book can also be strongly recommended for the earnest attention of the intelligent layman, because it provides a wealth of legal information regarding such diverse matters as "Contracts of Employment", "Negligence", "Pollution", "Food Statutes", "Agricultural Substances", "Explosives", "Medicines and Dangerous Drugs", "Radioactive Substances", "Patents", "Copyright" and so on. The legislative aspects of all these matters are discussed most authoritatively and comprehensively, particular attention being drawn to specific differences between the statute law of England and Wales as compared with the corresponding provisions of the Scotland and Northern Ireland Acts. Numerous legal cases are cited which constitute precedents and which provide the reader with some prognostication of the judgments which might conceivably be given when legal cases of a certain pattern come before the courts.

The organization of the British courts system is clearly outlined; details are given of the preparation for trial and hearing, of the duties and responsibilities of such people as expert witnesses, assessors and scientific advisers. The fundamental items of statute law, for example, Food and Drugs Act, Patents Act, and the provisions of a host of other important acts of parliament and statutory instruments are given in the greatest detail, accompanied

by extensive bibliographical references and explanatory notes. Public analysts, inspectors, and governmental scientific officers who have specific duties in the administration of the regulations of such acts will find this comprehensive book indispensable. Similarly, those individuals and organizations who have obligations in common law or under various statutes will find this publication an essential *vade-mecum*. In this complex technological age, it can be all too easy to become ignorant of the law, sometimes with dire consequences.

A well bound book with legible text, it is very reasonably priced at 40s. There has been a real need for a generic, specialist work of this kind and the demand is certain to be such that the first issue must soon be exhausted.

D. T. LEWIS

## ENZYME KINETICS FOR MEDICS

### Enzyme Kinetics

A Learning Program for Students of the Biological and Medical Sciences. By Halvor N. Christensen and Graham A. Palmer. Pp. viii + 124. (Philadelphia and London: W. B. Saunders Company, 1967.) 24s. 6d.

THIS is an excellent introductory book on enzyme kinetics. Its excellence stems from the fact that it explains in a simple and lucid manner the relationship between enzyme kinetics and physicochemical principles. Moreover, the basic principles of enzyme kinetics are explained in simple terms—it is not assumed, as it is in many books, that basic principles are so well understood that they do not have to be explained. This is particularly important in teaching enzyme kinetics to medical students whose background knowledge of physical chemistry is usually poorer than those of other biological students. The book concentrates almost exclusively on the effects of substrate and inhibitors on enzyme activity with brief reference to pH and temperature effects. But this severe restriction to specific topics is advantageous, in that with a few hours concentrated effort the elementary basis of enzyme kinetics should be clear.

My impression from teaching preclinical medical students, who are so busy with their major subjects of anatomy and physiology that they have little time for anything else, is that unless a particular subject is written clearly and concisely they prefer to learn the essentials in a "parrot-fashion" without understanding the subject. This book by Christensen and Palmer should go a long way in solving this problem with respect to enzyme kinetics.

It is interesting that the authors touch on the subjects of biological transport and chemotherapy, hinting at the possible future applications of enzyme kinetics. I think this is a particularly relevant point to the importance of enzyme kinetics for medical students: in the not too distant future knowledge of metabolic regulation of enzyme catalysis may lead to a more rational approach to chemotherapy, and the medical practitioner may require some knowledge of enzyme kinetics in order to understand the mode of action of his drugs. It is perhaps important to stress that medical students being taught at the present time will be practising their medicine well into the twenty-first century.

The book is, in fact, a learning programme, but the contents are so well organized that it makes excellent reading material. The judicious repetition provided by the programme aids the retention of the subject matter, whereas the question-answer routine of the programme continually stimulates one's interest.

Finally, it should be stressed that it is only an introductory book, but serves this purpose admirably, both for explanation of the subject and for stimulation of interest in enzyme kinetics.

E. A. NEWSHOLME

## VIROLOGY DOUBLE

### General Virology

By Salvador E. Luria and James E. Darnell, jun. Second edition. Pp. xv + 512. (New York and London: John Wiley and Sons, 1967.) 100s.

### Perspectives in Virology

Virus-Directed Host Response. Edited by Morris Pollard. (The Gustav Stern Symposium.) Pp. xxvi + 344. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 84s.

LURIA's *General Virology* first appeared in 1953, and it is indicative of the quality of this work that it should have held its position as an excellent textbook for fourteen years. The second edition, written with a collaborator, follows the same general plan, using many of the same chapter headings, but it is extensively rewritten and is some eighty pages longer. The book is well illustrated with many photographs and clear diagrams, and several large tables help to bring out the underlying theme of the book, which is the essential unity underlying animal, plant and bacterial viruses.

The definition of a virus is more complex than that given in the earlier edition, and emphasizes the concept of parasitism at the genetic level. Every virus has two essential attributes, the genome, the genetic material of a virus, either DNA or RNA, which reproduces inside living cells and behaves as part of the host cell; and the virion, the specialized particle produced in the cell and used to transfer the genome to other cells. An extreme case of parasitism at the genetic level is represented by the genome of a temperate bacteriophage which may become physically integrated into the chromosomes of the host bacterial cells, its presence being carried through generations of bacterial cell divisions in a non-infectious form. A related form of parasitism occurs when animal cells are transformed by polyoma virus, the dividing cells continuing to produce at least part of the polyoma genome but no complete polyoma virions. Rous sarcoma virus is apparently a defective virus in that the genome is unable to produce mature virions unless the cell is also infected with a helper virus which completes the maturation process of RSV virions in addition to forming more helper virions. The experimental work underlying these different forms of parasitism is summarized in the text, and the interpretation of laboratory results is set out with commendable clarity. Students of virology, whatever their particular discipline or vintage, should benefit from reading this excellent book.

The second book, the proceedings of a symposium, is entirely different in character. Of sixteen papers presented on the theme of virus-directed host response, those by W. P. Rowe and P. K. Vogt are particularly notable. Rowe's paper on defective animal viruses is rather speculative, presenting preliminary results on four examples of helper-sensitive defective animal viruses. This is one of the growing points of virology at the present time, and it is clear from the published discussion which followed the paper that there is great interest and activity in this field. Vogt analyses the meaning of the title of the symposium and recognizes two different types of virus-directed host responses, which he terms "submissive" and "defensive". The first implies control and direction of the host metabolism by the viral genome, which may lead to malignant transformation of the cell. The second type does not require viral genetic activity in the host cell, and is exemplified by host reactions such as antibody and interferon production. This paper contains a mass of detail, and provoked active discussion by the other participants. This reporting of the discussion is one of the most valuable aspects of the proceedings of symposia, which too often tend to be re-presentations of previously published work.

J. S. PORTERFIELD

## NUCLEIC ACIDS AND PROTEINS

### Genetic Elements

**Properties and Functions.** Edited by D. Shugar. (Symposium held on the occasion of the Third Meeting of the Federation of European Biochemical Societies, Warsaw, April 4-7, 1966.) Pp. ix+361. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc.; Warsaw: PWN-Polish Scientific Publishers, 1967.) 84s.; \$15.

THE book is a fascinating collection of fifteen articles concerned with recent developments in the structure of nucleic acids, their replication, the genetic code and the mechanism of protein synthesis. The organizers of the symposium attempted to select topics which were of direct interest not only to the specialists but also to as many of the participating biochemists as could be envisaged. It is perhaps partly because of this policy that, despite the title, there is little concern with chromosomes, mutation, recombination, genetic suppression, regulatory mechanisms or the transcription of DNA into RNA. Nevertheless, the limited range has enabled the editor and contributors to produce a valuable and coherent book.

Several papers are concerned with the structure of nucleic acids. Fuller reviews the conclusions obtained from X-ray work on solid materials and includes an interesting study of the interaction between DNA and certain antibiotics. Luzzati, Witz and Mathis describe the value of X-ray techniques in determining the conformation of nucleic acids in solution. G. L. Brown, Lee and Metz discuss the study of active sites in RNA by chemical modification. Zachau, Dütting and Feldmann give an account of the techniques used in their determination of the primary sequence of serine transfer RNA and undertaken simultaneously with Holley's work on alanine RNA. Engelhardt and his collaborators describe important parallel Russian work on the valine transfer RNA leading to a probable primary structure which is essentially confirmed by the results of further work added at the proof stage. Perhaps because of a shortage of time at the meeting, neither of these two papers refers to conceivable secondary structures of transfer RNA such as the clover-leaf model that is now receiving much attention. In an important short paper, Sanger and Brownlee describe their extremely powerful methods for the fractionation and identification of radioactive oligonucleotides. These methods have more recently (*Nature*, 215, 735; 1967) led to the determination of the primary sequence of the 5S ribosomal RNA.

Borst, Kroon and Ruttenberg describe their own and other work on mitochondrial DNA and consider the relation between mitochondrial and nuclear DNA and the genetic function of cytoplasmic DNA in general. Bollum rather briefly discusses the replication of DNA while Martin attempts to reconcile the large volume of work on the replication of viral RNA in various systems. The genetic code and mechanisms of protein synthesis are considered in four papers given by Khorana, by Matthaei and his colleagues, by Ochoa and his collaborators, and by Monro, Maden and Traut. Littauer and Revel describe their work on the possible function of the methyl groups in transfer RNA. The only genetic map in the book is given by Yaniv and Gros in their fascinating paper on modified aminoacyl RNA synthetases in temperature conditional mutants of *Escherichia coli*. The discussion which followed each paper is recorded and this includes some pertinent invited comments by Leder and Clark on synonymous codewords and on phasing mechanisms.

The book has been produced well, although the print is more difficult to read than the styles of type that are usually used by Academic Press. Although the numbering of pyrimidine rings is only referred to occasionally, it is unfortunate that among the various papers two different numbering conventions have been used.

As a whole, the book gives an impression of high scientific quality. New information is presented and discussed in a stimulating and balanced manner in relation to pertinent work from other laboratories. Many useful references are given and there is both a subject and an author index. It should prove to be a valuable guide to many aspects of nucleic acid biochemistry.

K. BURTON

## INVERTEBRATE NEUROPHYSIOLOGY

### Invertebrate Nervous Systems: their Significance for Mammalian Neurophysiology

Edited by C. A. G. Wiersma. Pp. ix+370. (Chicago and London: The University of Chicago Press, 1967.) \$10; 72s. net.

THIS symposium volume contains twenty-seven papers on various aspects of invertebrate neurophysiology. About half of these, comprising just over two-thirds of the book, review recent progress in limited parts of the field. This type of article seems to be particularly suited to inclusion in a symposium volume, because it is less extensive and more detailed than the orthodox review article. The remainder of the book consists of brief reports on particular investigations, the matter of which, I suspect, will shortly appear at greater length in their proper place, in journals devoted to the publication of original observations.

The longer articles between them cover a considerable slice of invertebrate neurophysiology. G. A. Kerkut gives a useful account of recent work on the pharmacology and ionic bases of synaptic transmission in molluscan neurones, and F. Strumwasser considers the types of information that may be stored in them. M. J. Cohen describes his work on the RNA metabolism of regenerating insect neurones. Some of the ways in which the nervous system controls the development of arthropods are described by J. S. Edwards. I. R. Hagadorn gives a brief review of neurosecretory mechanisms, and I. M. Cooke describes his experiments on the relation between electrical activity and secretion in neurosecretory axons. Non-striated muscles are examined by C. L. Prosser, and G. Hoyle delivers a polemic against the assumption that all striated muscles are like the frog sartorius.

All these different approaches are concerned, more or less, with physiological analysis at the cellular level. The usefulness of invertebrate material for this type of study is two-fold. First, many individual invertebrate neurones are larger and more accessible than those of vertebrates. Consequently, certain physiological problems may be much more easily solved by the use of invertebrate material; our knowledge of the mechanism of nervous conduction, to pick the most obvious example, would be much less advanced than it is if it were not for the giant axons of squids. Second, the study of a variety of different types of cells serves to indicate the variety of possible types of neuronal activity. An example of this is provided by the discovery of electrically transmitting synapses in invertebrates; the possibility of such electrical transmission must now be borne in mind by anyone investigating neuronal interaction in vertebrates.

Other approaches are concerned with the properties of systems rather than individual units. Here the great advantage of most invertebrate nervous systems is their relative simplicity in comparison with those of vertebrates. Their investigation, therefore, may provide us with models of how parts of the vertebrate nervous system work. The remainder of this volume is concerned with studies of this type.

G. M. Hughes and W. D. Chapple describe the interconnexions of neurones in the ventral nerve cords of crustaceans and the ganglia of gastropod molluscs. The organization of central ganglia is discussed by D. M. Maynard in an article which includes a most interesting comparison of the control of cephalopod colour patterns

with the visual perception of pattern. C. A. G. Wiersma describes the processing of visual information in crustacea. D. M. Wilson discusses the control of rhythmic behaviour in flying locusts and running cockroaches; the central control of more complex behaviour is reviewed by F. Huber. J. Z. Young compares the nervous systems of cephalopod molluscs and mammals, especially with reference to his views on the mechanism of learning.

This volume, then, gives a good account of many of the problems which interest invertebrate neurophysiologists at the present time. Its stated aim, however, is more than this, in that it claims to deal with the significance of its subject in relation to mammalian neurophysiology. It is disappointing to have to state that it does not succeed in this, because the majority of the articles (those by Maynard, Young and Wiersma are exceptions) make little attempt at the comparison. The mammalian neurophysiologist may well find the contents interesting, but for the most part he will have to work out their significance for himself.

D. J. AIDLEY

## FOREST ECONOMY

### Forest Planning

By D. R. Johnston, A. J. Grayson and R. T. Bradley. Pp. 541. (London: Faber and Faber, Ltd., 1967.) 126s.

THE outstanding interest of this book is that it is based on a study of the principles, policy and main methods used by the Forestry Commission of Great Britain which is now engaged not merely in afforestation but in the full management of the extensive forests created since 1919. Consequently, the authors have shown a new and more realistic, commercial approach to forest management. Classic forest management has been chiefly concerned with the capital value and structure of the forest growing stock and its silvicultural management, whereas now the authors are also greatly concerned with labour costs which constitute so large a part of the capital invested in a managed forest. Forestry must be competitive with other enterprises and must therefore reduce labour intensity, analyse and respond to cost/benefit ratios and to price and demand, and organize and time the thinnings, final fellings and other operations in relation to profit.

The first part of the book deals with policy, in particular the past and present role of forestry in Britain. Here, in an otherwise valuable section, there is perhaps some confusion between basic purpose and policy—the means of accomplishing a purpose—and it seems a pity that basic forest values which provide the fundamental purposes of forestry to various types of owner are not studied and analysed before policy is considered.

The second part of the book deals with planning and analyses many of the practices and problems of forestry. There are particularly valuable studies of investment criteria, costs and benefits, the influence of time and consequent interest charges on nearly all forest operations and their effect on the internal rate of return. The calculation of net discounted revenue is clearly presented and a chapter is devoted to its use in the particularly important matter of deciding the time of final fellings, and there is another valuable chapter on the economics of thinnings. Some foresters may, however, think that the ecological values of mixed, and even irregular, and mainly indigenous naturally regenerated crops are too easily rejected in favour of pure, artificially regenerated and often exotic stands with their apparent substantial commercial advantages without undue risk.

The third and fourth parts of the book describe the application of planning, by administrative organization and working plans, and the collection of data. There is a very useful chapter on incentives for and movement of labour and an appendix on the productivity of labour. The chapter on accounts and cost accounting could have been improved by a study of the problems of presenting a

proper balance sheet for a forest enterprise and its growing stock.

The book is excellent, thought provoking yet practical and informative for all professional foresters and for more advanced students. The book is well produced, with many diagrams, tabular statements and a host of interspersed references.

F. C. OSMASTON

## TEACH YOURSELF BIOLOGY

### The Science of Biology

By Paul B. Weisz. Third edition. Pp. xxiii + 886. (New York: McGraw-Hill Book Company, Inc.; Maidenhead: McGraw-Hill Publishing Company, Ltd., 1967.) 80s.

### Bioscience

By Robert B. Platt and George K. Reid. (Reinhold Books in the Biological Sciences.) Pp. xvi + 528. (New York and London: Reinhold Publishing Corporation, 1967.) 76s.

BOTH these volumes are designed for the first year American college student. They are comprehensive surveys of current biology theory, doubtless intended to accompany parallel courses of laboratory work. There are many such books on the market and they need continual revision to keep abreast of the extraordinarily rapid development of their subject. These two books are reminiscent of an admirable symposium, *The Science of Life*, by Wells, Huxley and Wells, which was published in Great Britain in the 1930s and presented an equally encyclopaedic view of "biology" as it then was. This comparison emphasizes the many discoveries and new concepts which have changed our biological outlook in the three intervening decades.

*The Science of Biology* is an attractively produced, comprehensive post-A level primer, lucid and readable. It comprises two well-balanced parts, roughly analogous to the traditional "Structure and Function", "The Organization of Life" and "The Operations of Life". After a brief preamble on the meaning of biological science, the four sections of the first part proceed in logical sequence from the basic physical and chemical detail of matter through cell structure to organism, species, population, ecosystem, community, biosphere and habitat, culminating in a classification of living forms. The second part covers metabolism, self-perpetuation and the controls and co-ordination involved in the maintenance of steady states, reproduction, heredity and evolution. Verbal statements are supplemented and reinforced with a great deal of original diagrammatic presentation and the work is pleasingly illustrated throughout by line drawings and coloured photographs. At the end of each chapter are searching review questions on its content and very full lists of references for collateral reading; there are a useful glossary and a functional index. The book is a fully revised version of two previous editions and has a scholarly sophistication and objectivity which appeal to the initiated.

*Bioscience*, though similar in scope and intention, is perhaps more a beginner's book and presents its subject matter in more traditional sequence—a "blue" as contrasted with a "yellow" version. The editor claims that it is a modern, realistic account of the nature, structure, function and interactions of the organisms of this planet with their environment, with each other and, particularly, with man. The parts of the book survey, in succession, the diversity of life, organization into populations, communities and ecosystems, molecular and cellular biology, organ systems, plant and animal organisms, genetics and evolution. The book concludes with a chapter on man's place in the world ecosystem. The authors maintain that their arrangement is flexible and that different teachers could adapt it to suit their own courses. The text is illustrated by line diagrams and black-and-white photographs. There is a reading list, correlated with the various sections,

at the end of the book, and a useful index. A "statement of principle" and a historical orientation precede each chapter.

E. J. VINNICOMBE

## SCHOLASTIC COSMOGONY

### Summa Theologiae

(Latin Text and English Translation, Introductions, Notes, Appendices and Glossaries.) By St. Thomas Aquinas. Edited and translated by William A. Wallace. Pp. xxiii + 255. (London: Eyre and Spottiswoode; New York: McGraw-Hill Book Company, 1967.) 42s.

THE editor and publishers have done a notable service to both men of science and historians in producing this volume in their series of translations of the celebrated *Summa* of St Thomas Aquinas (1225-74). In all fairness, as the text is at pains to point out, certain reservations must be accepted if this example of mediaeval writing is to be appreciated at its true value. The first is that it is in the nature of a museum piece. Nobody, at any stage of sophistication, would rate it very highly, either for its originality or as a major contribution to scientific thought. That much was obvious to later commentators. Neither was it intended as an all-embracing treatment of Aristotelian physics such as that provided for the monks by Albertus Magnus. Its author was a theologian first and foremost, resolved upon an attempt, as heroic as it was profound, to fit the cosmogony of his age to the tenets of the Catholic Church. But St Thomas exhibits one characteristic different from the outlook of the patristic doctors: he shows great reluctance to commit himself to any one theory of creation (and there were many); he preserves a remarkably open mind as he examines in detail the *hexaemeron*, namely, the six (active) days of creation of the Genesis story.

The editor provides the Latin text and English translation on opposite pages—not a completely word for word translation, but one in careful harmony with the original syntax. From the whole assemblage there emerges a deep tension which St Thomas realizes with devastating honesty. It is that the unfolding of creation as presented in the Book of Genesis was a kind of metaphysical exercise, the primary purpose of which seems to have been to discover the Creator. (In any case, it is unlikely that we shall ever know exactly what the inspired writer was trying to convey.) The chasm between that view and ours is stupendous. Nevertheless, odd as it may appear, the development of subsequent theories, bizarre and irrational as most of them were, paved the way for Galileo and all who followed. St Thomas himself notes, with marked erudition, all the controversies of his time and those of former epochs. In one respect at least he is a mild rebel in preferring the more "scientific" Aristotle to the purely philosophical Plato. In this we discern the precursor of descriptive and taxonomic methods, later to fructify into medical research. There was an acute awareness of "foreign" influences, even the *Guide for the Perplexed* by Maimonides.

If this were all, however, we should not be much the wiser in 1967, and the editor's efforts would be judged as sadly unrewarding. But luckily, that is far from the case. The fact is that St Thomas Aquinas stands revealed as the forerunner—by about six and a half centuries—of D'Arcy Wentworth Thompson and his *On Growth and Form*, now available as a Cambridge paperback. For example, the early fathers knew the essentials of the social habits of bees, centuries later to become a focus of mathematical research into problems of symmetry and close-packing. Again, engineers make allowance, even during construction, for the stresses and strains inseparable from those which the finished edifice will have to sustain, an analogue of an expanding creation of which we find traces in primitive thought.

In brief, nobody is likely to derive very much profit from reading St Thomas's *Cosmogony* in isolation. If, however, one takes it in one hand, and a copy of *On Growth and Form* in the other, then there is a treat in store.

The Queen of Sheba, at the court of King Solomon, is said to have exclaimed that "the half was not told me". Even today, she would not be far wrong.

F. I. G. RAWLINS

## RESTRICTED COGNITIONS

### Cognitive Consistency

Motivational Antecedents and Behavioral Consequents. Edited by Shel Feldman. Pp. xiii + 312. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.) 68s.

TEN American social psychologists wrote the nine chapters of this volume. Their theme, stated in a useful introductory review by W. J. McGuire, is the notion that a person tends to minimize internal inconsistencies among his beliefs, feelings and actions. The material is not well presented. Much of the writing is wordy and obscure. Some of the factual information would have been better published in original papers in specialist journals. For example, S. Feldman, in a chapter entitled "Motivational Aspects of Attitudinal Elements, and their Place in Cognitive Interaction", describes an investigation to test "whether belief strength or importance is a better predictor as to which of the belief statements will be retained in the response set from one test to the next". This was done by asking people at the Pennsylvania State Farm Show about their views on whole milk and skim milk. The figures obtained are given complete with a value for *t* and other statistics. The results "seem to confirm the hypothesis that the measurement of the importance of a cognitive element may be differentiated from the measurement of its belief strength, as well as from its salience".

Some important topics are touched on. E. Aronson ("The Psychology of Insufficient Justification") describes an experiment with children on the effects of threat either of severe punishment or of mild punishment. The latter had the greater influence on behaviour. Other important questions include the character of responses to skin colour, discussed by M. Fishbein ("Beliefs, Attitudes, and Behavior"), and the effects of large, propagandist generalizations, discussed by R. P. Abelson and D. E. Kanouse ("Subjective Acceptance of Verbal Generalization"). These passages lead, however, to no decisive conclusions or guides to social action.

There is surprisingly little comment on relevant matters outside the range of social psychology in its narrowest sense. J. E. Singer ("Motivation for Consistency") does raise some physiological questions, in a chapter which is on a consistently high level of abstraction. At the other end of the psychological spectrum, a reader might well look here for a coherent review of the role, if any, of psychoanalytic concepts in this field, but he would find only a single paragraph by A. Pepitone ("Problems of Consistency Models") and a mention by Feldman. Other cognate topics barely mentioned include the effects of sensory deprivation and the related notion of the "drive for stimulation".

The general impression is of a great deal of talent trapped in an unnecessarily restricting theoretical framework. The authors themselves are obviously discontented with their own achievements. K. E. Weick, at the end of his chapter ("Task Acceptance Dilemmas"), writes: "Whether... the approach will be productive remains to be seen". M. J. Rosenberg ("Some Limits of Dissonance") describes his conclusions as "debatable propositions". And W. J. McGuire suggests "that perhaps we have not answered any question to anyone's satisfaction". S. A. BARNETT

## University News :

### Australian National

PROFESSOR F. FENNER, at present professor of microbiology in the John Curtin School of Medical Research, has been appointed head of the school in succession to Sir Hugh Ennor, who was appointed secretary to the Department of Science and Education of the Commonwealth of Australia earlier this year.

### Loughborough

PROFESSOR E. J. RICHARDS, professor of applied acoustics and director of the Institute of Sound and Vibration Research in the University of Southampton, has been appointed vice-chancellor of the university in succession to Dr H. L. Haslegrave, who retires on September 30.

### Memorial

DR K. B. ROBERTS, at present reader in physiology in the London Hospital Medical College, has been appointed associate dean of medicine and head of the Department of Physiology in the Memorial University of Newfoundland, and will take up his appointment in September 1968.

### Nottingham

PROFESSOR E. MAURICE BACKETT, at present professor of social medicine and head of the Department of Public Health and Social Medicine in the University of Aberdeen, has been appointed to the chair of community health in the medical school.

## Appointments

DR S. FAWCETT, at present director of Battelle-Northwest, has been appointed executive vice-president of Battelle Memorial Institute, and Dr F. Albaugh has been appointed director of the Pacific Northwest Laboratory of the Battelle Memorial Institute.

DR E. E. FERGUSON has been appointed director of the Aeronomy Laboratory of the US Environmental Science Services Administration's research laboratories in Boulder, in succession to Dr E. K. Smith.

## Announcements

THE following awards have been announced by the Gairdner Foundation: DR C. R. DeDUVE, professor of chemistry in the Rockefeller University, a \$20,000 special award of merit for the discovery of minute structures inside cells called lysosomes; DR G. E. PALADE, professor and head of the Laboratory of Cell Biology in the Rockefeller University, a \$20,000 special award of merit for his contribution to the understanding of the synthesis and movement of protein destined for export in cells; DR M. NIRENBERG, chief of the Laboratory of Biochemical Genetics, US National Institutes of Health, a \$20,000 special award of merit for demonstrating the method of manufacture of protein within cells, and some of the ways in which the rate of production and the composition of various proteins are controlled inside the cell; DR D. H. COPP, professor and head of physiology in the University of British Columbia, and DR I. MACINTYRE, professor of endocrine chemistry and joint director of the Endocrine Unit, Royal Postgraduate Medical School, London, share equally a \$5,000 annual award, Dr Copp for his discovery of a new hormone called thyrocalcitonin and Dr MacIntyre for demonstrating that this hormone is produced by cells present in the thyroid gland; DR P. J. MOLONEY, a consultant at Connaught Medical Research Laboratories, Toronto, a \$5,000 annual award for his study of the structure of insulin; DR J. AXELROD, chief of the section on pharmacology, Laboratory of Clinical Science, US National Institutes of Health, and DR S. UDENFRIEND, chief of the Laboratory of Clinical Biochemistry, US National Institutes of Health,

share equally a \$5,000 annual award for their study of chemical reactions in the body which lead to the detoxication of drugs and the handling of certain active chemicals which may be concerned with the control of blood pressure and the activity of the cardiovascular system; DR J. FRASER MUSTARD, professor of pathology in McMaster University, a \$5,000 annual award for his work in arteriosclerosis.

THE exhibition "The History and Development of Geological Cartography", which opened on July 28, is on display to the public until October 27, Monday to Friday, 9-5 pm, in the University Library, Whiteknights, Reading. This exhibition of geological maps is in honour of the eightieth birthday of Emeritus Professor H. L. Hawkins.

ERRATUM. In the article "Half-lives of Peptides and Amines in the Circulation" (*Nature*, 215, 1237; 1967), the first sentence of the third paragraph on page 1238 should read: "The design of the experiments to find the half-life of bradykinin in the circulation of the cat was as follows".

# CORRESPONDENCE

## What is Science Policy?

SIR,—On my return from an overseas business tour attempting the difficult task of selling European aircraft in the United States, I have seen in your issue of September 2 your leading article "What is Science Policy?" (*Nature*, 215, 1013; 1967), and I would like to challenge the point you make about Concord.

It has never been suggested that the full cost of Concord research and development will be recovered through aircraft sales, although I believe personally that at least a very substantial recovery will be made. With Concord Britain and France have a real opportunity of securing a worthwhile share in the civil aircraft market, a major growth market.

Our detailed market assessments based on realistic even pessimistic premises (such as, for example, the assumption that there will be a complete ban on overland supersonic cruise) indicate a minimum market of 200 Concorde by 1975, rising to a possible 350/400 by 1980. These estimates are borne out by independent American market research. The sale of 200 Concorde would represent a contribution of at least £100 million annually for seven years to Britain's balance of payments, and you would probably concede that this would be "some kind of economic return".

As a direct result of Concord research and development expenditure, advanced technological activities have been initiated and pressed forward in many and diverse fields in materials, electronics, miniaturization, automation machine tools, computerized operational research and structural test techniques, to give a random selection. The greater part of this work has a direct applicability and value for industrial fields other than aviation, but, as you will appreciate, this value cannot be expressly stated in money terms.

In a recent speech Mr. Wedgwood Benn said: "Foreign defence expenditure is strengthening the advanced technology of our competitors and losing us export markets". Everyone who is trying to sell in international markets knows this is true. Concord expenditure is already doing much, and will do more, to improve our competitive position.

Yours faithfully,

E. H. BURGESS

British Aircraft Corporation (Operating), Limited,  
Filton Division,  
G.P.O. Box No. 77,  
Filton House, Bristol.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, October 2

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 9.30 a.m.—Colloquium on "Definition, Realization and Use of Time and Frequency".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Mr. D. K. S. Bain: "Power System Model".

INSTITUTION OF MECHANICAL ENGINEERS, STEAM PLANT GROUP (at 1 Birdcage Walk, Westminster, London, SW1), at 6.30 p.m.—Discussion Meeting on "The Combination of the Gas Turbine and Industrial Steam Production".

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at Shell Centre Theatre, Shell Centre, London, SE1), at 6.30 p.m.—Scientific Films.

## Tuesday, October 3

BRITISH BIOPHYSICAL SOCIETY, PHYSICAL BIOCHEMISTRY GROUP (at Queen Elizabeth College, Campden Hill Road, London, W8)—Meeting on "Dielectric Properties of Biological Macromolecules".

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP—PHYSIOCHEMICAL AND BIOPHYSICAL PANEL (at 14 Belgrave Square, London, SW1), at 5 p.m.—Dr E. J. Crisp: "Physicochemical Aspects of the Settlement of Marine Larvae".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Dr P. R. Thornton: "The Use of the Scanning Electron Microscope in Device Physics".

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Automatic Control Group of the Institution of Mechanical Engineers, at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion meeting on "Instruments and the Mechanical Engineer", opened by Mr L. Finkelstein.

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP (in association with the Chemistry Department, Birkbeck College, at Birkbeck College, London, WC1), at 6 p.m.—Dr E. Horowitz: "Synthesis and Properties of Co-ordination of Polymers containing Transition Metals".

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMATIC CONTROL GROUP (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "Instruments and the Mechanical Engineer".

POLAROGRAPHIC SOCIETY (in Room 111, The University of Surrey, Battersea Park Road, London, SW11), at 6.30 p.m.—Dr D. Inman: "Some Recent Applications of Chronopotentiometry".

## Wednesday, October 4

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP (joint meeting with the Manchester Section, at the University of Manchester Institute of Science and Technology), from 10.30 a.m. to 4.30 p.m.—Meeting on "Plastics in Building".

COLOUR GROUP (Great Britain) (in the Physics Department, Imperial College, London, SW7), at 2.30 p.m.—Forty-fifth Science Meeting. Report on the 36th Annual Meeting of the Inter-Society Colour Council in New York—June 1967. Report on the 16th Session of the Commission Internationale de l'Eclairage held in Washington—June 1967.

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W1), at 5.30 p.m.—Mr K. Reiser: "The Control of Corrosion in Refinery Distillation Units".

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS (at 8-9 Bedford Square, London, WC1), at 6 p.m.—Dr David Pye: "Animal Sonar".

SOCIETY OF CHEMICAL INDUSTRY, OILS AND FATS GROUP (at 14 Belgrave Square, London, SW1), at 6.15 p.m.—Dr F. B. Padley: "The Use of a Flame-ionization Detector to Detect Components Separated by T.L.C."; Dr P. A. T. Swoboda: "Gas Chromatographic Analysis of Food Fats and Flavour".

SOCIETY FOR ANALYTICAL CHEMISTRY (in the Department of Mechanical Engineering, Imperial College, London, SW7), at 7 p.m.—Professor R. Belcher: "Some New Reagents and Reactions in Analytical Chemistry".

## Wednesday, October 4—Thursday, October 5

INSTITUTION OF MECHANICAL ENGINEERS, THERMODYNAMICS AND FLUID MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, SW1)—Symposium on "Subsonic Fluid Flow Losses in Complex Passages and Ducts".

## Thursday, October 5

ROYAL INSTITUTION (at 21 Albemarle Street, London, W1), at 2.30 p.m.—Professor George Porter, F.R.S.: "Matter and Motion" (Civil Service Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Sir Stanley Brown, C.B.E.: "The Fascination of Electrical Power Engineering" (President's Inaugural Address).

## Friday, October 6

CARWORTH EUROPE (in the Large Lecture Theatre, Physiological Laboratory, Downing Street, Cambridge), at 9.30 a.m.—Second Annual Symposium on "The Interaction of the Laboratory Animal with its Microflora".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Dr H. P. Williams and Mr A. N. Ince: "The Range of L.F. Transmissions Using Digital Modulation".

SOCIETY OF CHEMICAL INDUSTRY, FINE CHEMICALS GROUP (at 14 Belgrave Square, London, SW1), at 6.30 p.m.—Professor Sir Ewart Jones, F.R.S.: "Biosynthetic Studies on Natural Acetylenes".

## Monday, October 9

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION AND TRAINING GROUP (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "C.E.I. Examination Requirements—a Progress Report".

SOCIETY OF INSTRUMENT TECHNOLOGY (at the Royal Institution, 21 Albemarle Street, London, W1), at 6 p.m.—Sir Henry Jones, K.B.E.: "Sources and Uses of Energy" (Thomson Lecture).

## Monday, October 9—Thursday, October 12

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2)—Conference on "The Economics of the Reliability of Supply—a Comparison of Standards Adopted in Various Countries".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (mechanical engineer or physicist with a good honours degree and preferably some experience in experimental research and an interest in instrumentation) in the DEPARTMENT OF MECHANICAL ENGINEERING—The Registrar, King's College (University of London), Strand, London, WC2 (October 6).

ASSISTANT LECTURER IN PHILOSOPHY—The Registrar, University College, Cathays Park, Cardiff (October 7).

SENIOR EXPERIMENTAL OFFICER or EXPERIMENTAL OFFICER in the DEPARTMENT OF METALLURGY, to take charge of the electron microprobe analysis equipment, and to participate in the departmental research programmes that need microanalysis—The Registrar, The University of Manchester Institute of Science and Technology, Sackville Street, Manchester 1 (October 7).

ASSISTANT LECTURER (preferably with an interest in the field of psycholinguistics)—The Registrar, University Senate House, Bristol 2 (October 9).

CHAIR OF EDUCATION—The Secretary and Registrar, The University, Southampton (October 9).

RESEARCH ASSISTANT (with a degree or equivalent qualification and some knowledge of chemical methods) in the DEPARTMENT OF PHYSIOLOGY, to work with Professor G. R. Hervey on a project concerned with food intake and body composition in animals—The Registrar and Secretary, The University, Leeds, 2 (October 9).

HEAD (with suitable academic qualifications and preferably some industrial experience) of the DEPARTMENT OF MATHEMATICS—The Clerk to the Governing Body, Woolwich Polytechnic, Wellington Street, London, SE18 (October 11).

LECTURER IN THE PHILOSOPHY OF SCIENCE at St. Salvator's College—The Secretary, University of St. Andrews, College Gate, St. Andrews, Fife, Scotland (October 14).

READER (with research interests in some branch of fluid mechanics such as gas dynamics or plasma dynamics) in APPLIED MATHEMATICS—The Registrar, University of Strathclyde, George Street, Glasgow, C1 (October 14).

SCIENTIFIC INFORMATION OFFICER (with a degree in the biological or agricultural sciences and a knowledge of at least one other European language)—The Director, Commonwealth Bureau of Helminthology, The White House, 103 St. Peter's Street, St. Albans, Herts (October 15).

ASSISTANT KEEPER (with some training and interest in invertebrate zoology) in ZOOLOGY at the Manchester Museum—The Registrar, The University of Manchester, Manchester, 13, quoting Ref 138/67 (October 16).

RESEARCH FELLOW (with research experience) in the DEPARTMENT OF Natural History, to join a team of ecologists studying rook populations—The Secretary, The University, Aberdeen, AB9 1AS (October 16).

LECTURERS or ASSISTANT LECTURERS (2) (pure mathematicians) in MATHEMATICS—The Assistant Secretary, The London School of Economics and Political Science, Houghton Street, London, WC2 (October 19).

SENIOR LECTURER/LECTURER IN INORGANIC CHEMISTRY at Rhodes University, Grahamstown, South Africa—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (South Africa and London, October 23).

RESEARCH FELLOWS in the DEPARTMENTS OF PATHOLOGY AND SURGERY, University of Ibadan, Nigeria—The Inter-University Council, 33 Bedford Place, London, WC1 (October 26).

ASSISTANT LECTURER or RESEARCH ASSISTANT in MATERIALS SCIENCE in the DEPARTMENT OF MECHANICAL ENGINEERING—The Secretary of the University Court, The University, Glasgow (October 27).

LECTURER/SENIOR LECTURER IN PHILOSOPHY at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, October 27).

CHAIR OF ANATOMY; and CHAIR OF PHYSIOLOGY in the School of Medicine, University of Auckland, New Zealand—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (New Zealand and London, October 31).

CHAIR OF PHYSICS—The Registrar, University College of Swansea, Singleton Park, Swansea (October 31).

SENIOR LECTURER (with experience in geological dating or other isotope studies) in the ISOTOPE GEOLOGY UNIT—The Director, Scottish Research Reactor Centre, East Kilbride, Glasgow (October 31).

CHAIR OF VETERINARY MEDICINE at the University of Sydney, Australia—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, November 13).

SENIOR PROFESSORS in the SCHOOL OF THEORETICAL PHYSICS—The Registrar, Dublin Institute for Advanced Studies, 10 Burlington Road, Dublin 4, Republic of Ireland (November 30).

ASSISTANT EXPERIMENTAL OFFICER (preferably with experience with chromatographic, electrophoretic and radioactive tracer techniques as applied to nucleic acids and proteins) to assist in chemical and biochemical studies of the structure and multiplication of animal viruses—The Secretary, Animal Virus Research Institute, Pirbright, Surrey.

BIOCHEMICAL ASSISTANT (with a general degree in biology) for research work on metabolism in renal disease—Professor H. E. de Wardener, Fulham Hospital, London, W6.

CHAIR OF ELECTRICAL ENGINEERING—The Academic Registrar, The City University, St. John Street, London, EC1.

MASTER TO TEACH MATHEMATICS to all levels, including Sixth Form and Open Scholarship work—The Master, Dulwich College, London, SE21.

RESEARCH ASSISTANT in the DEPARTMENT OF OCEANOGRAPHY, to work in a team engaged in a three year study of the physical processes of sediment transport in the ocean—The Deputy Secretary, The University, Southampton, SO9 5NH.

RESEARCH TECHNICIAN at the TENOVUS INSTITUTE FOR CANCER RESEARCH, Welsh National School of Medicine for cytodiagnosis—The Pathologist, The Group Laboratory, St. David's Hospital, Cardiff.

SENIOR LECTURERS or LECTURERS (2) (with special interests in analysis geometry or numerical analysis) in MATHEMATICS; a SENIOR LECTURER or LECTURER in STATISTICS; and a SENIOR LECTURER or LECTURER in COM-

**PUTTING—The Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N7.**

**TECHNICIAN** (with G.C.E. 'O' level in at least four subjects which should include English language, mathematics and another science subject, preferably physics, plus at least five years laboratory experience) in the **PAST NEUTRON GROUP** to assist in experimental work concerned with problems of radiation protection and neutron studies in the field of health physics. The Director, Radiological Protection Service, Clifton Avenue, Belmont, Sutton, Surrey.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

### Great Britain and Ireland

**National Institute of Agricultural Engineering.** Experimental Farm Buildings. Report No. 10: A Refrigerated Chilling House. By H. J. M. Messer, G. P. Franghiadi and Dr J. T. B. Sharrock. Pp. 15. (Slusoe, Bedford: British Society for Research in Agricultural Engineering, National Institute of Agricultural Engineering, 1967. Obtainable from H.M. Stationery Office.) 4s. 6d. [108]

**Chemico-Medical Abstracts.** Section D: Endocrinology, Vol. 1, No. 1. Edited by A. W. Saunderson and J. A. Duncan. Pp. 1-74. (D0001-D0304.) Annual subscription: £55; \$155. (London: Derwent Publications, Ltd., 1967.) [118]

**The Library Association.** Special Subject List No. 48: The History of Science and Technology—a Select Bibliography for Students. By K. J. Rider. Pp. 60. (London: The Library Association, 1967.) 20s. (L.A. members 15s.) [118]

**Scientific Principles and Moral Conduct.** By James B. Conant. (The Twentieth Arthur Stanley Eddington Memorial Lecture delivered at Princeton University, 15 November 1966.) Pp. 48. (London: Cambridge University Press, 1967.) 6s. net. [118]

**University of Southampton.** Annual Report of the Appointments Board, 1965-1966. Pp. 20. (Southampton: The University, 1967.) [118]

**BBC Engineering Monograph No. 68:** Recent Research on Studio Sound Problems. Part 1: A Subjective Investigation into Preferred Microphone Balances. By D. K. Jones. Part 2: The Design of a Low-Frequency Unit for Monitoring Loudspeakers. By H. D. Harwood. Pp. 23. (London: British Broadcasting Corporation, 1967.) 5s. [118]

### Other Countries

**Sveriges Geologiska Undersökning.** Översiktskartor med Beskrivningar. Berggrundskarta över Gävleborgs Län. (Map of Solid Rocks of the Gävleborg County.) Södra Bladet, Norra Bladet. By P. H. Lungegårdh. 60 kr. Avhandlingar och Uppsatser. Ser. C. No. 605: Geological Data from the Kristianstad Plain, Southern Sweden. By Kaj Nilsson. Pp. 32+9 plates. 15 kr. Ser. C. No. 610: Lower Viruan (Middle Ordovician) Conodonts from the Gullhögen Quarry, Southern Central Sweden. By Lars E. Fahraeus. Pp. 40 (4 plates). 6 kr. Ser. C. No. 613: On the Genus *Leptylaria* Wedekind 1937. By Erik Norling. Pp. 24 (4 plates). 6 kr. Ser. C. No. 614: The Minerals of the Silver Mines of Hällefors. By Nils Sundius, Alexander Parwel and Benita Rajandi. Pp. 20. 15 kr. Ser. C. No. 619: The Precambrian Quartzite in the Norberg District, Central Sweden, and Its Iron-Sand Bed, with Some Aspects of the Evolution of the Fennoscandian Supracrustals in Central Sweden. By Per Geijer. Pp. 36. 8 kr. Ser. C. No. 620: The Stora Sjöfjärds Iron Ore Deposit, Kaunisvaara, Northern Sweden. By Bo Lundberg. Pp. 37. 8 kr. Ser. Ca. No. 40: Beskrivning till Berggrundskarta över Kopparbergs Län. (Summary Description to Map of the Pre-Quaternary Rocks of the Kopparberg County, Central Sweden.) By Sven Hjeltnqvist. Pp. 217. Karta, 2 blad, med beskrivning, 90 kr. (Stockholm 50: Sveriges Geologiska

Undersökning, 1966 and 1967. Distribution: Svenska Reproduktions AB, Fack Vällingby 1.) [75]

**Board of Grain Commissioners for Canada, Winnipeg.** Grain Research Laboratory—1966 Report. Pp. v+89. (Ottawa: Queen's Printer, 1967.) [88]

**Serial Atlas of the Marine Environment.** Folio 13: Distribution of the Euphausiid Crustacean *Meganyctiphanes norvegica* (M. Sars). By John Mauchline and Leonard R. Fisher. Pp. 3+3 plates. \$5. Folio 14: Distribution of North Atlantic Pelagic Birds. By Robert Cushman Murphy. Pp. 4+8 plates. \$8. (New York: American Geographical Society, 1967.) [88]

**Sveriges Geologiska Undersökning.** Översiktskartor med Beskrivningar. Ser. Ba, Nr. 22: Berggrunden i Gävleborgs Län. (Petroleum of the Gävleborg County in Central Sweden.) By Per H. Lungegårdh. Pp. 303. 30 kr. Avhandlingar och Uppsatser. Ser. C, Nr. 615: Die Geologie der Sulidierz-lagerstätte Kalvbacken, Mittelschweden. (Geology of the Kalvbacken Sulphide Ore Deposit, Central Sweden.) By Helmut Hübner. Pp. 85+1 plates. 25 kr. (Stockholm 50: Sveriges Geologiska Undersökning, 1966 and 1967. Distribution: Svenska Reproduktions AB, Fack Vällingby 1.) [8-]

**Commonwealth of Australia.** Department of National Development: Bureau of Mineral Resources, Geology and Geophysics. Report No. 88: Geology of the South-Eastern Part of the Amadeus Basin, Northern Territory. By A. T. Wells, A. J. Stewart and S. K. Skwarko. Pp. 59+11 plates. Report No. 111: Magnetic Mean Hourly Values from Watheroo Observatory, Western Australia, 1951-1952. By P. M. McGregor. Pp. vi+116. Report No. 120: Magnetic Mean Hourly Values from Watheroo Observatory Western Australia, 1957-1958. By P. M. McGregor. Pp. vi+116. (Parkes A.C.T.: Bureau of Mineral Resources, Geology and Geophysics, 1966.) [108]

## HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one or two copies of NATURE each week is:

### \*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire.....£14.0.0 each  
United States of America.....(by air freight).....\$44 each  
Canada.....(by air freight).....\$47.80 each  
Elsewhere overseas by surface mail.....£13.15.0 each

(Charge for delivery by air mail on application)

\*Shorter periods *pro rata*. (Minimum three months.)

### MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

### \*12 MONTHS (52 issues and 4 indexes)

Number of Copies	G.B. & Eire	U.S.A.	Canada	Elsewhere
	(by air freight)	(by air freight)	(by air freight)	(surface mail)
3-5	Each £13.10.0	Each \$42	Each \$46.00	Each £13.10.0
6-11	£12.15.0	\$40	\$43.60	\$12.15.0
12 or more	£12.0.0	\$38	\$41.70	£12.0.0

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)
